Package 'CAvariants'

January 14, 2019

Type Package

Title Correspondence Analysis Variants

Version 4.0

Date 2019-01-14

Author Rosaria Lombardo and Eric J Beh

Maintainer Rosaria Lombardo <rosaria.lombardo@unicampania.it>

Description Provides six variants of two-way correspondence analysis (ca): simple ca, singly ordered ca, doubly ordered ca, non symmetrical ca, singly ordered non symmetrical ca, and doubly ordered non symmetrical ca.

Depends R (> 3.0.1), methods, tools, ggplot2, gridExtra, ggrepel, rgl

Date/Publication 2019-01-14 15:40:05 UTC

R topics documented:

`angle` *Angle*

Description

The internal **R** function `angle` is used to draw ellipses around points in a graphical display.

Details

This function is used in two other functions that are `caellipse` and `nscaellipse`.

References

Macdonald PDM 2002 Drawing an ellipse in Splus or R. Available at www.math.mcmaster.ca/peter/s4m03/s4m03_0102/ellipse.html (accessed August 18, 2016).

`asbestos` *Selikoff's data, a two-way contingency table.*

Description

The data set consists of 4 rows and 5 columns. The rows represent the degree of severity of asbestosis and the columns are concerned with the time of exposure to asbestos in years of the workers

Usage

```
data(asbestos)
```

Format

The format is:
row names [1:4] "None" "grade1" "grade2" "grade3"
col names [1:5] "0-9" "10-19" "20-29" "30-39" "40+"

References

Beh EJ and Lombardo R 2014 Correspondence Analysis: Theory, Practice and New Strategies. Wiley.
Selikoff IJ 1981 Household risks with inorganic fibers. Bulletin of the New York Academy of Medicine, 57, 947 – 961.

Examples

```
asbestos <-structure(c(310, 36, 0, 0, 212, 158, 9, 0, 21, 35, 17, 4, 25,
102, 49, 18, 7, 35, 51, 28), .Dim = 4:5, .Dimnames = list(c("none",
"grade1", "grade2", "grade3"), c("0-9", "10-19", "20-29", "30-39",
"40+")))
dim(asbestos)
dimnames(asbestos)
```

---

cabasic *Classical two-way correspondence analysis*

Description

This function is used in the main function `CAvariants` when the input parameter is `catype = "CA"`. It performs the singular value decomposition of Pearson's ratio and computes principal axes, coordinates, the weights of rows and columns, the total inertia (equal to Pearson's index) and the rank of the matrix.

Usage

```
cabasic(Xtable)
```

Arguments

`Xtable`	The two-way contingency table.

Note

This function belongs to the `R` object class called `cabasicresults`.

Author(s)

Rosaria Lombardo and Eric J. Beh

Examples

```
data(asbestos)
cabasic(asbestos)
```

`caellipse` *Algebraic elliptical confidence regions for symmetrical variants of correspondence analysis*

Description

It produces elliptical confidence regions when symmetrical or ordered symmetrical correspondence analysis is performed. This function allows the analyst to superimpose confidence ellipses onto a graphical display when the input parameter `catype` of the main function `CAvariants` is set to `"CA"`, `"SOCA"` or `"DOCA"`. It is called internally from the main plot function `plot.CAvariants`. It uses the function `ellipse`.

Usage

```
caellipse(Xtable, a1 = 1, a2 = 2, alpha = 0.05, cols = c(2, 4), M = 2, cex = 0.8,
cex.lab = 0.8, mar = c(5, 4, 4, 2) + 0.1, prop = 0.8, Imass, Jmass, a, b, g, f, dmu,
inertiapc, plottype = "biplot", biptype = "row", pos = 2, arrow = TRUE, length = 0,
ell = TRUE)
```

Arguments

`Xtable`	The two-way contingency table.
`a1`	The axis number of the horizontal axis.
`a2`	The axis number of the vertical axis.
`alpha`	The confidence level of the elliptical regions. By default, `alpha = 0.05`.
`cols`	The graphical parameter for setting the colours of the points in the graphical displays.
`M`	The number of axes used for constructing the confidence ellypses. By default, `M = 2`. Its maximum value is equal to the rank of the data matrix.
`cex`	The parameter for setting the size of the character labels for the points in a graphical display. By default, `cex = 0.8`.

cex.lab	The parameter for setting the size of character labels of axes in graphical displays. By default, cex.lab = 0.8.
mar	The parameter for setting the size of the plotting area. By default, mar = c(5, 4, 4, 2) + 0.1.
prop	The scaling parameter for specifying the limits of the plotting area. By default, prop = 1.
Imass	The weight matrix of the row variable.
Jmass	The weight matrix of the column variable.
a	The row standard coordinates or, in case of the ordered variants of CA, the row standard polynomial coordinates.
b	The column standard coordinates or, in case of the ordered variants of CA, the column standard polynomial coordinates.
f	The row principal coordinates (scaled by a constant, by default scaleplot = 1).
g	The column principal coordinates (scaled by a constant, by default scaleplot = 1).
dmu	The squared singular values, or principal inertia, of each axis.
inertiapc	The percentage of explained inertia along each of the axes.
pos	The parameter that specifies the position of label of each point in the graphical display. By default, pos = 2.
plottype	The type of graphical display to be constructed. By default, plottype = "biplot"; the alternative is plottype = "classic".
biptype	The parameter for specifying the type of biplot. By default, biptype = "row".
arrow	The parameter used for diplaying the arrows in a biplot. By default, arrow = TRUE.
length	The parameter used for setting the length of the arrow end in a biplot. By default, length = 0.
ell	The logical parameter used for displaying the confidence ellipses. By default, ell = TRUE.

