Package ‘DescTools’

March 12, 2020

Type Package

Title Tools for Descriptive Statistics

Version 0.99.34

Date 2020-03-12

Description A collection of miscellaneous basic statistic functions and convenience wrappers for efficiently describing data. The author’s intention was to create a toolbox, which facilitates the (notoriously time consuming) first descriptive tasks in data analysis, consisting of calculating descriptive statistics, drawing graphical summaries and reporting the results. The package contains furthermore functions to produce documents using MS Word (or PowerPoint) and functions to import data from Excel. Many of the included functions can be found scattered in other packages and other sources written partly by Titans of R. The reason for collecting them here, was primarily to have them consolidated in ONE instead of dozens of packages (which themselves might depend on other packages which are not needed at all), and to provide a common and consistent interface as far as function and arguments naming, NA handling, recycling rules etc. are concerned. Google style guides were used as naming rules (in absence of convincing alternatives). The ‘camel style’ was consequently applied to functions borrowed from contributed R packages as well.

Suggests RDCOMClient, tcltk, VGAM

Depends base, stats, R (>= 3.6.0)

Imports graphics, grDevices, methods, MASS, utils, boot, mvtnorm, expm, Rcpp (>= 0.12.10)

LinkingTo Rcpp, BH

License GPL (>= 2)

LazyLoad yes

LazyData yes

DescTools-package

Tools for Descriptive Statistics and Exploratory Data Analysis

Description

DescTools is an extensive collection of miscellaneous basic statistics functions and comfort wrappers not available in the R basic system for efficient description of data. The author’s intention was to create a toolbox, which facilitates the (notoriously time consuming) first descriptive tasks in data analysis, consisting of calculating descriptive statistics, drawing graphical summaries and reporting the results. The package contains furthermore functions to produce documents using MS Word (or PowerPoint) and functions to import data from Excel.

A considerable part of the included functions can be found scattered in other packages and other sources written partly by Titans of R. The reason for collecting them here, was primarily to have them consolidated in ONE instead of dozens of packages (which themselves might depend on other packages which are not needed at all), and to provide a common and consistent interface as far as function and arguments naming, NA handling, recycling rules etc. are concerned. Google style guides were used as naming rules (in absence of convincing alternatives). The ‘CamelStyle’ was consequently applied to functions borrowed from contributed R packages as well.
Feedback, feature requests, bugreports and other suggestions are welcome! Please report problems to Stack Overflow using tag [descTools] or directly to the maintainer.

Details

A grouped list of the functions:

**Operators, calculus, transformations:**

- `%(%)`: Between operators determine if a value lies within a range \([a,b]\)
- `%(%)`: Outside operators: `%)(%`, `%%(%, %)(%`, `%]/%`
- `%nin%`: "not in" operator
- `%overlaps%`: Do two collections have common elements?
- `%like%, %like any%`: Simple operator to search for a specified pattern
- `%%^%`: Powers of matrices
- `Interval`: The number of days of the overlapping part of two date periods
- `AUC`: Area under the curve
- `Primes`: Find all primes less than `n`
- `Factorize`: Prime factorization of integers
- `Divisors`: All divisors of an integer
- `GCD`: Greatest common divisor
- `LCM`: Least common multiple
- `Permn`: Determine all possible permutations of a set
- `Fibonacci`: Generates single Fibonacci numbers or a Fibonacci sequence
- `DigitSum`: Digit sum of a number
- `Frac`: Return the fractional part of a numeric value
- `Ndec`: Count decimal places of a number
- `MaxDigits`: Maximum used digits for a vector of numbers
- `Prec`: Precision of a number
- `BoxCox, BoxCoxInv`: Box Cox transformation and its inverse transformation
- `BoxCoxLambda`: Return the optimal lambda for a BoxCox transformation
- `LogSt, LogStInv`: Calculate started logarithmic transformation and it’s inverse
- `Logit, LogitInv`: Generalized logit and inverse logit function
- `LinScale`: Simple linear scaling of a vector `x`
- `Winsorize`: Data cleaning by winsorization
- `Trim`: Trim data by omitting outlying observations
- `CutQ`: Cut a numeric variable into quartiles or other quantiles
- `Recode`: Recode a factor with altered levels
- `Rename`: Change name(s) of a named object
- `Sort`: Sort extension for matrices and data.frames
- `SortMixed, OrderMixed`: Mixed sort order
- `DenseRank`: Calculate ranks in consecutive order (no ties)
- `PercentRank`: Calculate the percent rank
- `RoundTo`: Round to a multiple
- `Large, Small`: Returns the kth largest, resp. smallest values
- `HighLow`: Combines `Large` and `Small`
- `Rev`: Reverses the order of rows and/or columns of a matrix or a data.frame
DescTools-package

- **Untable**: Recreates original list based on a n-dimensional frequency table
- **CollapseTable**: Collapse some rows/columns in a table.
- **Dummy**: Generate dummy codes for a factor
- **FisherZ, FisherZInv**: Fisher’s z-transformation and its inverse
- **Midx**: Calculate sequentially the midpoints of the elements of a vector
- **Unwhich**: Inverse function to which, create a logical vector/matrix from indices
- **Vigenere**: Implements a Vigenere cypher, both encryption and decryption
- **BinTree, PlotBinTree**: Create and plot a binary tree structure with a given length

### Information and manipulation functions:

- **AllDuplicated**: Find all values involved in ties
- **Closest**: Return the value in a vector being closest to a given one
- **Coalesce**: Return the first value in a vector not being NA
- **ZeroIfNA, NAIfZero**: Replace NAs by 0, resp. vice versa
- **Impute**: Replace NAs by the median or another value
- **LOCF**: Imputation of datapoints following the "last observation carried forward" rule
- **CombN**: Returns the number of subsets out of a list of elements
- **CombSet**: Generates all possible subsets out of a list of elements
- **CombPairs**: Generates all pairs out of one or two sets of elements
- **Sample Twins**: Create sample using stratifying groups
- **RndPairs**: Create pairs of correlated random numbers
- **RndWord**: Produce random combinations of characters
- **IsNumeric**: Check a vector for being numeric, zero Or a whole number
- **IsWhole**: Is x a whole number?
- **IsDichotomous**: Check if x contains exactly 2 values
- **IsOdd**: Is x even or odd?
- **IsPrime**: Is x a prime number?
- **IsZero**: Is numeric(x) == 0, say x < machine.eps?
- **IsEuclid**: Check if a distance matrix is euclidean
- **Label, Unit**: Get or set the label, resp. unit, attribute of an object
- **Abind**: Bind matrices to n-dimensional arrays
- **Append**: Append elements to several classes of objects
- **VecRot, VecShift**: Shift the elements of a vector in a circular mode to the right or to the left by n characters.
- **Clockwise**: Transform angles from counter clock into clockwise mode
- **split.formula**: A formula interface for the base function split
- **reorder.factor**: Reorder the levels of a factor
- **ToLong, ToWide**: Simple reshaping of a vector
- **SetNames**: Set the names, rownames or columnnames in an object and return it
- **Some**: Return some randomly chosen elements of an object
- **SplitAt**: Split a vector into several pieces at given positions
- **SplitPath**: Split a path string in drive, path, filename
- **Str**: Compactly display the structure of any R object
- **TextToTable**: Converts a string to a table
String functions:

- **StrCountW**: Count the words in a string
- **StrTrim**: Delete white spaces from a string
- **StrTrunc**: Truncate string on a given length and add ellipses if it really was truncated
- **StrLeft, StrRight**: Returns the left/right part or the a string.
- **StrAlign**: Align strings to the left/right/center or to a given character
- **StrAbbr**: Abbreviates a string
- **StrCap**: Capitalize the first letter of a string
- **StrPad**: Fill a string with defined characters to fit a given length
- **StrRev**: Reverse a string
- **StrChop**: Split a string by a fixed number of characters.
- **StrExtract**: Extract a part of a string, defined as regular expression.
- **StrVal**: Extract numeric values from a string
- **StrIsNumeric**: Check whether a string does only contain numeric data
- **StrPos**: Find position of first occurrence of a string in another one
- **StrDist**: Compute Levenshtein or Hamming distance between strings
- **FixToTable**: Create table out of a running text, by using columns of spaces as delimiter

Conversion functions:

- **AscToChar, CharToAsc**: Converts ASCII codes to characters and vice versa
- **DecToBin, BinToDec**: Converts numbers from binmode to decimal and vice versa
- **DecToHex, HexToDec**: Converts numbers from hexmode to decimal and vice versa
- **DecToOct, OctToDec**: Converts numbers from octmode to decimal and vice versa
- **DegToRad, RadToDeg**: Convert degrees to radians and vice versa
- **CartToPol, PolToCart**: Transform cartesian to polar coordinates and vice versa
- **CartToSph, SphToCart**: Transform cartesian to spherical coordinates and vice versa
- **RomanToInt**: Convert roman numerals to integers
- **RgbToLong, LongToRgb**: Convert a rgb color to a long number and vice versa
- **ColToGray, ColToGrey**: Convert colors to gcrey/grayscale
- **ColToHex, HexToCol**: Convert a color into hex string
- **HexToRgb**: Convert a hexnumber to an RGB-color
- **ColToHsv**: R color to HSV conversion
- **ColToRgb, RgbToCol**: Color to RGB conversion and back
- **ConvUnit**: Return the most common unit conversions

Colors:

- **SetAlpha**: Add transperancy (alpha channel) to a color.
- **ColorLegend**: Add a color legend to a plot
- **FindColor**: Get color on a defined color range
- **MixColor**: Get the mix of two colors
- **TextContrastColor**: Choose textcolor depending on background color
- **Pal**: Some custom color palettes

