Package ‘BNSP’

May 8, 2020

Title Bayesian Non- And Semi-Parametric Model Fitting
Version 2.1.4
Date 2020-05-08
Author Georgios Papageorgiou
Maintainer Georgios Papageorgiou <gpapageo@gmail.com>
Description MCMC algorithms & processing functions for: 1. multivariate (and univariate) regression, with nonparametric models for the means, the variances and the correlation matrix, with variable selection, and 2. Dirichlet process mixtures.
Depends R (>= 3.1.0)
Imports coda, ggplot2, plot3D, threejs, gridExtra, cubature, Formula, plyr, mgcv, corrplot, label.switching
LinkingTo cubature
Suggests mvtnorm, np
License GPL (>= 2)
URL http://www.bbk.ac.uk/ems/faculty/papageorgiou/BNSP
NeedsCompilation yes
Repository CRAN

Bayesian non- and semi-parametric model fitting

Description

Markov chain Monte Carlo algorithms for non- and semi-parametric models: 1. spike-slab variable selection in multivariate mean/variance regression models with function `mvrm`, and 2. Dirichlet process mixture models with function `dpmj`.

chol

The Cholesky and modified Cholesky decompositions

Description

Computes the Cholesky factorization and modified Cholesky factorizations of a real symmetric positive-definite square matrix.

Usage

chol(x, mod = TRUE, p = 1, ...)

Arguments

x A symmetric, positive-definite matrix.
mod Defaults to TRUE. With this choice, the function returns the modified Cholesky decomposition. When mod = FALSE, the function returns the usual Cholesky decomposition.
p Relevant only when mod = TRUE. It determines the size of the blocks of the block diagonal matrix.
... other arguments.

Details

The function computes the modified Cholesky decomposition of a real symmetric positive-definite square matrix \( \Sigma \). This is given by

\[ L \Sigma L^\top = D, \]

where \( L \) is a lower tringular matrix with ones on its main diagonal and \( D \) is a block diagonal matrix with block size determined by argument \( p \).

Value

The function returns matrices \( L \) and \( D \).

Examples
```r
correlation <- matrix(c(1.21,0.18,0.13,0.41,0.06,0.23,
                          0.18,0.64,0.10,-0.16,0.23,0.07,
                          0.13,0.10,0.36,-0.10,0.03,0.18,
                          0.41,-0.16,-0.10,1.05,-0.29,-0.08,
                          0.06,0.23,0.03,-0.29,1.71,-0.10,
                          0.23,0.07,0.18,-0.08,-0.10,0.36),6,6)
LD <- chol(correlation)
L <- LD$L
D <- LD$D
round(L,5)
round(D,5)
solve(L) %*% D %*% solve(t(L))

LD <- chol(correlation, p = 2)
L <- LD$L
D <- LD$D
round(L, 5)
round(D, 5)
solve(L) %*% D %*% solve(t(L))
```

clustering

Computes the similarity matrix

Description
Computes the similarity matrix.

Usage
```r
clustering(object, ...)
```

Arguments

object an object of class "mvrm", usually a result of a call to mvrm.

... other arguments.

Details
The function computes the similarity matrix for clustering based on correlations or variables.
Value
Similarity matrix.

mvrm

Examples
#see \code{mvrm} example

continue

Continues the sampler from where it stopped

Description
Allows the user to continue the sampler from the state it stopped in the previous call to mvrm.

Usage
continue(object, sweeps, discard = FALSE, ...)

Arguments

object
An object of class "mvrm", usually a result of a call to mvrm.
sweeps
The number of additional sweeps, maintaining the same thinning interval as specified in the original call to mvrm.
discard
If set to true, the previous samples are discarded.
...
other arguments.

Details
The function allows the sampler to continue from the state it last stopped.

Value
The function returns an object of class mvrm.

dpmj

\textit{Dirichlet process mixtures of joint models}

Description

Fits Dirichlet process mixtures of joint response-covariate models, where the covariates are of mixed type while the discrete responses are represented utilizing continuous latent variables. See ‘Details’ section for a full model description and Papageorgiou (2018) for all technical details.

Usage

\aline{dpmj(formula, Fcdf, data, offset, sampler = "truncated", Xpred, offsetPred, 
StorageDir, ncomp, sweeps, burn, thin = 1, seed, H, Hdf, d, D, 
Alpha.xi, Beta.xi, Alpha.alpha, Beta.alpha, Trunc.alpha, ...)}

Arguments

- \texttt{formula} a formula defining the response and the covariates e.g. \texttt{y ~ x}.
- \texttt{Fcdf} a description of the kernel of the response variable. Currently five options are supported: 1. "poisson", 2. "negative binomial", 3. "generalized poisson", 4. "binomial" and 5. "beta binomial". The first three kernels are used for count data analysis, where the third kernel allows for both over- and under-dispersion relative to the Poisson distribution. The last two kernels are used for binomial data analysis. See ‘Details’ section for some of the kernel details.
- \texttt{data} an optional data frame, list or environment (or object coercible by \texttt{as.data.frame} to a data frame) containing the variables in the model. If not found in ‘data’, the variables are taken from ‘environment(formula)’.
- \texttt{offset} this can be used to specify an a priori known component to be included in the model. This should be ‘NULL’ or a numeric vector of length equal to the sample size. One ‘offset’ term can be included in the formula, and if more are required, their sum should be used.
- \texttt{sampler} the MCMC algorithm to be utilized. The two options are \texttt{sampler = "slice"} which implements a slice sampler (Walker, 2007; Papaspiliopoulos, 2008) and \texttt{sampler = "truncated"} which proceeds by truncating the countable mixture at \texttt{ncomp} components (see argument \texttt{ncomp}).
- \texttt{Xpred} an optional design matrix the rows of which include the values of the covariates \texttt{x} for which the conditional distribution of \texttt{Y|x, D} (where \texttt{D} denotes the data) is calculated. These are treated as ‘new’ covariates i.e. they do not contribute to the likelihood. The matrix shouldn’t include a column of 1’s. NA’s can be included to obtain averaged effects.
offsetPred the offset term associated with the new covariates Xpred. It is of dimension one i.e. the same offset term is used for all rows of Xpred. If Fcdf is one of "poisson" or "negative binomial" or "generalized poisson", then offsetPred is the Poisson offset term. If Fcdf is one of "binomial" or "beta binomial", then offsetPred is the number of Binomial trials. If offsetPred is missing, it is taken to be the mean of offset, rounded to the nearest integer.