Details

The output values of this function.

Value

eccentricity	The eccentricity of the ellipses. This is the distance between the centre of the ellipse and its two foci, which can be thought of as a measure of how much the conic section deviates from being circular (when the region is perfectly circular, eccentricity is zero).
HL Axis 1	Value of the semi-major axis length for each row and column point.
HL Axis 2	Value of the semi-minor axis length for each row and column point.
Area	Area of the ellipse for each row and column point.
pvalcol	Approximate p-value for each of the row and column points.

Note

This function is called from the main plot function plot.CAvariants and is executed when ell = TRUE.

Author(s)

Rosaria Lombardo and Eric J Beh

`caellipseprint` *Numerical characteristics of elliptical confidence regions in variants of symmetrical correspondence analysis*

Description

It produces the numerical characteristics of the elliptical confidence regions when symmetrical or ordered symmetrical correspondence analysis is performed. This function allows the analyst to superimpose confidence ellipses onto a graphical display when `catype = "CA"`, `catype = "SOCA"` or `catype = "DOCA"`. It is called internally from the main plot function `print.CAvariants`. It uses the function `ellipse`.

Usage

```
caellipseprint(Xtable, a1 = 1, a2 = 2, alpha = 0.05,  M = 2,
Imass, Jmass, a, b, g, f, dmu, inertiapc)
```

Arguments

`Xtable`	The two-way contingency table.
`a1`	The first axis number.
`a2`	The second axis number.
`alpha`	The confidence level of the elliptical regions. By default, `alpha = 0.05`.
`M`	The number of axes used for constructing the ellypses. By default, `M = 2`. Its maximum value is equal to the rank of the data matrix.
`Imass`	The weight matrix of the row variable.
`Jmass`	The weight matrix of the column variable.
`a`	The row standard coordinates or, in case of the ordered variants of CA, the row standard polynomial coordinates.

b	The column standard coordinates or, in case of the ordered variants of CA, the column standard polynomial coordinates.
f	The row principal coordinates (scaled by a constant, by default `scaleplot = 1`).
g	The column principal coordinates (scaled by a constant, by default `scaleplot = 1`).
dmu	The squared singular values or inertia of each axis.
inertiapc	The percentage of explained inertia.

Details

The output values of this function.

Value

eccentricity	Value of ellipse eccentricity. This is the distance between the ellipse center and either of its two foci, which can be thought of as a measure of how much the conic section deviates from being circular (when it is equal to zero then the region becomes circular).
HL Axis 1	Value of ellipse semi-axis 1 for each row and column points.
HL Axis 2	Value of ellipse semi-axis 2 for each row and column points.
Area	Ellipse area for each row and column points.
pvalcol	P-value for each row and column points.

---

caplot3d *Three dimensional correspondence plot*

Description

This function is used in the plot function `plot.CAvariants` when the logical parameter is `plot3d = TRUE`. It produces a 3-dimensional visualization of the association.

Usage

```
caplot3d(f, g, percIn, size=10, adj=c(0,0.5) ,prop=1)
```

Arguments

f	The row principal or standard coordinates.
g	The column principal or standard coordinates.
percIn	The percentage of the total inertia explained inertia by each principal axis.
size	The size of the plotting area. By default, `size = 10`.
adj	One or two values in the interval [0, 1] that specifies the x (and optionally y) position of the label categories. By default, `adj = c(0, 0.5)`.
prop	The scaling parameter for specifying the limits of the plotting area. By default, `prop = 1`.

Note

This function depends on the R library `rgl`.

CAvariants *Six variants of correspondence analysis*

Description

It performs
1) simple correspondence analysis
2) doubly ordered correspondence analysis
3) singly ordered correspondence analysis
4) non symmetrical correspondence analysis
5) doubly ordered non symmetrical correspondence analysis
6) singly ordered non symmetrical correspondence analysis

Usage

```
CAvariants(Xtable, mj = NULL, mi = NULL, firstaxis = 1, lastaxis = 2,
catype = "CA", ellcomp = TRUE, M = min(nrow(Xtable), ncol(Xtable)) - 1, alpha = 0.05)
```

Arguments

Xtable	The two-way contingency table.
mi	The assigned ordered scores for the row categories. By default, mi = NULL, which gives consecutive integer valued (natural) scores.
mj	The assigned ordered scores for the column categories, By default, mj = NULL, which gives consecutive integer valued (natural) scores.
firstaxis	The horizontal polynomial, or principal, axis. By default firstaxis = 1.
lastaxis	The vertical polynomial, or principal, axis. By default lastaxis = 2.
catype	The input parameter for specifying what variant of correspondence analysis is to be performed. By default, catype = "CA". Other possible values are: catype = "SOCA", catype = "DOCA", catype = "NSCA", catype = "SONSCA", catype = "DONSCA".
ellcomp	This input parameter ensures that the characteristics of the algebraic confidence ellipses are computed and stored. When ellcomp = TRUE (which is by default), the output includes the characteristics of the ellipses. The eccentricity of the confidence ellipses is summarised by the quantity eccentricity, which is the distance between the center and either of its two foci, and can be thought of as a measure of how much the conic section deviates from being circular (when the regions are perfectly circular than the eccentricity is zero). The semi-major axis length of the ellipse for each row and column point is given by HL Axis 1 while HL Axis 2 gives the semi-minor axis length of the points. The area of the ellipse for each row and column category is given by Area while the p-value of each category is given by P-value.
M	The number of axes used for determining the structure of the elliptical confidence regions. By default, M = min(nrow(Xtable), ncol(Xtable)) - 1, i.e. the rank of the data matrix.
alpha	The level of significance for the elliptical regions. By default, alpha = 0.05.