Plots (low level):
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>Canvas</td>
<td>Canvas for geometric plotting</td>
</tr>
<tr>
<td>Mar</td>
<td>Set margins more comfortably.</td>
</tr>
<tr>
<td>Asp</td>
<td>Return aspect ratio of the current plot</td>
</tr>
<tr>
<td>LineToUser</td>
<td>Convert line coordinates to user coordinates</td>
</tr>
<tr>
<td>lines.loess</td>
<td>Add a loess smoother and its CIs to an existing plot</td>
</tr>
<tr>
<td>lines.lm</td>
<td>Add the prediction of linear model and its CIs to a plot</td>
</tr>
<tr>
<td>lines.smooth.spline</td>
<td>Add the prediction of a smooth.spline and its CIs to a plot</td>
</tr>
<tr>
<td>BubbleLegend</td>
<td>Add a legend for bubbles to a bubble plot</td>
</tr>
<tr>
<td>TitleRect</td>
<td>Add a main title to a plot surrounded by a rectangular box</td>
</tr>
<tr>
<td>BarText</td>
<td>Add the value labels to a barplot</td>
</tr>
<tr>
<td>ErrBars</td>
<td>Add horizontal or vertical error bars to an existing plot</td>
</tr>
<tr>
<td>DrawArc, DrawRegPolygon</td>
<td>Draw elliptic, circular arc(s) or regular polygon(s)</td>
</tr>
<tr>
<td>DrawCircle, DrawEllipse</td>
<td>Draw a circle, a circle annulus or a sector or an annulus</td>
</tr>
<tr>
<td>DrawBezier</td>
<td>Draw a Bezier curve</td>
</tr>
<tr>
<td>DrawBand</td>
<td>Draw confidence band</td>
</tr>
<tr>
<td>BoxedText</td>
<td>Add text surrounded by a box to a plot</td>
</tr>
<tr>
<td>Rotate</td>
<td>Rotate a geometric structure</td>
</tr>
<tr>
<td>SpreadOut</td>
<td>Spread out a vector of numbers so that there is a minimum interval between any two elements. This can be used to place text labels in a plot so that they do not overlap.</td>
</tr>
<tr>
<td>IdentifyA</td>
<td>Helps identifying all the points in a specific area.</td>
</tr>
<tr>
<td>identify.formula</td>
<td>Formula interface for identify.</td>
</tr>
<tr>
<td>PtnPoly</td>
<td>Identify all the points within a polygon.</td>
</tr>
<tr>
<td>ConnLines</td>
<td>Calculate and insert connecting lines in a barplot</td>
</tr>
<tr>
<td>AxisBreak</td>
<td>Place a break mark on an axis</td>
</tr>
<tr>
<td>Shade</td>
<td>Produce a shaded curve</td>

<tr>
<td>PlotPolar</td>
<td>Plot values on a circular grid</td>
</tr>
<tr>
<td>PlotFun</td>
<td>Plot mathematical expression or a function</td>
</tr>
</tbody>
</table>
PolarGrid: Plot a grid in polar coordinates
PlotPyramid: Pyramid plot (back-back histogram)
PlotTreemap: Plot of a treemap.
PlotVenn: Plot a Venn diagram
PlotViolin: Plot violins instead of boxplots
PlotQQ: QQ-plot for an optional distribution
PlotWeb: Create a web plot
PlotTernary: Create a triangle or ternary plot
PlotMiss: Plot missing values
PlotECDF: Plot empirical cumulative distribution function
PlotLinesA: Plot the columns of one matrix against the columns of another
PlotLog: Create a plot with logarithmic axis and log grid
PlotMosaic: Plots a mosaic describing a contingency table in array form

Distributions:
_Benf: Benford distribution, including qBenf, dBenf, rBenf
_ExtrVal: Extreme value distribution (dExtrVal)
_Frechet: Frechet distribution (dFrechet)
_GenExtrVal: Generalized Extreme Value Distribution (dGenExtrVal)
_GenPareto: Generalized Pareto Distribution (dGenPareto)
_Gompertz: Gompertz distribution (dGompertz)
_Gumbel: Gumbel distribution (dGumbel)
_NegWeibull: Negative Weibull distribution (dNegWeibull)
_Order: Distributions of Order Statistics (dOrder)
_RevGumbel: Reverse Gumbel distribution (dRevGumbel)
_RevGumbelExp: Exponential reverse Gumbel distribution (quantile only)
_RevWeibull: Reverse Weibull distribution (dRevWeibull)

Statistics:
Freq: Univariate frequency table
PercTable: Bivariate percentage table
Margins: (Extended) margin tables of a table
ExpFreq: Expected frequencies of an n-dimensional table
Mode: Mode, the most frequent value (including frequency)
Gmean, Gsd: Geometric mean and geometric standard deviation
Hmean: Harmonic Mean
Median: Extended median function supporting weights and ordered factors
HuberM, TukeyBiweight: Huber M-estimator of location and Tukey’s biweight robust mean
HodgesLehmann: the Hodges-Lehmann estimator
HoeffD: Hoeffding’s D statistic
MeanSE: Standard error of mean
MeanCI, MedianCI: Confidence interval for the mean and median
MeanDiffCI: Confidence interval for the difference of two means
MoveAvg: Moving average
MeanAD: Mean absolute deviation
VarCI: Confidence interval for the variance

Coefficient of variation and its confidence interval
Robust data standardization
(Robust) range
Confidence intervals for binomial and multinomial proportions
Calculate confidence interval for a risk difference
Calculate confidence interval for the ratio of binomial proportions.
Confidence interval for a Poisson lambda
Skewness and kurtosis
Yule’s Q and Yule’s Y
Tschuprow’s T
Phi, Pearson’s Contingency Coefficient and Cramer’s V
Goodman Kruskal’s gamma
Kendall’s tau-a
Kendall’s tau-b
Stuart’s tau-c
Somers’ delta
Goodman Kruskal’s lambda
Goodman Kruskal’s tau
Uncertainty coefficient
Shannon’s entropy, mutual information
Rao’s diversity coefficient (“quadratic entropy”)
Theil’s U1 and U2 coefficient
Combines the association measures above.
Odds ratio and relative risk
Transform odds ratio to relative risk
Cohen’s Kappa, weighted Kappa and Kappa for more than 2 raters
Cronbach’s alpha
Intraclass correlations
Return Kripp’s alpha coefficient
Compute the Kendall coefficient of concordance
Calculate and plot Lorenz curve
Gini- and Atkinson coefficient
Herfindahl- and Rosenbluth coefficient
Compute Gini-Simpson Coefficient
Confidence interval for Pearson’s correlation coefficient
Find the correlations for a set x of variables with set y removed
Polychoric correlation coefficient
Spearman rank correlation and its confidence intervals
Return concordant and discordant pairs of two vectors
Determine highly correlated variables
Cohen’s Effect Size
Effect size calculations for ANOVAs
Generate pairwise contrasts for using in a post-hoc test
Stratified sampling with equal/unequal probabilities
Outliers following Tukey’s boxplot definition
Local outlier factor
Brier score, assessing the quality of predictions of binary events

| Date functions:                  |                                                                             |
| day.name, day.abb                | Defined names of the days                                                   |
| AddMonths, AddMonthsYM           | Add a number of months to a given date                                      |
| IsDate                           | Check whether x is a date object                                            |
| IsWeekend                        | Check whether x falls on a weekend                                          |
| IsLeapYear                       | Check whether x is a leap year                                              |
| LastDayOfMonth                   | Return the last day of the month of the date x                             |
| DiffDays360                      | Calculate the difference of two dates using the 360-days system             |
| Date, Month, Year, Year          | Create a date from numeric representation of year, month, day               |
| Hour, Minute, Second             | Extract part of a date                                                      |
| Week, Weekday                    | Extract part of time                                                        |
| Quarter                          | Quarter of a date                                                           |
| Timezone                         | Timezone of a POSIXct/POSIXlt date                                          |
| YearDay, YearMonth               | The day in the year of a date                                               |
| Now, Today                       | Get current date or date-time                                               |
| HmsToSec, SecToHms               | Convert h:m:s times to seconds and vice versa                               |
| Overlap                          | Determine if and how extensively two date ranges overlap                    |
| Zodiac                           | The zodiac sign of a date :-)                                               |

| Finance functions:               |                                                                             |
| OPR                              | One period returns (simple and log returns)                                 |
| NPV                              | Net present value                                                          |
| NPVFixBond                       | Net present value for fix bonds                                             |
| IRR                              | Internal rate of return                                                    |
| YTM                              | Return yield to maturity for a bond                                        |
| SLN, DB, SYD                     | Several methods of depreciation of an asset                                 |

| GUI-Helpers:                     |                                                                             |
| PasswordDlg                      | Display a dialog containing an edit field, showing only ***.               |

| Reporting, InOut:               |                                                                             |
| CatTable                        | Print a table with the option to have controlled linebreaks                 |
| Format, Fmt                     | Easy format for numbers and dates                                          |
| Desc                             | Produce a rich description of an object                                     |

Warning

This package is still under development. Although the code seems meanwhile quite stable, until release of version 1.0 (which is expected in hmmm: new future?) you should be aware that everything in the package might be subject to change. Backward compatibility is not yet guaranteed. Functions may be deleted or renamed and new syntax may be inconsistent with earlier versions. By release of version 1.0 the "deprecated-defunct process" will be installed.

MS-Office

To make use of MS-Office features you must have Office in one of its variants installed. All Wrd*, XL* and Pp* functions require as well the package RDCOMClient to be installed. Hence the use of these functions is restricted to Windows systems. RDCOMClient can be installed with:

install.packages("RDCOMClient", repos="http://www.omegahat.net/R")

The omegahat repository does not benefit from the same update service as CRAN. So you may be forced to install a package compiled with an earlier version, which usually is not a problem. Use e.g. for R 3.6x

url <- "http://www.omegahat.net/R/bin/windows/contrib/3.5.1/RDCOMClient_0.93-0.zip"
install.packages(url, repos=NULL, type="binary")

RDCOMClient does not exist for Mac or Linux, sorry.

Abind

Combine Multidimensional Arrays

Description

Base R functions `cbind` and `rbind` bind columns and rows, but there’s no built-in function for binding higher dimensional datastructures like matrices. `Abind` takes a sequence of vectors, matrices, or arrays and produces a single array of the same or higher dimension.

Usage

```r
Abind(..., along = N, rev.along = NULL, new.names = NULL, force.array = TRUE,
    make.names = FALSE, use.first.dimnames = FALSE, hier.names = FALSE,
    use.dnns = FALSE)
```
Arguments

Any number of vectors, matrices, arrays, or data frames. The dimensions of all the arrays must match, except on one dimension (specified by `along`). If these arguments are named, the name will be used for the name of the dimension along which the arrays are joined. Vectors are treated as having a dim attribute of length one.