StorageDir a directory to store files with the posterior samples of models parameters and other quantities of interest. If a directory is not provided, files are created in the current directory and removed when the sampler completes.

ncomp number of mixture components. It defines where the countable mixture of densities [in (1) below] is truncated. Even if sampler="slice" is chosen, ncomp needs to be specified as it is used in the initialization process.

sweeps total number of posterior samples, including those discarded in burn-in period (see argument burn) and those discarded by the thinning process (see argument thin).

burn length of burn-in period.

thin thinning parameter.

seed optional scale seed for the random generator.

H optional scale matrix of the Wishart-like prior assigned to the restricted covariance matrices \( \Sigma_h \). See ‘Details’ section.

Hdf optional degrees of freedom of the prior Wishart-like prior assigned to the restricted covariance matrices \( \Sigma_h \). See ‘Details’ section.

d optional prior mean of the mean vector \( \mu_h \). See ‘Details’ section.

D optional prior covariance matrix of the mean vector \( \mu_h \). See ‘Details’ section.

Alpha.xi an optional parameter that depends on the specified Fcdf argument.

1. If Fcdf = "poisson", this argument is parameter \( \alpha_\xi \) of the prior of the Poisson rate: \( \xi \sim \text{Gamma}(\alpha_\xi, \beta_\xi) \).

2. If Fcdf = "negative binomial", this argument is a two-dimensional vector that includes parameters \( \alpha_{1\xi} \) and \( \alpha_{2\xi} \) of the priors: \( \xi_1 \sim \text{Gamma}(\alpha_{1\xi}, \beta_{1\xi}) \) and \( \xi_2 \sim \text{Gamma}(\alpha_{2\xi}, \beta_{2\xi}) \), where \( \xi_1 \) and \( \xi_2 \) are the two parameters of the Negative Binomial pmf.

3. If Fcdf = "generalized poisson", this argument is a two-dimensional vector that includes parameters \( \alpha_{1\xi} \) and \( \alpha_{2\xi} \) of the priors: \( \xi_1 \sim \text{Gamma}(\alpha_{1\xi}, \beta_{1\xi}) \) and \( \xi_2 \sim \mathcal{N}(\alpha_{2\xi}, \beta_{2\xi})I[\xi_2 \in R_{\xi_2}] \), where \( \xi_1 \) and \( \xi_2 \) are the two parameters of the Generalized Poisson pmf. Parameter \( \xi_2 \) is restricted in the range \( R_{\xi_2} = (0.05, \infty) \) as it is a dispersion parameter.

4. If Fcdf = "binomial", this argument is parameter \( \alpha_\xi \) of the prior of the Binomial probability: \( \xi \sim \text{Beta}(\alpha_\xi, \beta_\xi) \).

5. If Fcdf = "beta binomial", this argument is a two-dimensional vector that includes parameters \( \alpha_{1\xi} \) and \( \alpha_{2\xi} \) of the priors: \( \xi_1 \sim \text{Gamma}(\alpha_{1\xi}, \beta_{1\xi}) \) and \( \xi_2 \sim \text{Gamma}(\alpha_{2\xi}, \beta_{2\xi}) \), where \( \xi_1 \) and \( \xi_2 \) are the two parameters of the Beta Binomial pmf.

See ‘Details’ section.

Beta.xi an optional parameter that depends on the specified family.
1. If Fcdf = "poisson", this argument is parameter $\beta_{\xi}$ of the prior of the Poisson rate: $\xi \sim \text{Gamma}(\alpha_{\xi}, \beta_{\xi})$.

2. If Fcdf = "negative binomial", this argument is a two-dimensional vector that includes parameters $\beta_{1\xi}$ and $\beta_{2\xi}$ of the priors: $\xi_1 \sim \text{Gamma}(\alpha_{1\xi}, \beta_{1\xi})$ and $\xi_2 \sim \text{Gamma}(\alpha_{2\xi}, \beta_{2\xi})$, where $\xi_1$ and $\xi_2$ are the two parameters of the Negative Binomial pmf.

3. If Fcdf = "generalized poisson", this argument is a two-dimensional vector that includes parameters $\beta_{1\xi}$ and $\beta_{2\xi}$ of the priors: $\xi_1 \sim \text{Gamma}(\alpha_{1\xi}, \beta_{1\xi})$ and $\xi_2 \sim \text{Normal}(\alpha_{2\xi}, \beta_{2\xi})|\xi_2 \in R_{\xi_2}]$, where $\xi_1$ and $\xi_2$ are the two parameters of the Generalized Poisson pmf. Parameter $\xi_2$ is restricted in the range $R_{\xi_2} = (0.05, \infty)$ as it is a dispersion parameter. Note that $\beta_{2\xi}$ is a standard deviation.

4. If Fcdf = "binomial", this argument is parameter $\beta_{\xi}$ of the prior of the Binomial probability: $\xi \sim \text{Beta}(\alpha_{\xi}, \beta_{\xi})$.