Value

Description of the output returned

Xtable	The two-way contingency table.
rows	The number of rows of the two-way contingency table.
cols	The number of columns of the two-way contingency table.
r	The rank of the two-way contingency table.
rowlabels	The labels of the row variable.
collabels	The labels of the column variable.
Rprinccoord	The row principal coordinates. When the input parameter catype is "DOCA", "SOCA", "DONSCA" or "SONSCA", they are row principal polynomial coordinates.
Cprinccoord	The column principal coordinates. When the input parameter catype is "DOCA", "SOCA", "DONSCA" or "SONSCA", they are column principal polynomial coordinates.

Rstdcoord	The row standard coordinates. When the input parameter catype is "DOCA", "SOCA", "DONSCA" or "SONSCA", they are row standard polynomial coordinates.
Cstdcoord	The column standard coordinates. When the input parameter catype is "DOCA", "SOCA", "DONSCA" or "SONSCA", they are column standard polynomial coordinates.
tauden	The denominator of the Goodman-Kruskal tau index is given when the input parameter catype is "NSCA", "SONSCA", or "DONSCA". Otherwise it is NULL.
tau	The index of Goodman and Kruskal is given when the input parameter catype is "NSCA", "SONSCA", or "DONSCA". Otherwise it is NULL.
inertiasum	The total inertia of the analysis based on Pearson's chi-squared when catype is "CA", "DOCA" or "SOCA", or based on the Goodman-Kruskal tau when catype is "NSCA", "DONSCA" or "SONSCA" (numerator of the Goodman-Kruskal tau index).
inertias	The inertia in absolute value and percentage, in the row space for each principal or polynomial axis.
inertias2	The inertia in absolute value and percentage, in the column space for each principal or polynomial axis. When catype is "CA" or "NSCA" the associated inertia in the row and column spaces are the same for each principal axis.
comps	The polynomial components of inertia when the variables are ordered.
catype	The type of correspondence analysis chosen by the analyst. By default, catype = "ca".
mj	The ordered scores of the column variable. When mj = NULL, the natural scores are used (i = 1,...,cols).
mi	The ordered scores of the row variable. When mi = NULL, the natural scores are used (i = 1,...,rows).
pcc	The weighted centered column profile matrix.
Jmass	The weight matrix of the column variable.
Imass	The weight matrix of the row variable.
Trend	The inner product, Inner product, of the biplot coordinates (for the two axes defined by firstaxis = 1 and lastaxis = 2)
Z	The generalised correlation matrix when catype = "SOCA", catype = "DOCA" , catype = "SONSCA", catype = "DONSCA", but when catype = "CA", or catype = "NSCA", it gives again the inner product matrix of biplot coordinates.
ellcomp	This parameter specifies whether the characteristics of the confidence ellipses (eccentricity, semi-axis, area, p-values) are to be computed. By default, ellcomp = TRUE.
resellprint	When ellcomp = TRUE, the output includes the numerical characteristics resellprint of the confidence ellipses, the eccentricity of the confidence ellipses, risell$eccentricity, for each row and column point, the summary results, resellprint$row.summ and resellprint$col.summ, contain the semi-major axis length of the ellipse, HL Axis 1, the semi-minor axis length for the ellipse, HL Axis 2, the area of the ellipse, Area and the p-value, P-value.
M	The number of axes M considered in determining the structure of the elliptical confidence regions. By default, M = min(nrow(Xtable), ncol(Xtable)) - 1, i.e. the rank of the data matrix.

Note

This function recalls internally many other functions, depending on the setting of the input parameter catype, it recalls one of the six functions which does a variant of correspondence analysis. After performing a variant of correspondence analysis, it gives the output object necessary for printing and plotting the results. These two important functions are print.CAvariants and plot.CAvariants.

Examples

```
data(asbestos)
CAvariants(asbestos, catype = "CA", firstaxis = 1, lastaxis = 2)
CAvariants(asbestos, catype = "DOCA", mi = c(1:nrow(asbestos)), mj =c(4.5,14.5,24.5,34.5,44.5),
firstaxis = 1,lastaxis = 2, ellcomp = TRUE, M = min(nrow(asbestos), ncol(asbestos)) - 1)
CAvariants(asbestos, catype = "DONSCA", firstaxis = 1, lastaxis = 2)
data(shopdataM)
CAvariants(shopdataM, catype = "NSCA", firstaxis = 1, lastaxis = 3)
CAvariants(shopdataM, catype = "SONSCA", firstaxis = 1, lastaxis = 2)
CAvariants(shopdataM, catype = "SOCA", firstaxis = 1, lastaxis = 2)
```

---

compsonetable.exe *Polynomial component of inertia in column space*

Description

This function allows the analyst to compute the contribution that the polynomial components make to the inertia (Pearson's chi-squared statistic or the Goodman-Kruskal tau index). The ordered variable should be the column variable that is transformed by polynomials. The polynomial components are the column polynomial components. The given input matrix is the Z matrix of generalised correlations from the hybrid decomposition. It is called by CAvariants when catype = "SOCA" or catype = "SONSCA".