Alternatively, there can be one (and only one) list argument supplied, whose components are the objects to be bound together. Names of the list components are treated in the same way as argument names.

**along**

The dimension along which to bind the arrays. The default is the last dimension, i.e., the maximum length of the dim attribute of the supplied arrays. `along` can take any non-negative value up to the minimum length of the dim attribute of supplied arrays plus one. When `along` has a fractional value, a value less than 1, or a value greater than N (N is the maximum of the lengths of the dim attribute of the objects to be bound together), a new dimension is created in the result. In these cases, the dimensions of all arguments must be identical.

**rev.along**

Alternate way to specify the dimension along which to bind the arrays: `along = N + 1 - rev.along`. This is provided mainly to allow easy specification of `along = N + 1` (by supplying `rev.along=0`). If both `along` and `rev.along` are supplied, the supplied value of `along` is ignored.

**new.names**

If `new.names` is a list, it is the first choice for the dimnames attribute of the result. It should have the same structure as a dimnames attribute. If the names for a particular dimension are `NULL`, names for this dimension are constructed in other ways.

If `new.names` is a character vector, it is used for dimension names in the same way as argument names are used. Zero length ("") names are ignored.

**force.array**

If `FALSE`, `rbind` or `cbind` are called when possible, i.e., when the arguments are all vectors, and `along` is not 1, or when the arguments are vectors or matrices or data frames and `along` is 1 or 2. If `rbind` or `cbind` are used, they will preserve the data.frame classes (or any other class that `r/cbind` preserve). Otherwise, `Abind` will convert objects to class array. Thus, to guarantee that an array object is returned, supply the argument `force.array=TRUE`. Note that the use of `rbind` or `cbind` introduces some subtle changes in the way default dimension names are constructed: see the examples below.

**make.names**

If `TRUE`, the last resort for dimnames for the along dimension will be the deparsed versions of anonymous arguments. This can result in cumbersome names when arguments are expressions.

The default is `FALSE`.

**use.first.dimnames**

When dimension names are present on more than one argument, should dimension names for the result be take from the first available (the default is to take them from the last available, which is the same behavior as `rbind` and `cbind`.)

**hier.names**

If `TRUE`, dimension names on the concatenated dimension will be composed of the argument name and the dimension names of the objects being bound. If a single list argument is supplied, then the names of the components serve as the argument names. `hier.names` can also have values "before" or "after"; these
determine the order in which the argument name and the dimension name are put together (TRUE has the same effect as "before").

use.dnns (default FALSE) Use names on dimensions, e.g., so that names(dimnames(x)) is non-empty. When there are multiple possible sources for names of dimnames, the value of use.first.dimnames determines the result.

Details
The dimensions of the supplied vectors or arrays do not need to be identical, e.g., arguments can be a mixture of vectors and matrices. Abind coerces arguments by the addition of one dimension in order to make them consistent with other arguments and along=. The extra dimension is added in the place specified by along=.

The default action of Abind is to concatenate on the last dimension, rather than increase the number of dimensions. For example, the result of calling Abind with vectors is a longer vector (see first example below). This differs from the action of rbind and cbind which is to return a matrix when called with vectors. Abind can be made to behave like cbind on vectors by specifying along=2, and like rbind by specifying along=0.

The dimnames of the returned object are pieced together from the dimnames of the arguments, and the names of the arguments. Names for each dimension are searched for in the following order: new.names, argument name, dimnames (or names) attribute of last argument, dimnames (or names) attribute of second last argument, etc. (Supplying the argument use.first.dimnames=TRUE changes this to cause Abind to use dimnames or names from the first argument first. The default behavior is the same as for rbind and cbind: use dimnames from later arguments.) If some names are supplied for the along dimension (either as argument names or dimnames in arguments), names are constructed for anonymous arguments unless maken.ames=FALSE.

Value
An array with a dim attribute calculated as follows.

Let rMin=min(sapply(list(...),function(x) length(dim(x)))) and rMax=max(sapply(list(...),function(x) length(dim(x)))) (where the length of the dimensions of a vector are taken to be 1). Then rMax should be equal to or one greater than rMin.

If along refers to an existing dimension, then the length of the dim attribute of the result is rMax. If along does not refer to an existing dimension, then rMax should equal rMin and the length of the dim attribute of the result will be rMax+1.

rbind or cbind are called to compute the result if (a) force.array=FALSE; and (b) the result will be a two-dimensional object.

Note
It would be nice to make Abind() an S3 generic, but S3 generics cannot dispatch off anonymous arguments.

The ability of Abind() to accept a single list argument removes much of the need for constructs like do.call("Abind",list.of.arrays). Instead, just do Abind(list.of.arrays). The direct construct is preferred because do.call() construct can sometimes consume more memory during evaluation.

rbind, cbind, array

Examples

# Five different ways of binding together two matrices
x <- matrix(1:12, 3, 4)
y <- x + 100
dim(Abind(x, y, along=0))  # binds on new dimension before first
dim(Abind(x, y, along=1))  # binds on first dimension
dim(Abind(x, y, along=1.5))
dim(Abind(x, y, along=2))
dim(Abind(x, y, along=3))
dim(Abind(x, y, rev.along=1))  # binds on last dimension
dim(Abind(x, y, rev.along=0))  # binds on new dimension after last

# Unlike cbind or rbind in that the default is to bind
# along the last dimension of the inputs, which for vectors
# means the result is a vector (because a vector is
# treated as an array with length(dim(x))==1).
Abind(x=1:4, y=5:8)

# Like cbind
Abind(x=1:4, y=5:8, along=2)
Abind(x=1:4, matrix(5:20, nrow=4), along=2)
Abind(1:4, matrix(5:20, nrow=4), along=2)

# Like rbind
Abind(x=1:4, matrix(5:20, nrow=4), along=1)
Abind(1:4, matrix(5:20, nrow=4), along=1)

# Create a 3-d array out of two matrices
Abind(x=matrix(1:16, nrow=4), y=matrix(17:32, nrow=4), along=3)

# Use of hier.names
Abind(x=cbind(a=1:3, b=4:6), y=cbind(a=7:9, b=10:12), hier.names=TRUE)

# Use a list argument
Abind(list(x=x, y=x), along=3)
# Use lapply(..., get) to get the objects
an <- c('x', 'y')
names(an) <- an
Abind(lapply(an, get), along=3)
Abstract

Display Compact Abstract of a Data Frame

Description

Compactly display the content and structure of a data.frame, including variable labels. \texttt{str} is optimised for lists and its output is relatively technical, when it comes to e.g. attributes. \texttt{summary} on the other side already calculates some basic statistics.

Usage

\begin{verbatim}
Abstract(x, sep = ",", zero.form = ".", maxlevels = 5, trunc = TRUE, list.len = 999)
\end{verbatim}

Arguments

- \texttt{x} a \texttt{data.frame} to be described
- \texttt{sep} the separator for concatenating the levels of a factor
- \texttt{zero.form} a symbol to be used, when a variable has zero NAs.
- \texttt{maxlevels} integer, defining how many factor levels are to be displayed. Default is 12. Set this to Inf, if all levels are needed.
- \texttt{trunc} logical, defining if level names exceeding the column with should be truncated. Default ist TRUE.
- \texttt{list.len} numeric; maximum number of list elements to display.

Details

The levels of a factor and describing variable labels (as created by \texttt{Label}) will be wrapped within the columns.

The first 4 columns are printed with the needed fix width, the last 2 (Levels and Labels) are wrapped within the column. The width is calculated depending on the width of the screen as given by \texttt{getOption("width")}.

\texttt{ToWord} has an interface for the class \texttt{abstract}.

Value

an object of class \texttt{abstract}, essentially a character matrix with 5 or 6 columns containing a sequential \texttt{nr} (Nr), the name of the column (ColName), the class (Class), the number of NAs (NAs), the levels if the variable is a factor (Levels) and - if there are any - descriptive labels for the column (Labels).

str, summary, ColumnWrap

Examples

d.mydata <- d.pizza
# let's use some labels
Label(d.mydata) <- "Lorem ipsum dolor sit amet, consetetur sadipscing elitr, sed diam nonumy eirmod tempor invidunt ut labore et dolore magna aliquyam erat, sed diam voluptua. At vero eos et accusam."

Label(d.mydata$temperature) <- "Amet, consetetur sadipscing elitr, sed diam nonumy "

Abstract(d.mydata)

AddMonths(x, n, ...)

Arguments

x a Date object (or something which can be coerced by as.Date(x, ...) to such an object) to which a number of months has to be added.
n the number of months to be added. If n is negative the months will be subtracted.
... the dots are passed to as.Date, e.g. for supplying origin.

Details

All parameters will be recycled if necessary.

Value

a vector of class Date with the same dimension as x, containing the transformed dates.

Author(s)

Andri Signorell <andri@signorell.net>, based on code by Roland Rapold and Antonio
AddMonthsYM

Add a Month to a Date in YearMonth Format

Description

The representation of year and month information in YYYYMM format as an integer is sometimes a useful and efficient data structure. Adding a number of months to such a date is not quite catchy, however, since the date structure is to be retained. For example, 201201 - 2 [months] is expected to result in 201111 instead of 201199. AddMonthsYM does this job.

Usage

AddMonthsYM(x, n)

Arguments

x a vector of integers, representing the dates in the format YYYYMM, to which a number of months has to be added.

n the number of months to be added. If n is negative the months will be subtracted.
Details

All parameters will be recycled if necessary. The therefore used function `mapply` will display a warning, if the longer argument is not a multiple of the length of the shorter one.

Value

A vector of class integer with the same dimension as x, containing the transformed dates.

Author(s)

Andri Signorell <andri@signorell.net>, based on code by Roland Rapold

See Also

`AddMonths`; Date functions, like `Year`, `Month`, etc.

Examples

```r
AddMonthsYM(201511, 5)
AddMonthsYM(c(201511, 201302), c(5, 15))
AddMonthsYM(c(201511, 201302), c(5, -4))
```

Description

Computes raw simple and extended percentage agreement among raters.