5. If Fcdf = "beta binomial", this argument is a two-dimensional vector that includes parameters $\beta_{1\xi}$ and $\beta_{2\xi}$ of the priors: $\xi_1 \sim \text{Gamma}(\alpha_{1\xi}, \beta_{1\xi})$ and $\xi_2 \sim \text{Gamma}(\alpha_{2\xi}, \beta_{2\xi})$, where $\xi_1$ and $\xi_2$ are the two parameters of the Beta Binomial pmf.

See ‘Details’ section.

\texttt{Alpha.alpha} optional shape parameter $\alpha_{\alpha}$ of the Gamma prior assigned to the concentration parameter $\alpha$. See ‘Details’ section.

\texttt{Beta.alpha} optional rate parameter $\beta_{\alpha}$ of the Gamma prior assigned to concentration parameter $\alpha$. See ‘Details’ section.

\texttt{Trunc.alpha} optional truncation point $c_{\alpha}$ of the Gamma prior assigned to concentration parameter $\alpha$. See ‘Details’ section.

... Other options that will be ignored.

\section*{Details}

Function \texttt{dpmj} returns samples from the posterior distributions of the parameters of the model:

$$f(y_i, x_i) = \sum_{h=1}^{\infty} \pi_h f(y_i, x_i | \theta_h),$$

(1)

where $y_i$ is a univariate discrete response, $x_i$ is a $p$-dimensional vector of mixed type covariates, and $\pi_h, h \geq 1$, are obtained according to Sethuraman’s (1994) stick-breaking construction: $\pi_1 = \nu_1$, and for $l \geq 2, \pi_l = \nu_l \prod_{j=1}^{l-1} (1 - \nu_j)$, where $\nu_k$ are iid samples $v_k \sim \text{Beta}(1, \alpha), k \geq 1$.

Let $Z$ denote a discrete variable (response or covariate). It is represented as discretized version of a continuous latent variable $Z^*$. Observed discrete $Z$ and continuous latent variable $Z^*$ are connected by:

$$z = q \iff c_{q-1} < z^* < c_q, q = 0, 1, 2, \ldots,$$

where the cut-points are obtained as: $c_{-1} = -\infty$, while for $q \geq 0, c_q = c_q(\lambda) = \Phi^{-1}\{F(q; \lambda)\}$. Here $\Phi(\cdot)$ is the cumulative distribution function (cdf) of a standard normal variable and $F()$ denotes an appropriate cdf. Further, latent variables are assumed to independently follow a $N(0, 1)$ distribution, where the mean and variance are restricted to be zero and one as they are non-identifiable by the data. Choices for $F()$ are described next.
For counts, three options are supported. First, $F(\cdot; \lambda_i)$ can be specified as the cdf of a Poisson($H_i \xi_h$) variable. Here $\lambda_i = (\xi_h, H_i)^T$, $\xi_h$ denotes the Poisson rate associated with cluster $h$, and $H_i$ the offset term associated with sampling unit $i$. Second, $F(\cdot; \lambda_i)$ can be specified as the negative binomial cdf, where $\lambda_i = (\xi_{ih}, \xi_{2h}, H_i)^T$. This option allows for overdispersion within each cluster relative to the Poisson distribution. Third, $F(\cdot; \lambda_i)$ can be specified as the Generalized Poisson cdf, where, again, $\lambda_i = (\xi_{ih}, \xi_{2h}, H_i)^T$. This option allows for both over- and under-dispersion within each cluster.

For Binomial data, two options are supported. First, $F(\cdot; \lambda_i)$ may be taken to be the cdf of a Binomial($H_i, \xi_h$) variable, where $\xi_h$ denotes the success probability of cluster $h$ and $H_i$ the number of trials associated with sampling unit $i$. Second, $F(\cdot; \lambda_i)$ may be specified to be the beta-binomial cdf, where $\lambda = (\xi_{ih}, \xi_{2h}, H_i)^T$.

The special case of Binomial data is treated as

$$Z = 0 \iff z^* < 0, z^* \sim N(\mu^*_z, 1).$$

Details on all kernels are provided in the two tables below. The first table provides the probability mass functions and the mean in the presence of an offset term (which may be taken to be one). The column 'Sample' indicates for which parameters the routine provides posterior samples. The second table provides information on the assumed priors along with the default values of the parameters of the prior distributions and it also indicates the function arguments that allow the user to alter these.

Let $z_i = (y_i, x_i^T)^T$ denote the joint vector of observed continuous and discrete variables and $z_i^*$ the corresponding vector of continuous observed and latent variables. With $\theta_h$ denoting model parameters associated with the $h$th cluster, the joint density $f(z_i|\theta_h)$ takes the form

$$f(z_i|\theta_h) = \int_{R(y)} \int_{R(x_a)} N_q(z_i^*; \mu^*_h, \Sigma^*_h) dx_a^* dy^*,$$
where
\[
\begin{align*}
\mu_h^* &= \begin{pmatrix} 0 \\ \mu_h \end{pmatrix}, \\
\Sigma_h^* &= \begin{bmatrix} C_h & \nu_h^T \\ \nu_h & \Sigma_h \end{bmatrix},
\end{align*}
\]
where \(C_h\) is the covariance matrix of the latent continuous variables and it has diagonal elements equal to one i.e. it is a correlation matrix.

In addition to the priors defined in the table above, we specify the following:

1. The restricted covariance matrix \(\Sigma_h^*\) is assigned a prior distribution that is based on the Wishart distribution with degrees of freedom set by default to dimension of matrix plus two and diagonal scale matrix, with the sub-matrix that corresponds to discrete variables taken to be the identity matrix and with sub-matrix that corresponds to continuous variables having entries equal to 1/8 of the square of the observed data range. Default values can be changed using arguments \(H\) and \(Hdf\).