Usage

```
compsonetable.exe(Z)
```

Arguments

Z	The matrix of generalised correlations between the polynomial and principal axes.

Value

The value returned is the matrix

comps	The matrix of the column polynomial component of inertia.

Note

This function belongs to the class called cacorporateplus.

---

compstable.exe *Polynomial component of inertia for the row and column spaces*

Description

This function allows the analyst to compute the contribution of the polynomial components to the inertia (Pearson's chi-squared statistic or the Goodman-Kruskal tau index). The ordered variable should be both the row and column variables that are transformed by the polynomials. The polynomial components are the row and column polynomial components. The given input matrix is the Z matrix of generalised correlations from the bivariate moment decomposition. It is called by CAvariants when catype = "DOCA" or catype = "DONSCA".

Usage

```
compstable.exe(Z)
```

Arguments

Z	The matrix of generalised correlations between the polynomial axes.

Value

The value returned is the matrix

comps	The matrix of the polynomial components of the inertia.

---

docabasic *Doubly, or two-way, ordered correspondence analysis: for two ordered variables*

Description

This function is used by the main function `CAvariants` when the input parameter is `catype = "DOCA"`. It performs the bivariate moment decomposition of the Pearson ratio, computes polynomial axes, coordinates, weights of rows and columns, total inertia (based on Pearson's chi-squared statistic), the rank of the matrix. It also decomposes the inertia into row and column polynomial components.

Usage

```
docabasic(Xtable, mi, mj)
```

Arguments

Xtable	The two-way contingency table.
mi	The set of ordered row scores. By default, `mi = c(1:nrow(Xtable))` (natural scores).
mj	The set of ordered column scores. By default, `mj = c(1:ncol(Xtable))` (natural scores).

Author(s)

Rosaria Lombardo and Eric J. Beh

References

Beh EJ and Lombardo R 2014 Correspondence Analysis: Theory, Practice and New Strategies. Wiley.

Examples

```
data(asbestos)
mi <- c(1,2,3,4) #natural scores for rows
mj <- c(4.5,14.5,24.5,34.5,44.5) #midpoints for columns
docabasic(asbestos, mi, mj)
```

`donscabasic` *Doubly, or two-way ordered, non symmetrical correspondence analysis: for two ordered variables*

Description

This function is used in the main function `CAvariants` when the input parameter is `catype = "DONSCA"`. It performs the bivariate moment decomposition of the numerator of the Goodman-Kruskal tau index for a contingency table consisting of two ordered variables. It computes the polynomial axes, coordinates, weights of the rows and columns, total inertia (equal to the numerator of the tau index) and the rank of the matrix. It also decomposes the inertia into row and column polynomial components.

Usage

```
donscabasic(Xtable, mi, mj)
```

Arguments

`Xtable`	The two-way contingency table.
`mi`	The set of ordered row scores. By default, `mi = c(1:nrow(Xtable))` (natural scores).
`mj`	The set of ordered column scores. By default, `mj = c(1:ncol(Xtable))` (natural scores).

Author(s)

Rosaria Lombardo and Eric J. Beh

Examples

```
data(asbestos)
mi <- c(1, 2, 3, 4) # natural scores for the rows
mj <- c(4.5, 14.5, 24.5, 34.5, 44.5) #midpoints for the columns
donscabasic(asbestos, mi, mj)
```

---

ellipse *Ellipse*

Description

This function is called internally from the graphical functions `caellipse` and `nscaellipse`. It constructs the algebraic confidence ellipses.

Arguments

`hlaxa`	The length of the horizontal ellipse semi-axis.
`hlaxb`	The length of the vertical ellipse semi-axis.
`xc`	The coordinate of the generic point on the horizontal axis.
`yc`	The coordinate of the generic point on the vertical axis.
`col`	The color of ellipses.

Note

This function is called from the secondary graphical function `caellipse` or `nscaellipse`, which is called from the main plot function `plot.CAvariants`. It can be executed for all variants of correspondence analysis.

Author(s)

Rosaria Lombardo and Eric J Beh

References

`emerson.poly` *Orthogonal polynomials*

Description

This function is called from the functions `docabasic, socabasic, sonscabasic` and `donscabasic`. It computes the orthogonal polynomials for the ordered categorical variables. The number of the polynomials is equal to the number of categories for that variable less one. The function computes the polynomial transformation of the ordered categorical variable.

Usage

```
emerson.poly(mj, pj)
```

Arguments

`mj`	The ordered scores of the ordered variable. By default, `mj = NULL`, the natural scores (1, 2, ...) are computed.
`pj`	The marginal relative frequencies of the ordered variable.

Value

Describe the value returned

`B`	the matrix of the orthogonal polynomials with the trivial polynomial removed.

Note

Note that the sum of the marginal relative frequencies of the ordered variables must be one.

