Package ‘ADMMsigma’

August 2, 2018

Type Package

Title Penalized Precision Matrix Estimation via ADMM

Version 2.1

Date 2018-07-31

Description Estimates a penalized precision matrix via the alternating direction method of multipliers (ADMM) algorithm. It currently supports a general elastic-net penalty that allows for both ridge and lasso-type penalties as special cases. This package is an alternative to the ‘glasso’ package.

Description

Penalized precision matrix estimation using the ADMM algorithm. Consider the case where \(X_1, \ldots, X_n\) are iid \(N_p(\mu, \Sigma)\) and we are tasked with estimating the precision matrix, denoted \(\Omega \equiv \Sigma^{-1}\). This function solves the following optimization problem:

**Objective:** \(\hat{\Omega}_\lambda = \arg\min_{\Omega \in S_p^+} \left\{ \text{Tr} (S\Omega) - \log \det (\Omega) + \lambda \left[ \frac{1-\alpha}{2} \|\Omega\|_F^2 + \alpha \|\Omega\|_1 \right] \right\} \)

where \(0 \leq \alpha \leq 1\), \(\lambda > 0\), \(\|\cdot\|_F\) is the Frobenius norm and we define \(\|A\|_1 = \sum_{i,j} |A_{ij}|\). This elastic net penalty is identical to the penalty used in the popular penalized regression package glmnet. Clearly, when \(\alpha = 0\) the elastic-net reduces to a ridge-type penalty and when \(\alpha = 1\) it reduces to a lasso-type penalty.

Usage

```
admmsigma(X = NULL, S = NULL, nlam = 10, lam.min.ratio = 0.01,
            lam = NULL, alpha = seq(0, 1, 0.2), diagonal = FALSE, path = FALSE,
            rho = 2, mu = 10, tau.inc = 2, tau.dec = 2, crit = c("ADMM",
            "loglik"), tol.abs = 1e-04, tol.rel = 1e-04, maxit = 10000,
            adjmaxit = NULL, K = 5, crit.cv = c("loglik", "penloglik", "AIC",
            "BIC"), start = c("warm", "cold"), cores = 1, trace = c("progress",
            "print", "none"))
```

Arguments

- **X** option to provide a nxp data matrix. Each row corresponds to a single observation and each column contains n observations of a single feature/variable.
- **S** option to provide a pxp sample covariance matrix (denominator n). If argument is NULL and X is provided instead then S will be computed automatically.
- **nlam** number of lam tuning parameters for penalty term generated from lam.min.ratio and lam.max (automatically generated). Defaults to 10.
- **lam.min.ratio** smallest lam value provided as a fraction of lam.max. The function will automatically generate nlam tuning parameters from lam.min.ratio*lam.max to lam.max in log10 scale. lam.max is calculated to be the smallest lam such that all off-diagonal entries in Omega are equal to zero (alpha = 1). Defaults to 1e-2.
ADMMsigma

lam option to provide positive tuning parameters for penalty term. This will cause nlam and lam.min.ratio to be disregarded. If a vector of parameters is provided, they should be in increasing order. Defaults to NULL.

alpha elastic net mixing parameter contained in [0, 1], 0 = ridge, 1 = lasso. If a vector of parameters is provided, they should be in increasing order. Defaults to grid of values seq(0, 1, 0.2).

diagonal option to penalize the diagonal elements of the estimated precision matrix (Ω). Defaults to FALSE.

path option to return the regularization path. This option should be used with extreme care if the dimension is large. If set to TRUE, cores must be set to 1 and errors and optimal tuning parameters will be based on the full sample. Defaults to FALSE.

rho initial step size for ADMM algorithm.

mu factor for primal and residual norms in the ADMM algorithm. This will be used to adjust the step size rho after each iteration.

tau.inc factor in which to increase step size rho

tau.dec factor in which to decrease step size rho

crit criterion for convergence (ADMM or loglik). If crit = loglik then iterations will stop when the relative change in log-likelihood is less than tol.abs. Default is ADMM and follows the procedure outlined in Boyd, et al.

tol.abs absolute convergence tolerance. Defaults to 1e-4.

tol.rel relative convergence tolerance. Defaults to 1e-4.

maxit maximum number of iterations. Defaults to 1e4.

adjmaxit adjusted maximum number of iterations. During cross validation this option allows the user to adjust the maximum number of iterations after the first lam tuning parameter has converged (for each alpha). This option is intended to be paired with warm starts and allows for 'one-step' estimators. Defaults to NULL.