Usage

```r
Agree(x, tolerance = 0, na.rm = FALSE)
```

Arguments

- `x`: a data.frame or a \( k \times m \) matrix, \( k \) subjects (in rows) \( m \) raters (in columns).
- `tolerance`: number of successive rating categories that should be regarded as rater agreement (see details).
- `na.rm`: logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.

Details

Using extended percentage agreement (tolerance \(!= 0\)) is only possible for numerical values. If tolerance equals 1, for example, raters differing by one scale degree are interpreted as agreeing.
Value

numeric value of coefficient of interrater reliability

The number of finally (potentially after omitting missing values) used subjects and raters are returned as attributes:

subjects the number of subjects examined.
raters the number of raters.

AllDuplicated Index Vector of All Values Involved in Ties

Description

The function duplicated returns a logical vector indicating which elements x are duplicates, but will not include the very first appearance of subsequently duplicated elements. AllDuplicated returns an index vector of ALL the values in x which are involved in ties. So !AllDuplicated can be used to determine all elements of x, which appear exactly once (thus with frequency 1).

Usage

AllDuplicated(x)

Arguments

x vector of any type.
Value

logical vector of the same dimension as x.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

unique returns a unique list of all values in x
duplicated returns an index vector flagging all elements, which appeared more than once (leaving out the first appearance!)
union(A, B) returns a list with the unique values from A and B intersect returns all elements which appear in A and in B setdiff(A, B) returns all elements appearing in A but not in B setequal(A, B) returns TRUE if A contains exactly the same elements as B split(A, A) returns a list with all the tied values in A (see examples)

Examples

x <- c(1:10, 4:6)
AllDuplicated(x)

# compare to:
duplicated(x)

x[!AllDuplicated(x)]

# union, intersect and friends...
A <- c(sort(sample(1:20, 9)),NA)
B <- c(sort(sample(3:23, 7)),NA)

# all elements from A and B (no duplicates)
union(A, B)
# all elements appearing in A and in B
intersect(A, B)
# elements in A, but not in B
setdiff(A, B)
# elements in B, but not in A
setdiff(B, A)
# Does A contain the same elements as B?
setequal(A, B)

# Find ties in a vector x
x <- sample(letters[1:10], 20, replace=TRUE)
ties <- split(x, x)

# count tied groups
AllIdentical

Description

The function `identical()` is the safe and reliable way to test two objects for being exactly equal. But it is restricted to the comparison of two objects. `AllIdentical()` allows the input of multiple objects and returns TRUE in the case that all of them are exactly equal, FALSE in every other case.

Usage

`AllIdentical(...)`

Arguments

`...` any R objects

Details

The function checks the first object against all others, so if the first object is identical to the second and to the third, then also the second and the third are identical. (If A=B and A=C then is B=C)

Author(s)

Andri Signorell <andri@signorell.net>

See Also

`identical()`
Examples

```r
A <- LETTERS[1:5]
B <- LETTERS[1:5]
C <- LETTERS[1:5]
D <- LETTERS[1:5]
E <- factor(LETTERS[1:5])

# all ok
AllIdentical(A, B, C, D)

# at least one odd man
AllIdentical(A, B, C, D, E)
```

AndersonDarlingTest

Anderson-Darling Test of Goodness-of-Fit

Description

Performs the Anderson-Darling test of goodness-of-fit to a specified continuous univariate probability distribution.

Usage

```r
AndersonDarlingTest(x, null = "punif", ..., nullname)
```

Arguments

- `x`: numeric vector of data values.
- `null`: a function, or a character string giving the name of a function, to compute the cumulative distribution function for the null distribution.
- `...`: additional arguments for the cumulative distribution function.
- `nullname`: optional character string describing the null distribution. The default is "uniform distribution".

Details

This command performs the Anderson-Darling test of goodness-of-fit to the distribution specified by the argument null. It is assumed that the values in x are independent and identically distributed random values, with some cumulative distribution function \( F \). The null hypothesis is that \( F \) is the function specified by the argument null, while the alternative hypothesis is that \( F \) is some other function.

Value

An object of class "htest" representing the result of the hypothesis test.
Append

Author(s)

Original C code by George Marsaglia and John Marsaglia. R interface by Adrian Baddeley.

References

See Also

`shapiro.test` and all other tests for normality.

Examples

```r
x <- rnorm(10, mean=2, sd=1)
AndersonDarlingTest(x, "pnorm", mean=2, sd=1)
```

Append Elements to Objects

Description

Append elements to a number of various objects as vectors, matrices, data.frames and lists. In a matrix either rows or columns can be inserted at any position. In data frames any vectors can be inserted. values will be recycled to the necessary length.

Usage

```r
Append(x, values, after = NULL, ...)
```

## S3 method for class 'matrix'

```r
Append(x, values, after = NULL, rows = FALSE, names = NULL, ...)
```

## S3 method for class 'data.frame'

```r
Append(x, values, after = NULL, names = NULL, ...)
```

## Default S3 method:

```r
Append(x, values, after = NULL, ...)
```
Append

Arguments

- **x**: object for the elements to be inserted
- **values**: the elements to be inserted
- **after**: a subscript, after which the values are to be appended. If it’s missing the values will be appended after the last element (or column/row).
- **rows**: logical, defining if vector should be added as row or as column. Default is column (rows=FALSE).
- **names**: the dimension names for the inserted elements(s)
- ... further arguments (not used here)

Details

The vector x will be recycled to a length of the next multiple of the number of rows (or columns) of the matrix m and will be inserted such that the first inserted row (column) has the index i. If the dimnames are given, they will be used no matter if the matrix m has already dimnames defined or not.

Value

An object containing the values in x with the elements of values appended after the specified element of x.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

rbind, cbind, append

Examples

```
Append(1:5, 0:1, after = 3)  # the same as append

# Insert columns and rows
x <- matrix(runif(25), 5)
Append(x, values=1:10, after=2, names = c("X","Y"))
Append(x, values=1:10, after=2)

Append(x, values=1:10, after=2, names = c("X","Y"))
Append(x, values=1:10, after=2)

# append to a data.frame
d.frm <- data.frame(id = c(1,2,3),
                     code = c("AAA", "BBB", "CCC"),
                     val = c(111, 222, 333))
z <- c(10, 20, 30)
Append(d.frm, z, after=2, names="ZZZ")
```
Description

Places an arrow into a plot. Two additional arrow heads are implemented.

Usage

\[ \text{Arrow}(x_0, y_0, x_1, y_1, \text{col} = \text{par("bg")}, \text{border} = \text{par("fg")}, \text{head} = 1, \]
\[ \text{cex} = 1, \text{lwd} = 1, \text{lty} = 1) \]

Arguments

- \(x_0, y_0\): coordinates of points from which to draw.
- \(x_1, y_1\): coordinates of points to which to draw. At least one must the supplied.
- \(\text{col}\): the color of the line and background color of the arrow head.
- \(\text{border}\): color of the arrow head.
- \(\text{head}\): type of head, can be one out of 1:3.
- \(\text{cex}\): extension factor for the arrow head.
- \(\text{lwd}\): line width
- \(\text{lty}\): line type

Value

Nothing returned

Examples

\[ \text{Canvas() \ Arrow(1, 1, 0, 0)} \]
Convert xtabs To matrix

Description

This function converts an xtabs object to a matrix.

Usage

## S3 method for class 'xtabs'
as.matrix(x, ...)

Arguments

x an object of class xtabs
...
additional arguments to be passed to or from methods.

Details

An xtabs object is indeed already a matrix, but won’t be converted to a pure matrix by as.matrix.default function, as its class definition will remain unchanged. Some functions expecting a pure matrix may fail, when fed with a xtabs object. as.matrix.xtabs will drop the classes and the call attribute. Note that unclass would as well discard the classes xtabs and table, but retain the “call” attribute.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

as.matrix, xtabs, unclass

Examples

tab <- xtabs(~ driver + operator, data=d.pizza)

class(tab)

str(as.matrix(tab))
class(as.matrix(tab))
AscToChar

Convert ASCII Codes to Characters and Vice Versa

Description

AscToChar returns a character for each ASCII code (integer) supplied.
CharToAsc returns integer codes in 0:255 for each (one byte) character in all strings in x.

Usage

AscToChar(i)
CharToAsc(x)

Arguments

i numeric (integer) vector of values in 1:255.
x vector of strings.

Details

Only codes in 1:127 make up the ASCII encoding which should be identical for all R versions, whereas the ‘upper’ half is often determined from the ISO-8859-1 (aka “ISO-Latin 1”) encoding, but may well differ, depending on the locale setting, see also Sys.setlocale.
Note that 0 is no longer allowed since, R does not allow \0 aka nul characters in a string anymore.

Value

AscToChar returns a vector of the same length as i. CharToAsc returns a list of numeric vectors of character length of each string in x.

Author(s)

unknown guy out there, help text partly taken from M. Maechler’s sfsmisc.

See Also

charToRaw

Examples

(x <- CharToAsc("Silvia"))

# will be pasted together
AscToChar(x)

# use strsplit if the single characters are needed
strsplit(AscToChar(x), split=NULL)
# this would be an alternative, but the latter would be of class raw
DecToHex(CharToAsc("Silvia"))
charToRaw("Silvia")

Asp

Get Aspect Ratio of the Current Plot

Description

Returns the aspect ratio of the current plot in user coordinates.

Usage

Asp()

Details

The aspect ratio of the plot is calculated as

\[
\begin{align*}
    w &= \frac{\text{par("pin")[1]}}{\text{diff(par("usr")[1:2])}} \\
    h &= \frac{\text{par("pin")[2]}}{\text{diff(par("usr")[3:4])}} \\
    \text{asp} &= \frac{w}{h}
\end{align*}
\]

Author(s)

Andri Signorell <andri@signorell.net>

Examples

Asp()

Association measures

Cramer’s V, Pearson’s Contingency Coefficient and Phi Coefficient
Yule’s Q and Y, Tschuprow’s T

Description

Calculate Cramer’s V, Pearson’s contingency coefficient and phi, Yule’s Q and Y and Tschuprow’s T of x, if x is a table. If both, x and y are given, then the according table will be built first.
Association measures

Usage

Phi(x, y = NULL, ...)
ContCoef(x, y = NULL, correct = FALSE, ...)
CramerV(x, y = NULL, conf.level = NA,
method = c("ncchisq", "ncchisqadj", "fisher", "fisheradj"),
correct = FALSE, ...)