Examples

```
emerson.poly(c(1,2,3,4,5), as.vector(c(.1,.2,.3,.2,.2)))
```

nscabasic *Two-way non symmetrical correspondence analysis*

Description

This function is used in the main function `CAvariants` when the input parameter is `catype = "NSCA"`. It calculates the singular value decomposition of the numerator of the Goodman-Kruskal tau index (index of predictability), computes principal axes, coordinates, weights of the rows and columns, total inertia (numerator of the tau index) and the rank of the matrix.

Usage

```
nscabasic(Xtable)
```

Arguments

`Xtable`	The two-way contingency table.

data(asbestos)
nscabasic(asbestos)
```

nscaellipse *Algebraic elliptical confidence regions for non-symmetrical variants of correspondence analysis*

Description

This function produces elliptical confidence regions when non-symmetrical or ordered non-symmetrical correspondence analysis is performed. It superimposes the confidence ellipses onto the graphical displays, when `catype = "NSCA"`, `catype = "SONSCA"` or `catype = "DONSCA"`. It is called from the main plot function `plot.CAvariants` and uses the function `ellipse`.

Usage

```
nscaellipse(Xtable, a1 = 1, a2 = 2, alpha = 0.05, cols = c(2, 4),
M = 2, cex = 0.8, cex.lab = 0.8, mar = c(5, 4, 4, 2) + 0.1, prop = 0.8,  Imass, Jmass,
a, b, f, g, dmu, tauden, inertiapc, plottype = "biplot",
biptype = "row", pos = 2, arrow = TRUE, length = 0,  ell = TRUE)
```

Arguments

Xtable	The two-way contingency table.
a1	The axis number of the horizontal axis.
a2	The axis number of the vertical axis.
alpha	The confidence level of the elliptical regions. By default, alpha = 0.05.
cols	The graphical parameter for setting the colours of the points in the graphical displays.
M	The number of axes used for constructing the confidence ellypses. By default, M = 2. Its maximum value is equal to the rank of the data matrix.
cex	The parameter for setting the size of the character labels for the points in a graphical display. By default, cex = 0.8.
cex.lab	The parameter for setting the size of the character labels of axes in graphical displays. By default, cex.lab = 0.8.
mar	The parameter for setting the size of the plotting area. By default, mar = c(5, 4, 4, 2) + 0.1.
prop	The scaling parameter for specifying the limits of the plotting area. By default, prop = 1.
Imass	The weight matrix of the row variable.
Jmass	The weight matrix of the column variable.
a	The row standard coordinates or, in case of the ordered variants of NSCA, the row standard polynomial coordinates.
b	The column standard coordinates or, in case of the ordered variants of NSCA, the column standard polynomial coordinates.
f	The row principal coordinates (scaled by a constant, by default scaleplot = 1).
g	The column principal coordinates (scaled by a constant, by default scaleplot = 1).
dmu	The squared singular values, or principal inertia, of each axis.
tauden	The denominator of the tau index.
inertiapc	The percentage of explained inertia along each of the axes.
plottype	The type of graphical display to be constructed. By default, plottype = "biplot"; the alternative is plottype = "classic".
biptype	The parameter for specifying the type of biplot. By default, biptype = "row".
pos	The parameter that specifies the position of label of each point in the graphical display. By default, pos = 2.
arrow	The parameter for diplaying the arrows in a biplot. By default, arrow = TRUE.
length	The parameter for setting the length of the arrow end in a biplot. By default, length = 0.
ell	The logical parameter used for displaying the confidence ellipses. By default, ell = TRUE.

Details

The output values of this function

Value

eccentricity	The eccentricity of the ellipses. This is the distance between the centre of the ellipse and its two foci, which can be thought of as a measure of how much the conic section deviates from being circular (when the region is perfectly circular, eccentricity is zero).
HL Axis 1	Value of the semi-major axis length for each row and column point.
HL Axis 2	Value of the semi-minor axis length for each row and column point.
Area	Area of the ellipse for each row and column point.
pvalcol	Approximate p-value for each of the row and column points.

Note

This function is called from the main plot function `plot.CAvariants` and is executed when `catype = "NSCA"`, `catype = "SONSCA"` or `catype = "DONSCA"`, only if `ell = TRUE`.

nscaellipseprint *Numerical characteristics of elliptical confidence regions in variants of non symmetrical correspondence analysis*

Description

This function produces numerical characteristics of elliptical confidence regions when non symmetrical or ordered non symmetrical correspondence analysis is performed. It superimposes the confidence ellipses on to the graphical displays, when `catype = "NSCA"`, `catype = "SONSCA"` or `catype = "DONSCA"`. It is called from the main plot function `print.CAvariants` and uses the function `ellipse`.

Usage