2. The prior on \(\mu_h\), the non-zero part of \(\mu_h^*\), is taken to be multivariate normal \(\mu_h \sim N(d, D)\). The mean \(d\) is taken to be equal to the center of the dataset. The covariance matrix \(D\) is taken to be diagonal. Its elements that correspond to continuous variables are set equal to 1/8 of the square of the observed range while the elements that correspond to binary variables are set equal to 5. Arguments \(Mu.mu\) and \(Sigma.mu\) allow the user to change the default values.

3. The concentration parameter \(\alpha\) is assigned a Gamma \((\alpha, \beta)\) prior over the range \((c_\alpha, \infty)\), that is, \(f(\alpha) \propto \alpha^{\alpha-1} \exp\{-\alpha \beta\} I[\alpha > c_\alpha]\), where \(I[\cdot]\) is the indicator function. The default values are \(\alpha = 2.0\), \(\beta = 5.0\), and \(c_\alpha = 0.25\). Users can alter the default using using arguments \(Alpha.alpha\), \(Beta.alpha\) and \(Turnc.alpha\).

Value

Function \(dpmj\) returns the following:

- **call**
  the matched call.

- **seed**
  the seed that was used (in case replication of the results is needed).

- **meanReg**
  if \(Xpred\) is specified, the function returns the posterior mean of the conditional expectation of the response \(y\) given each new covariate \(x\).

- **medianReg**
  if \(Xpred\) is specified, the function returns the posterior mean of the conditional 50% quantile of the response \(y\) given each new covariate \(x\).

- **q1Reg**
  if \(Xpred\) is specified, the function returns the posterior mean of the conditional 25% quantile of the response \(y\) given each new covariate \(x\).

- **q3Reg**
  if \(Xpred\) is specified, the function returns the posterior mean of the conditional 75% quantile of the response \(y\) given each new covariate \(x\).

- **modeReg**
  if \(Xpred\) is specified, the function returns the posterior mean of the conditional mode of the response \(y\) given each new covariate \(x\).

- **denReg**
  if \(Xpred\) is specified, the function returns the posterior mean conditional density of the response \(y\) given each new covariate \(x\). Results are presented in a matrix the rows of which correspond to the different \(x\)s.

- **denVar**
  if \(Xpred\) is specified, the function returns the posterior variance of the conditional density of the response \(y\) given each new covariate \(x\). Results are presented in a matrix the rows of which correspond to the different \(x\)s.
Further, function dpmj creates files where the posterior samples are written. These files are (with all file names preceded by ‘BNSP’):

alpha.txt  this file contains samples from the posterior of the concentration parameters $\alpha$. The file is arranged in (sweeps-burn)/thin lines and one column, each line including one posterior sample.

compAlloc.txt  this file contains the allocations to clusters obtained during posterior sampling. It consists of (sweeps-burn)/thin lines, that represent the posterior samples, and $n$ columns, that represent the sampling units. Clusters are represented by integers ranging from 0 to ncomp-1.

MeanReg.txt  this file contains the conditional means of the response $y$ given covariates $x$ obtained during posterior sampling. The rows represent the (sweeps-burn)/thin posterior samples. The columns represent the various covariate values $x$ for which the means are obtained.

MedianReg.txt  this file contains the 50% conditional quantile of the response $y$ given covariates $x$ obtained during posterior sampling. The rows represent the (sweeps-burn)/thin posterior samples. The columns represent the various covariate values $x$ for which the medians are obtained.

muh.txt  this file contains samples from the posteriors of the $p$-dimensional mean vectors $\mu_h, h = 1, 2, \ldots, ncomp$. The file is arranged in ((sweeps-burn)/thin)*ncomp lines and $p$ columns. In more detail, sweeps create ncomp lines representing samples $\mu_h^{(sw)}, h = 1, \ldots, ncomp$, where superscript $sw$ represents a particular sweep. The elements of $\mu_h^{(sw)}$ are written in the columns of the file.

nmembers.txt  this file contains (sweeps-burn)/thin lines and ncomp columns, where the lines represent posterior samples while the columns represent the components or clusters. The entries represent the number of sampling units allocated to each component.

Q05Reg.txt  this file contains the 5% conditional quantile of the response $y$ given covariates $x$ obtained during posterior sampling. The rows represent the (sweeps-burn)/thin posterior samples. The columns represent the various covariate values $x$ for which the quantiles are obtained.

Q10Reg.txt  as above, for the 10% conditional quantile.

Q15Reg.txt  as above, for the 15% conditional quantile.

Q20Reg.txt  as above, for the 20% conditional quantile.

Q25Reg.txt  as above, for the 25% conditional quantile.

Q75Reg.txt  as above, for the 75% conditional quantile.

Q80Reg.txt  as above, for the 80% conditional quantile.

Q85Reg.txt  as above, for the 85% conditional quantile.

Q90Reg.txt  as above, for the 90% conditional quantile.

Q95Reg.txt  as above, for the 95% conditional quantile.

Sigmah.txt  this file contains samples from the posteriors of the $q \times q$ restricted covariance matrices $\Sigma_h, h = 1, 2, \ldots, ncomp$. The file is arranged in ((sweeps-burn)/thin)*ncomp lines and $q^2$ columns. In more detail, sweeps create ncomp lines representing samples $\Sigma_h^{(sw)}, h = 1, \ldots, ncomp$, where superscript $sw$ represents a particular sweep. The elements of $\Sigma_h^{(sw)}$ are written in the columns of the file.
xih.txt this file contains samples from the posteriors of parameters $\xi_h, h = 1, 2, \ldots, n_{\text{comp}}$. The file is arranged in $((\text{sweeps}-\text{burn})/\text{thin}) \times n_{\text{comp}}$ lines and one or two columns, depending on the number of parameters in the selected Fcdf. Sweeps write in the file $n_{\text{comp}}$ lines representing samples $\xi_h^{(s_w)}, h = 1, \ldots, n_{\text{comp}}$, where superscript $s_w$ represents a particular sweep.