YuleQ(x, y = NULL, ...)
YuleY(x, y = NULL, ...)
TschuprowT(x, y = NULL, correct = FALSE, ...)

Arguments

x can be a numeric vector, a matrix or a table.
y NULL (default) or a vector with compatible dimensions to x. If y is provided,
table(x,y,...) is calculated.
conf.level confidence level of the interval. This is only implemented for Cramer's V. If set
to NA (which is the default) no confidence interval will be calculated.
See examples for calculating bootstrap intervals.
method string defining the method to calculate confidence intervals for Cramer's V. One
out of "ncchisq" (using noncentral chisquare), "ncchisqadj", "fisher" (using
fisher z transformation), "fisheradj" (using fisher z transformation and
bias correction). Default is "ncchisq".
correct logical. Applying to ContCoef this indicates, whether the Sakoda's adjusted
Pearson's C should be returned. For CramerV() and TschuprowT() it defines,
whether a bias correction should be applied or not. Default is FALSE.
...

Details

For x either a matrix or two vectors x and y are expected. In latter case table(x,y,...) is cal-
culated. The function handles NAs the same way the table function does, so tables are by default
calculated with NAs omitted.

A provided matrix is interpreted as a contingency table, which seems in the case of frequency
data the natural interpretation (this is e.g. also what chisq.test expects).

Use the function PairApply (pairwise apply) if the measure should be calculated pairwise for all
columns. This allows matrices of association measures to be calculated the same way cor does.
NAs are by default omitted pairwise, which corresponds to the pairwise.complete option of cor.
Use complete.cases, if only the complete cases of a data.frame are to be used. (see examples)

The maximum value for Phi is \(\sqrt{\min(r,c) - 1}\). The contingency coefficient goes from 0 to
\(\sqrt{\frac{\min(r,c) - 1}{\min(r,c)}}\). For the corrected contingency coefficient and for Cramer's V the range is 0 to 1.
A Cramer's V in the range of [0, 0.3] is considered as weak, [0.3,0.7] as medium and > 0.7 as
strong. The minimum value for all is 0 under statistical independence.
Association measures

Value

a single numeric value if no confidence intervals are requested, and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

**Assocs**

**Association Measures**

**Description**
Collects a number of association measures for nominal and ordinal data.

**Usage**

```r
Assocs(x, conf.level = 0.95, verbose = NULL)
```

**Arguments**

- **x** a 2 dimensional contingency table or a matrix.
- **conf.level** confidence level of the interval. If set to `NA` no confidence interval will be calculated. Default is 0.95.
- **verbose** integer out of `c(2,1,3)` defining the verbosity of the reported results. 2 (default) means medium, 1 less and 3 extensive results. Applies only to tables and is ignored else.
- **digits** integer which determines the number of digits used in formatting the measures of association.
- **...** further arguments to be passed to or from methods.
Details
This function wraps the association measures phi, contingency coefficient, Cramer’s V, Goodman
Kruskal’s Gamma, Kendall’s Tau-b, Stuart’s Tau-c, Somers’ Delta, Pearson and Spearman correla-
tion, Guttman’s Lambda, Theil’s Uncertainty Coefficient and the mutual information.

Value
numeric matrix, dimension [1:17, 1:3]
the first column contains the estimate, the second the lower confidence interval, the third the upper
one.

Atkinson Index - A Measure of Inequality.

Description

The Atkinson index is an inequality measure and is useful in determining which end of the distribution contributed most to the observed inequality.

Usage

Atkinson(x, n = rep(1, length(x)), parameter = 0.5, na.rm = FALSE)

Arguments

  x  a vector containing at least non-negative elements.
  n  a vector of frequencies, must be same length as x.
  parameter parameter of the inequality measure (if set to NULL the default parameter of the respective measure is used).
  na.rm  logical. Should missing values be removed? Defaults to FALSE.

Value

the value of the Akinson Index.

Note

This function was previously published as ineq() in the ineq package and has been integrated here without logical changes, but with some extensions for NA-handling and the use of weights.

Author(s)

Achim Zeileis <Achim.Zeileis@R-project.org>

# compute Atkinson coefficient with parameter=0.5
Atkinson(x, parameter=0.5)

---

AUC

Area Under the Curve

Description

Calculate the area under the curve with a naive algorithm and with a more elaborated spline approach. The curve must be given by vectors of xy-coordinates.

Usage

AUC(x, y, from = min(x, na.rm = TRUE), to = max(x, na.rm = TRUE),
  method = c("trapezoid", "step", "spline", "linear"),
  absolutearea = FALSE, subdivisions = 100, na.rm = FALSE, ...)

Arguments

x, y  
the xy-points of the curve

method  
The type of interpolation. Can be "trapezoid" (default), "step", "linear" or "spline". The value "spline" results in the area under the natural cubic spline interpolation.

from  
The value from where to start calculating the area under the curve. Defaults to the smallest x value.

to  
The value from where to end the calculation of the area under the curve. Defaults to the greatest x value.

absolutearea  
A logical value that determines if negative areas should be added to the total area under the curve. By default the auc function subtracts areas that have negative y values. Set absolutearea=TRUE to _add_ the absolute value of the negative areas to the total area. Ignored if method is not spline.

subdivisions  
an integer telling how many subdivisions should be used for integrate (for non-linear approximations). Ignored if method is not spline.

na.rm  
logical, indicating whether NA values should be stripped before the computation proceeds. In this case only the complete cases of x and y will be used. na.rm defaults to FALSE.

...  
additional arguments passed on to approx (for linear approximations). In particular rule can be set to determine how values outside the range of x is handled.
**Details**

If method is set to "trapezoid" then the curve is formed by connecting all points by a direct line (composite trapezoid rule). If "step" is chosen then a stepwise connection of two points is used.

For linear interpolation the AUC() function computes the area under the curve using the composite trapezoid rule. For area under a spline interpolation, AUC() uses the splinefun function in combination with the integrate to calculate a numerical integral.

The AUC() function can handle unsorted time values (by sorting x), missing observations, ties for the x values (by ignoring duplicates), and integrating over part of the area or even outside the area.

**Value**

Numeric value of the area under the curve.

**Author(s)**

Andri Signorell <andri@signorell.net>, spline part by Claus Ekstrom <claus@rprimer.dk>

**See Also**

integrate, splinefun

**Examples**

```r
AUC(x=c(1,3), y=c(1,1))

AUC(x=c(1,2,3), y=c(1,2,4), method="trapezoid")
AUC(x=c(1,2,3), y=c(1,2,4), method="step")

plot(x=c(1,2,2.5), y=c(1,2,4), type="l", col="blue", ylim=c(0,4))
lines(x=c(1,2,2.5), y=c(1,2,4), type="s", col="red")

x <- seq(0, pi, length.out=200)
AUC(x=x, y=sin(x))
AUC(x=x, y=sin(x), method="spline")
```

---

**AxisBreak**

*Place a Break Mark on an Axis*

**Description**

Places a break mark on an axis on an existing plot.

**Usage**

```r
AxisBreak(axis = 1, breakpos = NULL, pos = NA, bgcol = "white",
          breakcol = "black", style = "slash", brw = 0.02)
```
Arguments

- **axis**: which axis to break.
- **breakpos**: where to place the break in user units.
- **pos**: position of the axis (see `axis`).
- **bgcolor**: the color of the plot background.
- **breakcol**: the color of the "break" marker.
- **style**: Either 'gap', 'slash' or 'zigzag'.
- **brw**: break width relative to plot width.

Details

The `pos` argument is not needed unless the user has specified a different position from the default for the axis to be broken.

Note

There is some controversy about the propriety of using discontinuous coordinates for plotting, and thus axis breaks. Discontinuous coordinates allow widely separated groups of values or outliers to appear without devoting too much of the plot to empty space.

The major objection seems to be that the reader will be misled by assuming continuous coordinates.

The ‘gap’ style that clearly separates the two sections of the plot is probably best for avoiding this.

Author(s)

Jim Lemon and Ben Bolker

Examples

```r
plot(3:10, main="Axis break test")

# put a break at the default axis and position
AxisBreak()
AxisBreak(2, 2.9, style="zigzag")
```

---

Compute Axis Tickmark Locations (For POSIXct Axis)

Description

Compute pretty tickmark locations, the same way as R does internally. By default, gives the at values which `axis.POSIXct(side, x)` would use.

Usage

```r
axTicks.POSIXct(side, x, at, format, labels = TRUE, ...)
axTicks.Date(side = 1, x, ...)
```
axTicks.POSIXct

Arguments

side See axis.

x, at A date-time or date object.

format See strftime.

labels Either a logical value specifying whether annotations are to be made at the tickmarks, or a vector of character strings to be placed at the tickpoints.

... Further arguments to be passed from or to other methods.

Details

axTicks has no implementation for POSIXct axis. This function fills the gap.

Value

numeric vector of coordinate values at which axis tickmarks can be drawn.

Author(s)

Andri Signorell <andri@signorell.net> simply copying R-Core code

# now label every hour on the time axis
plot(time, temp, type = "l", xaxt = "n")
r <- as.POSIXct(round(range(time), "hours"))
axis.POSIXct(1, at = seq(r[1], r[2], by = "hour"), format = "%H")
# place the grid
abline(v=axTicks.POSIXct(1, at = seq(r[1], r[2], by = "hour"), format = "%H"),
     col="grey", lty="dotted")
})
BarnardTest

**Description**

Barnard's unconditional test for superiority applied to $2 \times 2$ contingency tables using Score or Wald statistics for the difference between two binomial proportions.