```
nscaellipseprint(Xtable, a1 = 1, a2 = 2, alpha = 0.05, M = 2,
Imass, Jmass, a, b, f, g, dmu, tauden, inertiapc)
```

Arguments

Xtable	The two-way contingency table.
a1	The dimension reflected along the horizontal axis.
a2	The dimension reflected along the vertical axis.
alpha	The confidence level of the elliptical regions. By default, alpha = 0.05.
M	The number of axes used when drawing ellypse. By default, M = 2. Its maximum value is equal to the rank of the data matrix.
Imass	The weight matrix of the row variable.
Jmass	The weight matrix of the column variable.
a	The row principal or polynomial axes.
b	The column principal or polynomial axes.
f	The row coordinates.
g	The column coordinates.
dmu	The squared singular values or inertia of each axis.
tauden	The denominator of tau index.
inertiapc	The percentage of explained inertia.

Details

The output values of this function

Value

eccentricity	Value of ellipse eccentricity. This is the distance between the ellipse center and either of its two foci, which can be thought of as a measure of how much the conic section deviates from being circular (when it is equal to zero then the region becomes circular).
HL Axis 1	Value of ellipse semi-axis 1 for each row and column points.
HL Axis 2	Value of ellipse semi-axis 2 for each row and column points.
Area	Ellipse area for each row and column points.
pvalcol	P-value for each row and column points.

plot.CAvariants *Main plot function*

Description

This function produces the graphical display for the selected variant of correspondence analysis. When `catype = "CA"` `catype = "NSCA"` and `plottype = "classic"`, the function produces a plot of the principal coordinates for the row and column categories.
When `plottype = "biplot"`, it produces a biplot graphical display, or a polynomial biplot in case of ordered variables. For an ordered analysis only the polynomial biplots are constructed. In particular, for the singly ordered variants only the row isometric polynomial biplot is appropriate. When the parameter `catype` defines an ordered variant of CA, the input parameter `plottype` should be equal to `plottype = "biplot"`. If `biptype = "row"`, it will produce a row isometric polynomial biplot.

Usage

```
## S3 method for class 'CAvariants'
plot(x, firstaxis = 1, lastaxis = 2, cex = 0.8,
cex.lab = 0.8, prop = 1,  plottype = "biplot", biptype = "row",
scaleplot = 1, posleg = "topleft", pos = 2, ell = FALSE, M = x$M,
alpha = 0.05, plot3d = FALSE, size = 5, adj = c(0,0.5),...)
```

Arguments

`x`	The name of the output object used with the main function `CAvariants`.
`firstaxis`	The horizontal polynomial, or principal, axis. By default, `firstaxis = 1`.
`lastaxis`	The vertical polynomial, or principal, axis. By default, `lastaxis = 2`.
`cex`	The parameter for setting the size of the character labels for the points in a graphical display. By default, `cex = 0.8`.
`cex.lab`	The parameter for setting the size of the character labels of axes in graphical displays. By default, `cex.lab = 0.8`.
`prop`	The scaling parameter for specifying the limits of the plotting area. By default, `prop = 1`.
`plottype`	The type of graphical display required (either a correspondence plot or a biplot). The type of graphical display to be constructed. By default, `plottype = "biplot"`; the alternative is `plottype = "classic"`.
`biptype`	The parameter for specifying the type of biplot. By default, `biptype = "row"`. One may specify a row-isometric biplot (`biptype = "row"`) or a column-isometric biplot (`biptype = "column"`). This feature is available for the nominal symmetrical and non-symmetrical correspondence analyses. By default, a row-isometric biplot, `biptype = "row"`, is produced.
`scaleplot`	The parameter for scaling the biplot coordinates. See Gower et al. (2011), section 2.3.1, or page 135 of Beh and Lombardo (2014). By default, `scaleplot = 1`.

posleg	The position of the legend when portraying trends of the categories for ordered variants of correspondence analysis. By default, posleg = "topleft".
pos	The parameter that specifies the position of label of each point in the graphical display. By default, pos = 2.
ell	The logical parameter which specifies whether algebraic confidence ellipses are to be included in the plot or not. Setting the input parameter to ell = TRUE will assess the statistical significance of each category to the association between the variables. By default, ell = FALSE.
M	The number of axes considered in determining the structure of the elliptical confidence regions. By default, M = min(nrow(Xtable), ncol(Xtable)) - 1, i.e. the rank of the data matrix.
alpha	The confidence level of the elliptical regions. By default, alpha = 0.05.
plot3d	The logical parameter specifies whether a 3D plot is to be included in the output or not. By default, plot3d = FALSE.
size	The size of the plotting area. By default, size = 5.
adj	One or two values in the interval [0, 1] that specifies the x (and optionally y) position of the label categories. By default, adj = c(0, 0.5).
...	Further arguments passed to, or from, other functions.

Details

It produces either a classical or biplot graphical display. Further, when catype = "DOCA", catype = "SOCA", catype = "DONSCA" or catype = "SONSCA", the trends of the row and column variables (after the reconstruction of column profiles by the polynomials) is portrayed.
For classical biplot displays, it superimposes the algebraic confidence ellipses. It uses the secondary plot function caellipse (or nscaellipse) for the symmetrical (or non symmetrical) CA variants.

Note

For the classical plots, row and column principal coordinates are plotted. For biplots, one set of coordinates is the standard coordinates and the other is the principal coordinates. When an ordered variant of correspondence analysis is performed, the biplot is constructed where one set of coordinates consists of the standard polynomial coordinates and the other one is the principal polynomial coordinates.

Examples

```
data(asbestos)
resasbestos<-CAvariants(asbestos, catype = "CA", firstaxis = 1, lastaxis = 2)
plot(resasbestos, plottype = "classic", plot3d = TRUE)
plot(resasbestos, plottype = "biplot", biptype = "column", ell = TRUE)
plot(resasbestos, plottype = "classic", ell = TRUE)
```

`print.CAvariants` *Main printing function for numerical summaries*

Description

This function prints the numerical output for any of the six variants of correspondence analysis called by `catype`.
The input parameter is the name of the output of the main function `CAvariants`.

Usage