K specify the number of folds for cross validation.

crit.cv cross validation criterion (loglik, penloglik, AIC, or BIC). Defaults to loglik.

start specify warm or cold start for cross validation. Default is warm.

cores option to run CV in parallel. Defaults to cores = 1.

trace option to display progress of CV. Choose one of progress to print a progress bar, print to print completed tuning parameters, or none.

Details

For details on the implementation of 'ADMMsigma', see the website https://mgallow.github.io/ADMMsigma/articles/Details.html.

Value

returns class object ADMMsigma which includes:

Call function call.

Iterations number of iterations.
ADMMsigma

Tuning optimal tuning parameters (lam and alpha).
Lambdas grid of lambda values for CV.
Alphas grid of alpha values for CV.
maxit maximum number of iterations.
Omega estimated penalized precision matrix.
Sigma estimated covariance matrix from the penalized precision matrix (inverse of Omega).
Path array containing the solution path. Solutions will be ordered in ascending alpha values for each lambda.
Z final sparse update of estimated penalized precision matrix.
Y final dual update.
rho final step size.
Loglik penalized log-likelihood for Omega
MIN.error minimum average cross validation error (cv.crit) for optimal parameters.
AVG.error average cross validation error (cv.crit) across all folds.
CV.error cross validation errors (cv.crit).

Examples

# generate data from a sparse matrix
# first compute covariance matrix
S = matrix(0.7, nrow = 5, ncol = 5)
for (i in 1:5){
  for (j in 1:5){
    S[i, j] = S[i, j]*abs(i - j)
  }
}

# generate 100 x 5 matrix with rows drawn from iid N_p(0, S)
set.seed(123)
Z = matrix(rnorm(100*5), nrow = 100, ncol = 5)
out = eigen(S, symmetric = TRUE)
S.sqrt = out$vectors %*% diag(out$values^0.5)
S.sqrt = S.sqrt %*% t(out$vectors)
X = Z %*% S.sqrt

# elastic-net type penalty (use CV for optimal lambda and alpha)
ADMMsigma(X)

# ridge penalty (use CV for optimal lambda)
ADMMsigma(X, alpha = 0)

# lasso penalty (lam = 0.1)
ADMMsigma(X, lam = 0.1, alpha = 1)

---

plot.ADMM

Plot ADMM object

Description

Produces a plot for the cross validation errors, if available.

Usage

```r
## S3 method for class 'ADMM'
plot(x, type = c("line", "heatmap"), footnote = TRUE, ...)
```

Arguments

- `x`: class object ADMM.
- `type`: produce either 'heatmap' or 'line' graph
- `footnote`: option to print footnote of optimal values. Defaults to TRUE.
- `...`: additional arguments.
Examples

```r
# generate data from a sparse matrix
# first compute covariance matrix
S = matrix(0.7, nrow = 5, ncol = 5)
for (i in 1:5){
  for (j in 1:5){
    S[i, j] = S[i, j]^abs(i - j)
  }
}

# generate 100 x 5 matrix with rows drawn from iid N_p(0, S)
set.seed(123)
Z = matrix(rnorm(100*5), nrow = 100, ncol = 5)
out = eigen(S, symmetric = TRUE)
S.sqrt = out$vectors %*% diag(out$values^0.5)
S.sqrt = S.sqrt %*% t(out$vectors)
X = Z %*% S.sqrt

# produce line graph for ADMMsigma
plot(ADMMsigma(X), type = 'line')

# produce CV heat map for ADMMsigma
plot(ADMMsigma(X), type = 'heatmap')
```

---

**plot.RIDGE**  
*Plot RIDGE object*

### Description

Produces a heat plot for the cross validation errors, if available.