**Usage**

```r
BarnardTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
            dp = 0.001, pooled = TRUE)
```

**Arguments**

- `x`: a numeric vector or a two-dimensional contingency table in matrix form. `x` and `y` can also both be factors.
- `y`: a factor object; ignored if `x` is a matrix.
- `dp`: The resolution of the search space for the nuisance parameter
- `pooled`: Z statistic with pooled (Score) or unpooled (Wald) variance
- `alternative`: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

**Details**

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

For a 2x2 contingency table, such as $X = [n_1, n_2; n_3, n_4]$, the normalized difference in proportions between the two categories, given in each column, can be written with pooled variance (Score statistic) as

$$T(X) = \frac{\hat{p}_2 - \hat{p}_1}{\sqrt{\hat{p}(1 - \hat{p})(\frac{1}{c_1} + \frac{1}{c_2})}},$$

where $\hat{p} = (n_1 + n_3) / (n_1 + n_2 + n_3 + n_4)$, $\hat{p}_2 = n_2 / (n_2 + n_4)$, $\hat{p}_1 = n_1 / (n_1 + n_3)$, $c_1 = n_1 + n_3$ and $c_2 = n_2 + n_4$. Alternatively, with unpooled variance (Wald statistic), the difference in proportions can be written as

$$T(X) = \frac{\hat{p}_2 - \hat{p}_1}{\sqrt{\frac{\hat{p}_1(1 - \hat{p}_1)}{c_1} + \frac{\hat{p}_2(1 - \hat{p}_2)}{c_2}}}.$$

The probability of observing $X$ is

$$P(X) = \frac{c_1!c_2!}{n_1!n_2!n_3!n_4!} p^{n_1 + n_2} (1 - p)^{n_3 + n_4},$$

where $p$ is the unknown nuisance parameter.
Barnard's test considers all tables with category sizes $c_1$ and $c_2$ for a given $p$. The p-value is the sum of probabilities of the tables having a score in the rejection region, e.g. having significantly large difference in proportions for a two-sided test. The p-value of the test is the maximum p-value calculated over all $p$ between 0 and 1.

**Value**

A list with class "htest" containing the following components:

- **p.value**: the p-value of the test.
- **estimate**: an estimate of the nuisance parameter where the p-value is maximized.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: the character string "Barnards Unconditional 2x2-test".
- **data.name**: a character string giving the names of the data.
- **statistic.table**: The contingency tables considered in the analysis represented by 'n1' and 'n2', their scores, and whether they are included in the one-sided (1), two-sided (2) tests, or not included at all (0)
- **nuisance.matrix**: Nuisance parameters, $p$, and the corresponding p-values for both one- and two-sided tests

     t="p", xlab="n1", ylab="n2")
```

BartelsRankTest

Bartels Rank Test of Randomness

Description

Performs the Bartels rank test of randomness, which tests if a sample is sampled randomly from an underlying population. Data must at least be measured on an ordinal scale.

Usage

```r
BartelsRankTest(x, alternative = c("two.sided", "trend", "oscillation"),
                method = c("normal", "beta", "auto"))
```

Arguments

- **x**: a numeric vector containing the observations
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "trend" or "oscillation".
- **method**: a character string specifying the method used to compute the p-value. Must be one of normal (default), beta or auto.
Details
The RVN test statistic is
\[ RVN = \frac{\sum_{i=1}^{n-1} (R_i - R_{i+1})^2}{\sum_{i=1}^{n} (R_i - (n + 1)/2)^2} \]
where \( R_i = \text{rank}(X_i), i = 1, \ldots, n \). It is known that \((RVN - 2)/\sigma\) is asymptotically standard normal, where \( \sigma^2 = \frac{4(n-2)(5n^2-2n-9)}{5n(n+1)(n-1)^2} \).
By using the alternative "trend" the null hypothesis of randomness is tested against a trend. By using the alternative "oscillation" the null hypothesis of randomness is tested against a systematic oscillation.
Missing values are silently removed.
Bartels test is a rank version of von Neumann’s test.

Value
A list with class "htest" containing the components:
- statistic the value of the normalized statistic test.
- parameter, n the size of the data, after the remotion of consecutive duplicate values.
- p.value the p-value of the test.
- alternative a character string describing the alternative hypothesis.
- method a character string indicating the test performed.
- data.name a character string giving the name of the data.
- rvn the value of the RVN statistic (not show on screen).
- nm the value of the NM statistic, the numerator of RVN (not show on screen).
- mu the mean value of the RVN statistic (not show on screen).
- var the variance of the RVN statistic (not show on screen).

BarText

Add the Value Labels to a Barplot

Description

Place text either in the middle of the stacked bars of a barplot or on top of a side by side barplot.

Usage

BarText(height, b, labels = height, beside = FALSE, horiz = FALSE, 
cex = par("cex"), adj = NULL, top = TRUE, ...)

Arguments

- **height**: either a vector or matrix of values describing the bars which make up the plot exactly as used for creating the barplot.
- **b**: the returned mid points as returned by b <- barplot(...).
- **labels**: the labels to be placed on the bars.
- **beside**: a logical value. If FALSE, the columns of height are portrayed as stacked bars, and if TRUE the columns are portrayed as juxtaposed bars.
- **horiz**: a logical value. If FALSE, the bars are drawn vertically with the first bar to the left. If TRUE, the bars are drawn horizontally with the first at the bottom.
**BarText**

- **cex** numeric character expansion factor; multiplied by `par("cex")` yields the final character size. NULL and NA are equivalent to 1.0.
- **adj** one or two values in [0, 1] which specify the x (and optionally y) adjustment of the labels. On most devices values outside that interval will also work.
- **top** logical, defining if the labels should be placed on top of the bars (id beside is set to TRUE). Will be ignored if beside is FALSE.
- ... the dots are passed to the text.

**Details**

It sometimes makes sense to place the data values directly on the bars. The x coordinates of the labels can be found by using `barplot()` result, if they are to be centered at the top of each bar. `BarText()` calculates the rest. Notice that when the labels are placed on top of the bars, they may be clipped. This can be avoided by setting `xpd=TRUE`.

```
Base Conversions

Converts Numbers From Binmode, Octmode or Hexmode to Decimal and Vice Versa

Description

These functions convert numbers from one base to another. There are several solutions for this problem out there, but the naming is quite heterogeneous and so consistent function names might be helpful.

Usage

BinToDec(x)
DecToBin(x)
OctToDec(x)
DecToOct(x)
HexToDec(x)
DecToHex(x)

Arguments

x a vector of numbers, resp. alphanumerical representation of numbers (hex), to be converted.

Details

BinToDec converts numbers from binary mode into decimal values. DecToBin does it the other way round.
Oct means octal system and hex hexadecimal.

Value

A numeric or character vector of the same length as x containing the converted values. Binary, octal and decimal values are numeric, hex-values are returned as class hexmode.

Author(s)

Andri Signorell <andri@signorell.net>

strtoi
Benford's Distribution

Description

Density, distribution function, quantile function, and random generation for Benford's distribution.

Usage

dBenf(x, ndigits = 1, log = FALSE)
pBenf(q, ndigits = 1, log.p = FALSE)
qBenf(p, ndigits = 1)
rBenf(n, ndigits = 1)

Arguments

x, q
Vector of quantiles. See ndigits.
p
vector of probabilities.
n
number of observations. A single positive integer. Else if length(n) > 1 then the length is taken to be the number required.
ndigits
Number of leading digits, either 1 or 2. If 1 then the support of the distribution is \{1, \ldots, 9\}, else \{10, \ldots, 99\}.
log, log.p
Logical. If log.p = TRUE then all probabilities p are given as log(p).

Details

Benford's Law (aka the significant-digit law) is the empirical observation that in many naturally occurring tables of numerical data, the leading significant (nonzero) digit is not uniformly distributed in \{1, 2, \ldots, 9\}. Instead, the leading significant digit (\(= D\), say) obeys the law

\[
P(D = d) = \log_{10} \left(1 + \frac{1}{d}\right)
\]

for \(d = 1, \ldots, 9\). This means the probability the first significant digit is 1 is approximately 0.301, etc.

Benford's Law was apparently first discovered in 1881 by astronomer/mathematician S. Newcomer. It started by the observation that the pages of a book of logarithms were dirtiest at the beginning.
and progressively cleaner throughout. In 1938, a General Electric physicist called F. Benford re-
rediscovered the law on this same observation. Over several years he collected data from different
sources as different as atomic weights, baseball statistics, numerical data from Reader's Digest, and
storage areas of rivers.

Applications of Benford’s Law has been as diverse as to the area of fraud detection in accounting
and the design computers.

Value

dBenf gives the density, pBenf gives the distribution function, and qBenf gives the quantile func-
tion, and rBenf generates random deviates.

Author(s)

T. W. Yee

Source

These functions were previously published as dbenf() etc. in the VGAM package and have been
integrated here without logical changes.

points(xx, dBenf(xx), col = "red")

## End(Not run)
The between and outside operators are used to check, whether a vector of given values `x` lie within a defined range (or outside respectively). The values can be numbers, text or dates. Ordered factors are supported.

**Usage**

```r
x %()% rng
x %()% rng
x %[]()% rng
x %[]()% rng
x %[]()% rng
x %[]()% rng
x %()% rng
x %()% rng
x %()% rng
x %()% rng
```

**Arguments**

- `x` is a variable with at least ordinal scale, usually a numeric value, but can be an ordered factor or a text as well. Texts would be treated alphabetically.
- `rng` is a vector of two values or a matrix with 2 columns, defining the minimum and maximum of the range for `x`. If `rng` is a matrix, `x` or `rng` will be recycled.

**Details**

The between operators basically combine two conditional statements into one and simplify so the query process. They are merely a wrapper for: `x >= rng[1] & x <= rng[2]`, where the round bracket ( means "strictly greater than >" and the square bracket [ means ">=". Numerical values of `x` will be handled by C-code, which is significantly faster than two comparisons in R (especially when `x` is huge). %]% is the negation of %()%, meaning all values lying outside the given range. Elements on the limits will return TRUE.

Both arguments will be recycled to the highest dimension, which is either the length of the vector or the number of rows of the matrix.

See also the routines used to check, whether two ranges overlap (Overlap, Interval).

**Value**

A logical vector of the same length as `x`.

c(2,3) %[]% cbind(1:4,2:5)
Description

Compute confidence intervals for binomial proportions following the most popular methods. (Wald, Wilson, Agresti-Coull, Jeffreys, Clopper-Pearson etc.)