```
## S3 method for class 'CAvariants'
print(x, printdims = 2, ellprint = TRUE, alpha = 0.05, digits = 3,...)
```

Arguments

`x`	The name of the output object from the main function `CAvariants`.
`printdims`	The number of dimensions that are used for summarising the numerical output of the analysis. By default, `printdims = 2`. the maximum number is equal to the rank of the table.
`ellprint`	The logical parameter specifies whether the numerical characteristics of the confidence ellipses (eccentricity, semi-axis, area, p-values) are to be displayed. By default, `ellprint = TRUE`.
`alpha`	The confidence level of the elliptical regions. By default, `alpha = 0.05`.
`digits`	The number of decimal places used for displaying the numerical summaries of the analysis. By default, `digits = 3`.
`...`	Further arguments passed to, or from, other functions.

Details

This function uses another function (called `printwithaxes`) for specifying the number of columns of a matrix to print.

Value

The output returned depends on the type of correspondence analysis that is performed

`Xtable` The two-way contingency table.

`Row weights: Imass`
The row weight matrix. These weights depend on the type of analysis that is performed.

`Column weights: Jmass`
The column weight matrix. These weights are equal to the column marginal relative frequencies for all types of analysis performed.

`Total inertia` The total inertia of the analysis performed. For example, for variants of non symmetrical correspondence analysis, the output produced includes the numerator of the Goodman-Kruskal tau index, its C-statistic and p-value.

`Inertias` The inertia values, their percentage contribution to the total inertia and the cumulative percent inertias for the row and column variables.

`Generalised correlation matrix`
The matrix of generalised correlations when performing an ordered correspondence analysis, `catype` must be `"DOCA"`, `"DONSCA"`, `"SOCA"` or `"SONSCA"`.

`Row principal coordinates`
The row principal coordinates when `catype = "CA"` or `catype = "NSCA"`.

`Column principal coordinates`
The column principal coordinates when `catype = "CA"` or `catype = "NSCA"`.

`Row standard coordinates`
The row standard coordinates when `catype = "CA"` or `catype = "NSCA"`.

`Column standard coordinates`
The column standard coordinates when `catype = "CA"` or `catype = "NSCA"`.

`Row principal polynomial coordinates`
The row principal polynomial coordinates when performing an ordered correspondence analysis.

`Column principal polynomial coordinates`
The column principal coordinates when performing a doubly ordered correspondence analysis.

`Row standard polynomial coordinates`
The row standard polynomial coordinates, when performing an ordered variant of correspondence analysis.

`Column standard polynomial coordinates`
The column standard polynomial coordinates, when performing an ordered variant of correspondence analysis.

`Row distances from the origin of the plot`
The squared Euclidean distance of the row categories from the origin of the plot.

`Column distances from the origin of the plot`
The squared Euclidean distance of the column categories from the origin of the plot.

`Polynomial components`
: The polynomial components of the total inertia and their p-values. The total inertia of the column space is partitioned to identify polynomial components. when `catype = "SOCA"` or `catype = "SONSCA"`. When `catype = "DOCA"` or `catype = "DONSCA"`, the total inertia of both the row and column space is partitioned to give the polynomial components.

`Inner product`
: The inner product of the biplot coordinates for the two-dimensional plot.

`ellprint`
: The logical parameter used for displaying the numerical characteristics of confidence ellipses. By default, `ell = TRUE`.

Examples

```
data(asbestos)
resasbestos <- CAvariants(asbestos, catype = "DOCA", firstaxis = 1, lastaxis = 2)
print(resasbestos)
```

---

printwithaxes *Secondary printing function*

Description

The function is called from the main print function `print.CAvariants`. It adds the names to objects.

Usage

```
printwithaxes(x, thenames,digits=3)
```

Arguments

`x`
: A matrix.

`thenames`
: A character vector of the same length as `x`.

`digits`
: The number of decimal places used for displaying the numerical summaries of the analysis. By default, `digits = 3`.

shopdataM *Two-way contingency table of Dutch shoplifting (1977-1978)*

Description

This two-way contingency table summarises, in part, the results of a survey of the Dutch Central Bureau of Statistics (Isra\'els, 1987). The table considers a sample of 20819 men who were suspected of shoplifting in stores of the Netherlands between 1977 and 1978.

Usage

```
data(shopdataM)
```

Format

The format is:
row names [1:13] "clothing" "accessories" "tobacco" "stationary" ...
col names [1:9] "M12<" "M13" "M16" "M19" ...

dim(shopdataM)
```

`socabasic` *Singly, or one-way, ordered correspondence analysis: for an ordered column variable*

Description

This function is used by the main function `CAvariants` when the input parameter is `catype = "SOCA"`. It performs the hybrid decomposition of Pearson's ratios and computes the principal axes for the rows and polynomial axes for the columns. It also gives the coordinates, row and column weights, total inertia (based on Pearson's chi-squared statistic) and the rank of the matrix. It decomposes the inertia in terms of the column polynomial components.

Usage

```
socabasic(Xtable, mj)
```

Arguments

`Xtable`	The two-way contingency table.
`mj`	The set of ordered column scores. By default, `mj = c(1:ncol(Xtable))` (natural scores).