Updated.txt this file contains $\text{sweeps}-\text{burn}/\text{thin}$ lines with the number of components updated at each iteration of the sampler (relevant for slice sampling).

**histCorr**

*Creates plots of correlation matrices*

**Description**

This function plots the posterior distribution of the elements of correlation matrices.

**Usage**

```r
histCorr(x, term = "R", plotOptions = list(), ...)
```

**Arguments**

- `x`:
  - an object of class `mvrm`, as generated by function `mvrm`.

- `term`:
  - Admits two possible values: "R" to plot samples from the posterior of the correlation matrix $R$, and "muR" to plot samples from the posterior of the means $\mu_R$.

- `plotOptions`:
  - ggplot type options.

- `...`:
  - other arguments.

**Details**

Use this function to visualize the elements of a correlation matrix.

**Value**

Posterior distributions of elements of correlation matrices.

**Author(s)**

Georgios Papageorgiou <gpapageo@gmail.com>

**Examples**

```r
# see \code{mvrm} example
```
mvrm

Bayesian semiparametric analysis of multivariate continuous responses, with variable selection

Description

Implements an MCMC algorithm for posterior sampling based on a semiparametric model for continuous multivariate responses and additive models for the mean and variance functions. The model utilizes spike-slab priors for variable selection and regularization. See ‘Details’ section for a full description of the model.

Usage

mvrm(formula, data = list(), sweeps, burn = 0, thin = 1, seed, StorageDir,
c.betaPrior = "IG(0.5, 0.5 * n * p)", pi.muPrior = "Beta(1, 1)",
c.alphaPrior = "IG(1.1, 1.1)", sigmaPrior = "HN(2)", pi.sigmaPrior = "Beta(1, 1)",
mu.RPrior = "N(0, 1)", sigma.RPrior = "HN(1)", corr.Model = c("common", nClust = 1),
DP.concPrior = "Gamma(5, 2)", tuneAlpha, tuneSigma2, tuneCb, tuneCa, tuneR,
tuneSigma2R, tau, FT = 1, ...)

Arguments

formula a formula defining the responses and the covariates in the mean and variance models e.g. y1 | y2 ~ x | z or for smooth effects y1 | y2 ~ sm(x) | sm(z). The package uses the extended formula notation, where the responses are defined on the left of ~ and the mean and variance models on the right.
data a data frame.
sweeps total number of posterior samples, including those discarded in burn-in period (see argument burn) and those discarded by the thinning process (see argument thin).
burn length of burn-in period.
thin thinning parameter.
seed optional seed for the random generator.
StorageDir a required directory to store files with the posterior samples of models parameters.
c.betaPrior The inverse Gamma prior of $c_\beta$. The default is $"IG(0.5, 0.5*n*p)\)\)"$, that is, an inverse Gamma with parameters $1/2$ and $np/2$, where $n$ is the number of sampling units and $p$ is the length of the response vector.
pi.muPrior The Beta prior of $\pi_\mu$. The default is "Beta(1,1)". It can be of dimension 1, of dimension $K$ (the number of effects that enter the mean model), or of dimension $pK$
c.alphaPrior The inverse Gamma prior of $c_\alpha$. The default is "IG(1.1,1.1)". Half-normal priors for $\sqrt{c_\alpha}$ are also available, declared using "HN(a)", where "a" is a positive number. It can be of dimension 1 or $p$ (the length of the multivariate response).
sigmaPrior  The prior of $\sigma$. The default is "HN(2)", a half-normal prior for $\sigma$ with variance equal to two, $\sigma \sim N(0, 2)I[\sigma > 0]$. Inverse Gamma priors for $\sigma^2$ are also available, declared using "IG(a,b)". It can be of dimension 1 or $p$ (the length of the multivariate response).

pi.sigmaPrior  The Beta prior of $\pi_\sigma$. The default is "Beta(1,1)". It can be of dimension 1, of dimension $Q$ (the number of effects that enter the variance model), or of dimension $pQ$

mu.RPrior  The normal prior for $\mu_R$. The default is the standard normal distribution.

sigma.RPrior  The half normal prior for $\sigma_R$. The default is the half normal distribution with variance one.

corr.Model  Specifies the model for the correlation matrix $R$. The three choices supported are "common", that specifies a common correlations model, "groupC", that specifies a grouped correlations model, and "groupV", that specifies a grouped variables model. When the model chosen is either "groupC" or "groupV", the upper limit on the number of clusters can also be specified, using corr.Model = c("groupC", nClust = d) or corr.Model = c("groupV", nClust = p). If the number of clusters is left unspecified, for the "groupV" model, it is taken to be $p$, the number of responses. For the "groupC" model, it is taken to be $d = p(p-1)/2$, the number of free elements in the correlation matrix.

DP.concPrior  The Gamma prior for the Dirichlet process concentration parameter.

tuneAlpha  Starting value of the tuning parameter for sampling regression coefficients of the variance model $\alpha$. Defaults at 5.

tuneSigma2  Starting value of the tuning parameter for sampling variances $\sigma^2_j$. Defaults at 1.

tuneCb  Starting value of the tuning parameter for sampling $c_\beta$. Defaults at 10.

tuneCa  Starting value of the tuning parameter for sampling $c_\alpha$. Defaults at 1.

tuneR  Starting value of the tuning parameter for sampling correlation matrices. Defaults at $100(p+2)$.

tuneSigma2R  Starting value of the tuning parameter for sampling $\sigma^2_R$. Defaults at 1.

tau  The $\tau$ of the shadow prior. Defaults at 0.01.