### Usage

```r
## S3 method for class 'RIDGE'
plot(x, type = c("heatmap", "line"), footnote = TRUE, ...)
```

### Arguments

- `x`  
  class object RIDGE

- `type`  
  produce either 'heatmap' or 'line' graph

- `footnote`  
  option to print footnote of optimal values. Defaults to TRUE.

- `...`  
  additional arguments.
Examples

```r
# generate data from a sparse matrix
# first compute covariance matrix
S = matrix(0.7, nrow = 5, ncol = 5)
for (i in 1:5)
  for (j in 1:5)
    S[i, j] = S[i, j]^abs(i - j)

# generate 100 x 5 matrix with rows drawn from iid N_p(0, S)
set.seed(123)
Z = matrix(rnorm(100*5), nrow = 100, ncol = 5)
out = eigen(S, symmetric = TRUE)
S.sqrt = out$vectors %% diag(out$values^0.5)
S.sqrt = S.sqrt %% t(out$vectors)
X = Z %*% S.sqrt

# produce CV heatmap for RIDGEsigma
plot(RIDGEsigma(X, lam = 10^-seq(-5, 5, 0.5))

# produce line graph for RIDGEsigma
plot(RIDGEsigma(X), type = 'line')
```

RIDGESigma

**Ridge penalized precision matrix estimation**

**Description**

Ridge penalized matrix estimation via closed-form solution. If one is only interested in the ridge penalty, this function will be faster and provide a more precise estimate than using ADMMSigma. Consider the case where \( X_1, \ldots, X_n \) are iid \( N_p(\mu, \Sigma) \) and we are tasked with estimating the precision matrix, denoted \( \Omega \equiv \Sigma^{-1} \). This function solves the following optimization problem:

**Objective:**

\[
\hat{\Omega}_\lambda = \arg \min_{\Omega \in S_p} \left\{ Tr(S\Omega) - \log \det(\Omega) + \frac{\lambda}{2} \|\Omega\|_F^2 \right\}
\]

where \( \lambda > 0 \) and \( \|\cdot\|_F^2 \) is the Frobenius norm.

**Usage**

```
RIDGESigma(X = NULL, S = NULL, lam = 10^-seq(-2, 2, 0.1), path = FALSE,
K = 5, cores = 1, trace = c("none", "progress", "print"))
```

**Arguments**

- **X**
  - option to provide a nxp data matrix. Each row corresponds to a single observation and each column contains n observations of a single feature/variable.

- **S**
  - option to provide a pxp sample covariance matrix (denominator n). If argument is NULL and X is provided instead then S will be computed automatically.
lam positive tuning parameters for ridge penalty. If a vector of parameters is provided, they should be in increasing order. Defaults to grid of values $10^{\text{seq}(-2, 2, 0.1)}$.

path option to return the regularization path. This option should be used with extreme care if the dimension is large. If set to TRUE, cores will be set to 1 and errors and optimal tuning parameters will based on the full sample. Defaults to FALSE.

K specify the number of folds for cross validation.

cores option to run CV in parallel. Defaults to cores = 1.

trace option to display progress of CV. Choose one of progress to print a progress bar, print to print completed tuning parameters, or none.

Value returns class object RIDGEsigma which includes:

Lambda optimal tuning parameter.

Lambdas grid of lambda values for CV.

Omega estimated penalized precision matrix.

Sigma estimated covariance matrix from the penalized precision matrix (inverse of Omega).

Path array containing the solution path. Solutions are ordered dense to sparse.

Gradient gradient of optimization function (penalized gaussian likelihood).

MIN.err error minimum average cross validation error (cv.crit) for optimal parameters.

AVG.err error average cross validation error (cv.crit) across all folds.

CV.err error cross validation errors (cv.crit).