Author(s)

Rosaria Lombardo and Eric J. Beh

References

Examples

```
data(asbestos)
mj <- c(1, 2, 3, 4, 5)
socabasic(asbestos, mj)
```

sonscabasic *Singly, or one-way, ordered non symmetrical correspondence analysis: for an ordered column predictor variable*

Description

This function is used by the main function CAvariants when the input parameter is catype = "SONSCA". It performs the hybrid decomposition of the numerator of the Goodman-Kruskal tau index and implies an ordered (column) variable. It calculates the principal axes for the rows and polynomial axes for the columns, coordinates. It also calculates the row and column weights, inertia (based on the numerator of the tau index) and the rank of the matrix. It decomposes the inertia into column polynomial components.

Usage

```
sonscabasic(Xtable, mj)
```

Arguments

Xtable	The two-way contingency table.
mj	The set of ordered column scores. By default, mj = c(1:ncol(Xtable)) (natural scores).

Author(s)

Rosaria Lombardo and Eric J. Beh

mj<-c(1, 2, 3, 4, 5)
sonscabasic(asbestos, mj)
```

summary.CAvariants *Summary of numerical results from CA variants*

Description

This function prints a numerical summary of the results from any of the six variants of correspondence analysis. The input parameter is the name of the output of the main function CAvariants.

Usage

```
## S3 method for class 'CAvariants'
summary(object, printdims, digits, ...)
```

Arguments

object	The output of the main function CAvariants.
printdims	The number of dimensions that are used for summarising the numerical output of the analysis. By default, printdims = 2. the maximum number is equal to the rank of the table.
digits	The number of decimal places used for displaying the numerical summaries of the analysis. By default, digits = 3.
...	Further arguments passed to, or from, other functions.

Value

The value of output returned depends on the type of correspondence analysis that is performed.

Inertias	The inertia values, their percentage contribution to the total inertia and the cumulative percent inertias for the row and column variables.
Generalised correlation matrix	The matrix of generalised correlations when performing an ordered correspondence analysis, catype = "DOCA", catype = "DONSCA", catype = "SOCA" or catype = "SONSCA".
Row principal coordinates	The row principal coordinates when catype = "CA", or catype = "NSCA".
Column principal coordinates	The column principal coordinates when catype = "CA", or catype = "NSCA".
Row standard coordinates	The row standard coordinates when catype = "CA", or catype = "NSCA".
Column standard coordinates	The column standard coordinates when catype = "CA", or catype = "NSCA".
Row principal polynomial coordinates	The row principal polynomial coordinates when catype = "DOCA", catype = "DONSCA", catype = "SOCA", or catype = "SONSCA".
Column principal polynomial coordinates	The column principal coordinates when catype = "DOCA", or catype = "DONSCA".

`Row standard polynomial coordinates`
: The row standard polynomial coordinates when `catype` is `"DOCA"` or `"DONSCA"`.

`Column standard polynomial coordinates`
: The column standard polynomial coordinates when `catype = "DOCA"`, `catype = "DONSCA"`, `catype = "SOCA"`, or `catype = "SONSCA"`.

`Total inertia`
: The total inertia. For example, for non symmetrical correspondence analysis the numerator of the Goodman-Kruskal tau index, its C-statistic and p-value are returned.

`Polynomial components`
: The polynomial components of the total inertia and their p-values. The total inertia of the column space is partitioned to identify polynomial components. when `catype = "SOCA"` or `catype = "SONSCA"`. When `catype = "DOCA"` or `catype = "DONSCA"`, the total inertia of both the row and column space is partitioned to give the polynomial components.

`Inner product`
: The inner product of the biplot coordinates for the two-dimensional plot.

Examples

```
asbestos <- matrix(c(310, 36, 0, 0, 212, 158, 9, 0, 21, 35, 17, 4, 25, 102,
49, 18, 7, 35, 51, 28), 4, 5, dimnames = list(c("none","grade1", "grade2", "grade3"),
c("0-9", "10-19", "20-29", "30-39", "40")))
risasbestos <- CAvariants(asbestos, catype = "DOCA", firstaxis = 1, lastaxis = 2)
summary(risasbestos)
```

---

trendplot *Plot of reconstructed centred row and column profiles*

Description

This function portrays the trend of the centred row and column of the column profile matrix that are reconstructed using othogonal polynomials and/or principal axes.

Usage

```
trendplot(mf, mg, cex = 1, cex.lab = 0.8, prop = 0.5, posleg = "topleft",
xlab = "First Principal Axis", ylab = "Second Principal Axis")
```

Arguments

mf	The number of row or column categories. By defaults, natural numbers.
mg	The inner product matrix.
cex	The parameter for setting the size of the character labels for the points in a graphical display. By default, `cex = 0.8`.
cex.lab	The parameter for setting the size of character labels of axes in graphical displays. By default, `cex.lab = 0.8`.
prop	The scaling parameter for specifying the limits of the plotting area. By default, `prop = 0.5`.
posleg	The position of the legend when portraying trends of the categories for ordered variants of correspondence analysis. By default, `posleg = "topleft"`.
xlab	The parameter for setting the character label along the horizontal axis of the graphical display.
ylab	The parameter for setting the character label along the vertical axis of the graphical display.

Note

This function is called from the main plot function `plot.CAvariants`.