FT  Binary indicator. If set equal to 1, the Fisher’s z transform of the correlations is modelled, otherwise if set equal to 0, the untransformed correlations are modelled.

...  Other options that will be ignored.

Details

Function mmvrm returns samples from the posterior distributions of the parameters of a regression model with normally distributed multivariate responses and mean and variance functions modeled in terms of covariates. For instance, in the presence of two responses $(y_1, y_2)$ and two covariates in the mean model $(u_1, u_2)$ and two in the variance model $(w_1, w_2)$, we may choose to fit

$$
\mu_u = \beta_0 + \beta_1 u_1 + f_\mu(u_2),
$$

$$
\log(\sigma^2_w) = \alpha_0 + \alpha_1 w_1 + f_\sigma(w_2),
$$
parametrically modelling the effects of $u_1$ and $w_1$ and non-parametrically modelling the effects of $u_2$ and $w_2$. Smooth functions, such as $f_\mu$ and $f_\sigma$, are represented by basis function expansion,

\[ f_\mu(w_2) = \sum_j \beta_j \phi_j(w_2), \]
\[ f_\sigma(w_2) = \sum_j \alpha_j \phi_j(w_2), \]

where $\phi$ are the basis functions and $\beta$ and $\alpha$ are regression coefficients.

The variance model can equivalently be expressed as

\[ \sigma^2_W = \exp(\alpha_0) \exp(\alpha_1 w_1 + f_\sigma(w_2)) = \sigma^2 \exp(\alpha_1 w_1 + f_\sigma(w_2)), \]

where $\sigma^2 = \exp(\alpha_0)$. This is the parameterization that we adopt in this implementation.

Positive prior probability that the regression coefficients in the mean model are exactly zero is achieved by defining binary variables $\gamma$ that take value $\gamma = 1$ if the associated coefficient $\beta \neq 0$ and $\gamma = 0$ if $\beta = 0$. Indicators $\delta$ that take value $\delta = 1$ if the associated coefficient $\alpha \neq 0$ and $\delta = 0$ if $\alpha = 0$ for the variance function are defined analogously. We note that all coefficients in the mean and variance functions are subject to selection except the intercepts, $\beta_0$ and $\alpha_0$.

Prior specification:
For the vector of non-zero regression coefficients $\beta_\gamma$ we specify a g-prior

\[ \beta_\gamma|c_\beta, \sigma^2, \gamma, \delta \sim N(0, c_\beta \sigma^2 (\tilde{X}_\gamma \tilde{X}_\gamma)^{-1}). \]

where $\tilde{X}$ is a scaled version of design matrix $X$ of the mean model.

For the vector of non-zero regression coefficients $\alpha_\delta$ we specify a normal prior

\[ \alpha_\delta|c_\alpha \sim N(0, c_\alpha I). \]

Independent priors are specified for the indicators variables $\gamma$ and $\delta$ as $P(\gamma = 1|\pi_\mu) = \pi_\mu$ and $P(\delta = 1|\pi_\sigma) = \pi_\sigma$. Further, Beta priors are specified for $\pi_\mu$ and $\pi_\sigma$

\[ \pi_\mu \sim Beta(c_\mu, d_\mu), \pi_\sigma \sim Beta(c_\sigma, d_\sigma). \]

We note that blocks of regression coefficients associated with distinct covariate effects have their own probability of selection ($\pi_\mu$ or $\pi_\sigma$) and this probability has its own prior distribution.

Further, we specify inverse Gamma priors for $c_\beta$ and $c_\alpha$

\[ c_\beta \sim IG(a_\beta, b_\beta), c_\alpha \sim IG(a_\alpha, b_\alpha). \]

For $\sigma^2$ we consider inverse Gamma and half-normal priors

\[ \sigma^2 \sim IG(a_\sigma, b_\sigma), |\sigma| \sim N(0, \phi_\sigma^2). \]

Lastly, for the elements of the correlation matrix, we specify normal distributions with mean $\mu_R$ and variance $\sigma^2_R$, with the priors on these two parameters being normal and half-normal, respectively. This is the common correlations model. Further, the grouped correlations model can be specified. It considers a mixture of normal distributions for the means $\mu_R$. The grouped correlations model can also be specified. It clusters the variables instead of the correlations.
Value

Function mvrm returns the following:

call the matched call.
formula model formula.
seed the seed that was used (in case replication of the results is needed).
data the dataset
X the mean model design matrix.
Z the variance model design matrix.
LG the length of the vector of indicators $\gamma$.
LD the length of the vector of indicators $\delta$.
mcpars the MCMC parameters: length of burn in period, total number of samples, thinning period.
nSamples total number of posterior samples
DIR the storage directory

Further, function mvrm creates files where the posterior samples are written. These files are (with all file names preceded by ‘BNSP’):

alpha.txt contains samples from the posterior of vector $\alpha$. Rows represent posterior samples and columns represent the regression coefficient, and they are in the same order as the columns of design matrix $Z$.
beta.txt contains samples from the posterior of vector $\beta$. Rows represent posterior samples and columns represent the regression coefficients, and they are in the same order as the columns of design matrix $X$.
gamma.txt contains samples from the posterior of the vector of the indicators $\gamma$. Rows represent posterior samples and columns represent the indicator variables, and they are in the same order as the columns of design matrix $X$.
delta.txt contains samples from the posterior of the vector of the indicators $\delta$. Rows represent posterior samples and columns represent the indicator variables, and they are in the same order as the columns of design matrix $Z$.
sigma2.txt contains samples from the posterior of the error variance $\sigma^2$ of each response.
cbeta.txt contains samples from the posterior of $c_\beta$.
calpha.txt contains samples from the posterior of $c_\alpha$.
R.txt contains samples from the posterior of the correlation matrix $R$.
theta.txt contains samples from the posterior of $\theta$ of the shadow prior (probably not needed).
muR.txt contains samples from the posterior of $\mu_R$.
sigma2R.txt contains samples from the posterior of $\sigma^2_R$.
deviance.txt contains the deviance, minus twice the log likelihood evaluated at the sampled values of the parameters.