Usage

BinomCI(x, n, conf.level = 0.95, sides = c("two.sided", "left", "right"),
    method = c("wilson", "wald", "agresti-coull", "jeffreys",
        "modified wilson", "wilsoncc","modified jeffreys",
        "clopper-pearson", "arcsine", "logit", "witting", "pratt"),
    rand = 123)

Arguments

x number of successes.

n number of trials.

conf.level a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.

sides a character string specifying which method to use; this can be one out of: "wald", "wilson","wilsoncc","agresti-coull","jeffreys","modified wilson", "modified jeffreys","clopper-pearson","arcsine","logit","witting" or "pratt". Defaults to "wilson". Abbreviation of method are accepted. See details.

method rand seed for random number generator; see details.

Details

All arguments are being recycled.

The **Wald** interval is obtained by inverting the acceptance region of the Wald large-sample normal test.

The **Wilson** interval, which is the default, was introduced by Wilson (1927) and is the inversion of the CLT approximation to the family of equal tail tests of \( p = p_0 \). The Wilson interval is recommended by Agresti and Coull (1998) as well as by Brown et al (2001).

The **Agresti-Coull** interval was proposed by Agresti and Coull (1998) and is a slight modification of the Wilson interval. The Agresti-Coull intervals are never shorter than the Wilson intervals; cf. Brown et al (2001).

The **Jeffreys** interval is an implementation of the equal-tailed Jeffreys prior interval as given in Brown et al (2001).
The **modified Wilson** interval is a modification of the Wilson interval for \( x \) close to 0 or \( n \) as proposed by Brown et al (2001).

The **Wilson cc** interval is a modification of the Wilson interval adding a continuity correction term.

The **modified Jeffreys** interval is a modification of the Jeffreys interval for \( x = 0 \) \( x = 1 \) and \( x = n-1 \) \( x = n \) as proposed by Brown et al (2001).

The **Clopper-Pearson** interval is based on quantiles of corresponding beta distributions. This is sometimes also called exact interval.

The **arcsine** interval is based on the variance stabilizing distribution for the binomial distribution.

The **logit** interval is obtained by inverting the Wald type interval for the log odds.

The **Pratt interval** is obtained by extremely accurate normal approximation. (Pratt 1968)

Some approaches for the confidence intervals can potentially yield negative results or values beyond 1. These would be reset such as not to exceed the range of \([0, 1]\).

And now, which interval should we use? The Wald interval often has inadequate coverage, particularly for small \( n \) and values of \( p \) close to 0 or 1. Conversely, the Clopper-Pearson Exact method is very conservative and tends to produce wider intervals than necessary. Brown et al. recommends the Wilson or Jeffreys methods for small \( n \) and Agresti-Coul, Wilson, or Jeffreys, for larger \( n \) as providing more reliable coverage than the alternatives. Also note that the point estimate for the Agresti-Coul method is slightly larger than for other methods because of the way this interval is calculated.

**Value**

A vector with 3 elements for estimate, lower confidence intervall and upper for the upper one.

**Note**

The base of this function was `binomCI()` in the `SLmisc` package. In the meantime the code has been updated on several occasions and has undergone some additions and bugfixes.

Examples

```r
BinomCI(x=37, n=43, method=c("wald", "wilson", "agresti-coull", "jeffreys", "modified wilson", "modified jeffreys", "clopper-pearson", "arcsine", "logit", "witting", "pratt")

# the confidence interval computed by binom.test
# corresponds to the Clopper-Pearson interval
BinomCI(x=42, n=43, method="clopper-pearson")
binom.test(x=42, n=43)$conf.int

# all arguments are being recycled:
BinomCI(x=c(42, 35, 23, 22), n=43, method="wilson")
BinomCI(x=c(42, 35, 23, 22), n=c(50, 60, 70, 80), method="jeffreys")
```

---

**BinomDiffCI**  
*Confidence Interval for a Difference of Binomials*

**Description**

Several confidence intervals for the difference between proportions are available, but they can produce markedly different results. Traditional approaches, such as the Wald interval do not perform well unless the sample size is large. Better intervals are available. These include the Agresti/Caffo method (2000), Newcombe Score method (1998) and a more computing intensive ones as by Miettinen and Nurminen (1985) or Mee (1984).

**Usage**

```r
BinomDiffCI(x1, n1, x2, n2, conf.level = 0.95, sides = c("two.sided","left","right"), method = c("wald", "waldcc", "ac", "score", "scorecc", "mn", "mee", "blj", "ha", "beal"))
```
Arguments

- **x1** number of successes for the first group.
- **n1** number of trials for the first group.
- **x2** number of successes for the second group.
- **n2** number of trials for the second group.
- **conf.level** confidence level, defaults to 0.95.
- **sides** a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.
- **method** one of "wald", "waldcc", "ac", "score", "scorecc", "mn", "mee", "blj", "ha", "beal".

Details

All arguments are being recycled.

We estimate the difference between proportions using the sample proportions:

\[ \hat{\delta} = \hat{p}_1 - \hat{p}_2 = \frac{x_1}{n_1} - \frac{x_2}{n_2} \]

The traditional Wald confidence interval for the difference of two proportions \( \delta \) is based on the asymptotic normal distribution of \( \hat{\delta} \).

The Corrected Wald interval uses a continuity correction included in the test statistic. The continuity correction is subtracted from the numerator of the test statistic if the numerator is greater than zero; otherwise, the continuity correction is added to the numerator. The value of the continuity correction is \((1/n_1 + 1/n_2)/2\).

The Agresti-Caffo (code "ac") is equal to the Wald interval with the adjustment according to Agresti, Caffo (2000) for difference in proportions and independent samples. It adds 1 to x1 and x2 and adds 2 to n1 and n2 and performs surprisingly well.

Newcombe (code "scorecc") proposed a confidence interval for the difference based on the Wilson score confidence interval for a single proportion. A variant uses a continuity correction for the Wilson interval (code "scorecc").

Miettinen and Nurminen showed that the restricted maximum likelihood estimates for \( p_1 \) and \( p_2 \) can be obtained by solving a cubic equation and gave unique closed-form expressions for them. The Miettinen-Nurminen confidence interval is returned with code "mn".

The Mee (code "mee") interval proposed by Mee (1984) and Farrington-Manning (1990) is using the same maximum likelihood estimators as Miettinen-Nurminen but with another correcting factor.

The Brown, Li's Jeffreys (code "blj") interval was proposed by Brown, Li's Jeffreys (2005).

The Hauck-Anderson (code "ha") interval was proposed by Hauck-Anderson (1986).

The Beal (code "beal") interval is described in Beal (1987).

Some approaches for the confidence intervals can potentially yield negative results or values beyond [-1, 1]. These would be reset such as not to exceed the range of [-1, 1].

Which of the methods to use is currently still the subject of lively discussion and has not yet been conclusively clarified. See e.g. Fagerland (2011).
Value