In addition to the above, for models that cluster the correlations we have
mvrm

**compAlloc.txt** The cluster at which the correlations were allocated, $\lambda_{kl}$. These are integers from zero to the specified number of clusters minus one.

**nmembers.txt** The numbers of correlations assigned to each cluster.

**DPconc.txt** Contains samples from the posterior of the Dirichlet process concentration parameter.

In addition to the above, for models that cluster the variables we have

**compAllocV.txt** The cluster at which the variables were allocated, $\lambda_{k}$. These are integers from zero to the specified number of clusters minus one.

**nmembersV.txt** The numbers of variables assigned to each cluster.

mvrn2mcmc

Convert posterior samples from function mvrm into an object of class ‘mcmc’

Description
Reads in files where the posterior samples were written and creates an object of class ‘mcmc’ so that functions like summary and plot from package coda can be used

Usage
mvrn2mcmc(mvrmObj, labels)

Arguments
mvrmObj An object of class ‘mvrm’ as created by a call to function mvrm.
labels The labels of the files to be read in. These can be one or more of: “alpha”, “beta”, “gamma”, “delta”, “sigma2”, “cbeta”, “calpha”, “R”, “muR”, “sigma2R”, “nmembers”, “nmembersV”, “compAlloc”, “compAllocV”, and “DPconc” and they correspond to the parameters of the model that a call to functions mvrm fits. In addition, “deviance” can be read in. If left unspecified, all files are read in.

Value
An object of class ‘mcmc’ that holds the samples from the posterior of the selected parameter.

Author(s)
Georgios Papageorgiou <gpapageo@gmail.com>

plot.mvrm

Creates plots of terms in the mean and/or variance models

Description

This function plots estimated terms that appear in the mean and variance models.

Usage

## S3 method for class 'mvrm'
plot(x, model, term, response, response2, intercept = TRUE, grid = 30, 
     centre = mean, quantiles = c(0.1, 0.9), contour = TRUE, static = TRUE, 
     centreEffects = FALSE, plotOptions = list(), nrow, ask = FALSE, 
     plotEmptyCluster = FALSE, ...)

Arguments

x an object of class ‘mvrm’ as generated by function mvrm.
model one of "mean", "stdev", or "both", specifying which model to be visualized.
term the term in the selected model to be plotted.
response integer number denoting the response variable to be plotted (in case there is more than one).
response2 only relevant for multivariate longitudinal data.
intercept specifies if an intercept should be included in the calculations.
grid the length of the grid on which the term will be evaluated.
centre a description of how the centre of the posterior should be measured. Usually mean or median.
quantiles the quantiles to be used when plotting credible regions. Plots without credible intervals may be obtained by setting this argument to NULL.
contour relevant for 3D plots only. If contour=TRUE then plot.mvrm creates contour plots. contour=FALSE is allowed only for creating one plot at a time. The plot can be static or dynamic. See argument 'static'.
static relevant for 3D plots only. If static=TRUE then plot.mvrm calls function ribbon3D from package plot3D to create the plot. If static=FALSE then plot.mvrm calls function scatterplot3js from package threejs to create the plot.
centreEffects if TRUE then the effects in the mean functions are centred around zero over the range of the predictor while the effects in the variance function are scaled around one.
plotOptions for plots of univariate smooth terms or for plots of bivariate smooth terms where one of the two covariates is discrete, this is a list of plot elements to give to ggplot. For smooths of bivariate continuous covariates, this is a list of plot elements to give to ribbon3D (if static=FALSE) or to scatterplot3js (if static=TRUE).
plotCorr

nrow: the number of rows in the figure with the plots.
ask: if set to TRUE, plots will be displayed one at a time.
plotEmptyCluster: if set to TRUE, plots of empty clusters will be displayed. Relevant for multivariate longitudinal datasets.
...
other arguments.

Details
Use this function to obtain predictions.

Value
Predictions along with credible/prediction intervals

Author(s)
Georgios Papageorgiou <gpapageo@gmail.com>

Examples
#see \code{mvrm} example

plotCorr

\textit{Creates plots of the correlation matrices}

Description
This function plots the posterior mean and credible intervals of the elements of correlation matrices.

Usage
plotCorr(x, term = "R", centre = mean, quantiles = c(0.1, 0.9), ...)

Arguments
x: an object of class ‘mmvrm’ as generated by function mmvrm.
term: R or muR,
centre: a description of how the centre of the posterior should be measured. Usually mean or median.
quantiles: the quantiles to be used when plotting credible regions. Plots without credible intervals may be obtained by setting this argument to NULL.
...: other arguments.
**Details**

Use this function to visualize the elements of a correlation matrix.

**Value**

Posterior means and credible intervals of elements of correlation matrices.

**Author(s)**

Georgios Papageorgiou <gpapageo@gmail.com>

**See Also**

mvrm

**Examples**

# see \code{mvrm} example

---

**Description**

Provides predictions and posterior credible/prediction intervals for given feature vectors.

**Usage**

```r
## S3 method for class 'mvrm'
predict(object, newdata, interval = c("none", "credible", "prediction"),
        level = 0.95, nSamples = 100, ...)
```

**Arguments**

- `object`: an object of class "mvrm", usually a result of a call to `mvrm`.
- `newdata`: data frame of feature vectors to obtain predictions for. If `newdata` is missing, the function will use the feature vectors in the data frame used to fit the `mvrm` object.
- `interval`: type of interval calculation.
- `level`: tolerance level.
- `nSamples`: number of samples to obtain from the posterior predictive distribution (for each sweep of the MCMC). Only relevant for "prediction intervals".
- `...`: other arguments.
Details

The function returns predictions of new responses or the means of the responses for given feature vectors. Predictions for new responses or the means of new responses are the same. However, the two differ in the associated level of uncertainty: response predictions are associated with wider (prediction) intervals than mean response predictions. To obtain prediction intervals (for new responses) the function samples from the normal distributions with means and variances as sampled during the MCMC run.

Value

Predictions for given covariate/feature vectors.

**Details**

The most relevant arguments for BNSP users are the list of variables..., knots, absorb.cons, bs, and by.

**Value**

A design matrix that specifies a smooth term in a model.

**Author(s)**

Georgios Papageorgiou <gpapageo@gmail.com>

---

**Description**

Just a simulated dataset to illustrate the model. The success probability and the covariate have a non-linear relationship.

**Usage**

data(simD)

**Format**

A data frame with 300 independent observations. Three numerical vectors contain information on

- Y number of successes.
- E number of trials.
- X explanatory variable.
**sm**  
*Smooth terms in mvrm formulae*

**Description**
Function used to define smooth effects in the mean and variance formulae of function `mvrm`. The function is used internally to construct the design matrices.

**Usage**
```r
sm(..., k = 10, knots = NULL, bs = "rd")
```

**Arguments**
- `...`: one or two covariates that the smooth term is a function of. If two covariates are used, they may be both continuous or one continuous and one discrete. Discrete variables should be defined as `factor` in the `data` argument of the calling `mvrm` function.
- `k`: the number of knots to be utilized in the basis function expansion.
- `knots`: the knots to be utilized in the basis function expansion.
- `bs`: a two letter character indicating the basis functions to be used. Currently, the options are "rd" that specifies radial basis functions and is available for univariate and bivariate smooths, and "pl" that specifies thin plate splines that are available for univariate smooths.

**Details**
Use this function within calls to function `mvrm` to specify smooth terms in the mean and/or variance function of the regression model.

Univariate radial basis functions with `q` basis functions or `q - 1` knots are defined by

\[
B_1 = \{ \phi_1(u) = u, \phi_2(u) = |u - \xi_1|^2 \log (|u - \xi_1|^2), \ldots, \phi_q(u) = |u - \xi_{q-1}|^2 \log (|u - \xi_{q-1}|^2) \},
\]

where `|u|` denotes the Euclidean norm of `u` and `\xi_1, \ldots, \xi_{q-1}` are the knots that are chosen as the quantiles of the observed values of explanatory variable `u`, with `\xi_1 = \min(u_i), \xi_{q-1} = \max(u_i)` and the remaining knots chosen as equally spaced quantiles between `\xi_1` and `\xi_{q-1}`.

Thin plate splines are defined by

\[
B_2 = \{ \phi_1(u) = u, \phi_2(u) = (u - \xi_1)_+, \ldots, \phi_q(u) = (u - \xi_{q})_+ \},
\]

where `(a)_+ = \max(a, 0)`.

Radial basis functions for bivariate smooths are defined by

\[
B_3 = \{ u_1, u_2, \phi_3(u) = |u - \xi_1|^2 \log (|u - \xi_1|^2), \ldots, \phi_q(u) = |u - \xi_{q-1}|^2 \log (|u - \xi_{q-1}|^2) \}.
\]

**Value**
Specifies the design matrices of an `mvrm` call.
**summary.mvrm**

**Examples**

```r
#see \code{mvrm} example
```

---

**summary.mvrm**

**Summary of an mvrm fit**

**Description**

Provides basic information from an mvrm fit.

**Usage**

```r
## S3 method for class 'mvrm'
summary(object, nModels = 5, digits = 5, printTuning = FALSE, ...)
```

**Arguments**

- `object` an object of class "mvrm", usually a result of a call to mvrm.
- `nModels` integer number of models with the highest posterior probability to be displayed.
- `digits` the number of significant digits to use when printing.
- `printTuning` if set to TRUE, the starting and finishig values of the tuning parameters are displayed.
- `...` other arguments.

**Details**

Use this function to summarize mvrm fits.

**Value**

The functions provides a detailed description of the specified model and priors. In addition, the function provides information about the Markov chain ran (length, burn-in, thinning) and the folder where the files with posterior samples are stored. Lastly, the function provides the mean posterior and null deviance and the mean/variance models visited most often during posterior sampling.

- `m` see mgcv::te
- `d` see mgcv::te
The most relevant arguments for BNSP users are the list of variables ... knots, absorb.cons, bs, and by.

A design matrix that specifies a smooth term in a model.

Georgios Papageorgiou <gpapageo@gmail.com>

Provides interface between mgcv::ti and BNSP. ti(...) calls mgcv::smoothCon(mgcv::ti(...),...)

... a list of variables. See mgcv::ti

data see mgcv::smoothCon

knots see mgcv::knots

absorb.cons see mgcv::smoothCon

scale.penalty see mgcv::smoothCon

n see mgcv::smoothCon
dataX see mgcv::smoothCon
null.space.penalty see mgcv::smoothCon
sparse.cons see mgcv::smoothCon
diagonal.penalty see mgcv::smoothCon
apply.by see mgcv::smoothCon
modCon see mgcv::smoothCon
k see mgcv::ti
bs see mgcv::ti
m see mgcv::ti
d see mgcv::ti
by see mgcv::ti
fx see mgcv::ti
np see mgcv::ti
xt see mgcv::ti
id see mgcv::ti
sp see mgcv::ti
mc see mgcv::ti
pc see mgcv::ti

Details
The most relevant arguments for BNSP users are the list of variables ..., knots, absorb.cons, bs, and by.

Value
A design matrix that specifies a smooth term in a model.