A vector with 3 elements for estimate, lower confidence intervall and upper for the upper one.

```
Confidence Intervals for the Ratio of Binomial and Multinomial Proportions

Description

A number of methods have been developed for obtaining confidence intervals for the ratio of two binomial proportions. These include the Wald/Katz-log method (Katz et al. 1978), adjusted-log (Walter 1975, Pettigrew et al. 1986), Koopman asymptotic score (Koopman 1984), Inverse hyperbolic sine transformation (Newman 2001), the Bailey method (Bailey 1987), and the Noether (1957) procedure. Koopman results are found iteratively for most intervals using root finding.

Usage

BinomRatioCI(x1, n1, x2, n2, conf.level = 0.95, method = "katz.log", bonf = FALSE, tol = .Machine$double.eps^0.25, R = 1000, r = length(x1))

Arguments

- x1: The ratio numerator number of successes. A scalar or vector.
- n1: The ratio numerator number of trials. A scalar or vector of length(y1)
- x2: The ratio denominator number of successes. A scalar or vector of length(y1)
- n2: The ratio denominator number of trials. A scalar or vector of length(y1)
- conf.level: The level of confidence, i.e. 1 - P(type I error).
- method: Confidence interval method. One of "adj.log", "bailey", "boot", "katz.log", "koopman", "sinh-1" or "noether". Partial distinct names can be used.
- bonf: Logical, indicating whether or not Bonferroni corrections should be applied for simultaneous inference if y1, y2; n1 and n2 are vectors.
- tol: The desired accuracy (convergence tolerance) for the iterative root finding procedure when finding Koopman intervals. The default is taken to be the smallest positive floating-point number of the workstation implementing the function, raised to the 0.25 power, and will normally be approximately 0.0001.
- R: If method "boot" is chosen, the number of bootstrap iterations.
- r: The number of ratios to which family-wise inferences are being made. Assumed to be length(y1).

Details

Let \( Y_1 \) and \( Y_2 \) be multinomial random variables with parameters \( n_1, \pi_{1i}, \) and \( n_2, \pi_{2i}, \) respectively; where \( i = \{1, 2, 3, \ldots, r\} \). This encompasses the binomial case in which \( r = 1 \). We define the true selection ratio for the \( i \)th resource of \( r \) total resources to be:

\[
\theta_i = \frac{\pi_{1i}}{\pi_{2i}}
\]
where \( \pi_{1i} \) and \( \pi_{2i} \) represent the proportional use and availability of the \( i \)th resource, respectively. Note that if \( r = 1 \) the selection ratio becomes relative risk. The maximum likelihood estimators for \( \pi_{1i} \) and \( \pi_{2i} \) are the sample proportions:

\[
\hat{\pi}_{1i} = \frac{y_{1i}}{n_1},
\]

and

\[
\hat{\pi}_{2i} = \frac{y_{2i}}{n_2},
\]

where \( y_{1i} \) and \( y_{2i} \) are the observed counts for use and availability for the \( i \)th resource. The estimator for \( \theta_i \) is:

\[
\hat{\theta}_i = \frac{\hat{\pi}_{1i}}{\hat{\pi}_{2i}}.
\]

Method | Algorithm
--- | ---
Katz-log | \( \hat{\theta}_i \times \exp(\pm z_1 - \alpha/2\hat{\sigma}_W), \)
where \( \hat{\sigma}_W^2 = \frac{(1-\hat{\pi}_{1i})}{\pi_{1i}n_1} + \frac{(1-\hat{\pi}_{2i})}{\pi_{2i}n_2}. \)

Adjusted-log | \( \hat{\theta}_{Ai} \times \exp(\pm z_1 - \alpha/2\hat{\sigma}_A), \)
where \( \hat{\theta}_{Ai} = \frac{y_{1i}+0.5/n_1+0.5}{y_{1i}+0.5/n_2+0.5}, \)
\( \hat{\sigma}_A^2 = \frac{1}{y_{1i}+0.5} - \frac{1}{n_1+0.5} + \frac{1}{y_{2i}+0.5} - \frac{1}{n_2+0.5}. \)

Bailey | \( \hat{\theta}_i \left[ \frac{1}{\pm z_1 - (\alpha/2)(\hat{\pi}_{1i}^3/y_{1i} + \hat{\pi}_{2i}^3/y_{2i} - z_1 - (\alpha/2)^2 \hat{\pi}_{1i}^2 \hat{\pi}_{2i}^2/9y_{1i}y_{2i})^{1/2}/3 \right], \)
where \( \pi_{1i}' = 1 - \hat{\pi}_{1i}, \) and \( \hat{\pi}_{2i}' = 1 - \hat{\pi}_{2i}. \)

Inv. hyperbolic sine | \( \ln(\hat{\theta}_i) \pm \left[ 2\sinh^{-1}\left( \frac{z_{1-\alpha/2}}{2} \right) \sqrt{\frac{1}{y_{1i}} - \frac{1}{n_1} + \frac{1}{y_{2i}} - \frac{1}{n_2}} \right]. \)

Koopman | Find \( X^2(\theta_0) = \chi^2(1 - \alpha), \) where
\( \tilde{\pi}_{1i} = \theta_0(n_1+y_{2i})+y_{1i}+n_2-\left[\theta_0(n_1+y_{2i})+y_{1i}+n_2\right]^2-4\theta_0(n_1+n_2)(y_{1i}+y_{2i})0.5, \)
\( \tilde{\pi}_{2i} = \frac{\hat{\pi}_{1i}}{\hat{\theta}_0}, \) and \( X^2(\theta_0) = \frac{(y_{1i}-n_1\hat{\pi}_{1i})^2}{n_1(1-\hat{\pi}_{1i})} \left\{ 1 + \frac{n_1(\theta_0-\hat{\pi}_{1i})}{n_2(1-\hat{\pi}_{1i})} \right\}. \)

Noether | \( \hat{\theta}_i \pm z_1 - \alpha/2\hat{\sigma}_N, \)
where \( \hat{\sigma}_N^2 = \hat{\theta}_i^2 \left( \frac{1}{y_{1i}} - \frac{1}{n_1} + \frac{1}{y_{2i}} - \frac{1}{n_2} \right). \)

Exception handling strategies are generally necessary in the cases \( y_1 = 0, n_1 = y_1, y_2 = 0, \) and \( n_2 = y_2 \) (see Aho and Bowyer, in review).

The bootstrap method currently employs percentile confidence intervals.

**Value**

Returns a list of class = "ci". Default output is a matrix with the point and interval estimate.

**BinTree**

*Binary Tree*

Description

Create a binary tree of a given number of nodes n. Can be used to organize a sorted numeric vector as a binary tree.
BinTree

Usage

\texttt{BinTree(n)}

\texttt{PlotBinTree(x, main="Binary tree", horiz=FALSE, cex=1.0, col=1, ...)}

Arguments

\begin{itemize}
  \item \texttt{n} integer, size of the tree
  \item \texttt{x} numeric vector to be organized as binary tree.
  \item \texttt{main} main title of the plot.
  \item \texttt{horiz} logical, should the plot be oriented horizontally or vertically. The latter is default.
  \item \texttt{cex} character extension factor for the labels.
  \item \texttt{col} color of the linesegments of the plot.
  \item \ldots the dots are sent to Canvas.
\end{itemize}

Details

If we index the nodes of the tree as 1 for the top, 2–3 for the next horizontal row, 4–7 for the next, \ldots then the parent-child traversal becomes particularly easy. The basic idea is that the rows of the tree start at indices 1, 2, 4, \ldots .

\texttt{BinTree(13)} yields the vector \texttt{c(8, 4, 9, 2, 10, 5, 11, 1, 12, 6, 13, 3, 7)} meaning that the smallest element will be in position 8 of the tree, the next smallest in position 4, etc.

Value

an integer vector of length \texttt{n}

Author(s)

Andri Signorell \texttt{<andri@signorell.net>} (plot)

Examples

\texttt{BinTree(12)}

\begin{verbatim}
x <- sort(sample(100, 24))
z <- PlotBinTree(x, cex=0.8)
# Plot example - Titanic data, for once from a somewhat different perspective
\end{verbatim}

\texttt{tab <- apply(Titanic, c(2,3,4), sum)}
\texttt{cprob <- c(1, prop.table(apply(tab, 1, sum)), as.vector(aperm(prop.table(apply(tab, c(1,2), sum), 1), c(2, 1))))}
\texttt{as.vector(aperm(prop.table(tab, c(1,2)), c(3,2,1)))}
\texttt{)}
PlotBinTree(round(cprob[BinTree(length(cprob))],2), horiz=TRUE, cex=0.8, 
main="Titanic")
text(c("sex","age","survived"), y=0, x=c(1,2,3)+1)

---

**BootCI**

**Simple Bootstrap Confidence Intervals**

### Description

Convenience wrapper for calculating bootstrap confidence intervals for univariate and bivariate statistics.

### Usage

```r
BootCI(x, y = NULL, FUN, ..., bci.method = c("norm", "basic", "stud", "perc", "bca"),
conf.level = 0.95, sides = c("two.sided", "left", "right"), R = 999)
```

### Arguments

- **x**  
  a (non-empty) numeric vector of data values.

- **y**  
  NULL (default) or a vector with compatible dimensions to `x`, when a bivariate statistic is used.

- **FUN**  
  the function to be used

- **bci.method**  
  A vector of character strings representing the type of intervals required. The value should be any subset of the values "norm", "basic", "stud", "perc", "bca", as it is passed on as method to `boot.ci`.

- **conf.level**  
  confidence level of the interval.

- **sides**  
  a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a `t.test`.

- **...**  
  further arguments are passed to the function `FUN`.

- **R**  
  The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case `R` would be a vector of integers where each component gives the number of resamples from each of the rows of weights.

### Value

a named numeric vector with 3 elements:

- **<FUN>**  
  the specific estimate, as calculated by `FUN`

- **lwr.ci**  
  lower bound of the confidence interval

- **upr.ci**  
  upper bound of the confidence interval
BoxCox

BootCI(d.pizza$temperature, FUN=Skew, na.rm=TRUE, bci.method="basic")

BootCI(d.pizza$operator, d.pizza$area, FUN=CramerV)

spearman <- function(x,y) cor(x, y, method="spearman", use="p")
BootCI(d.pizza$temperature, d.pizza$delivery_min, FUN=spearman)
```

---

BoxCox

Box Cox Transformation

Description

BoxCox() returns a transformation of the input variable using a Box-Cox transformation.
BoxCoxInv() reverses the transformation.

Usage

```r
BoxCox(x, lambda)
BoxCoxInv(x, lambda)
```

Arguments

- `x` a numeric vector
- `lambda` transformation parameter

Details

The Box-Cox transformation is given by

\[ f_\lambda(x) = \begin{cases} 
  x^{\lambda - 1} & \text{for } \lambda \neq 0 \\
  \log(x) & \text{for } \lambda = 0 
\end{cases} \]

Value

a numeric vector of the same length as `x`. 
Note

These two functions are borrowed from `library(forecast)`.

x <- rlnorm(500, 3, 2)

par(mfrow=c(2,2))
qqnorm(x, main="Lognormal")
qqnorm(BoxCox(x, 1/2), main="BoxCox(lambda=0.5)")
qqnorm(BoxCox(x, 0), main="BoxCox(lambda=0)")
PlotFdist(BoxCox(x, 0))
bx <- BoxCox(x, lambda = BoxCoxLambda(x) )
```

---

**BoxCoxLambda**

Automatic Selection of Box Cox Transformation Parameter

Description

An automatic selection of the Box Cox transformation parameter is estimated with two methods. Guerrero’s (1993) method yields a lambda which minimizes the coefficient of variation for subseries of \( x \). For method "loglik", the value of lambda is chosen to maximize the profile log likelihood of a linear model fitted to \( x \). For non-seasonal data, a linear time trend is fitted while for seasonal data, a linear time trend with seasonal dummy variables is used.

Usage

`BoxCoxLambda(x, method = c("guerrero", "loglik"), lower = -1, upper = 2)`
Arguments

- **x**: a numeric vector or time series
- **method**: method to be used in calculating lambda. Can be either "guerrero" (default) or "loglik".
- **lower**: lower limit for possible lambda values, default is -1.
- **upper**: upper limit for possible lambda values, default is 2.

Value

- a number indicating the Box-Cox transformation parameter.

Note

This function was previously published as BoxCox.lambda() in the forecast package and has been integrated here without logical changes.

- BoxCox

Examples

```r
lambda <- BoxCoxLambda(AirPassengers, lower=0)
```

Description

BoxedText draws the strings given in the vector labels at the coordinates given by x and y, surrounded by a rectangle.
Usage

BoxedText(x, y = NULL, labels = seq_along(x), adj = NULL, pos = NULL, offset = 0.5,
          vfont = NULL, cex = 1, txt.col = NULL, font = NULL, srt = 0,
          xpad = 0.2, ypad = 0.2, density = NULL, angle = 45, col = "white",
          border = par("fg"), lty = par("lty"), lwd = par("lwd"), ...)

Arguments

- **x, y** numeric vectors of coordinates where the text labels should be written. If the length of x and y differs, the shorter one is recycled.
- **labels** a character vector or expression specifying the text to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by as.character. If labels is longer than x and y, the coordinates are recycled to the length of labels.
- **adj** The value of adj determines the way in which text strings are justified. A value of 0 produces left-justified text, 0.5 (the default) centered text and 1 right-justified text. (Any value in [0, 1] is allowed, and on most devices values outside that interval will also work.) Note that the adj argument of text also allows adj = c(x, y) for different adjustment in x- and y- directions.
- **pos** a position specifier for the text. If specified this overrides any adj value given. Values of 1, 2, 3 and 4, respectively indicate positions below, to the left of, above and to the right of the specified coordinates.
- **offset** when pos is specified, this value gives the offset of the label from the specified coordinate in fractions of a character width.
- **vfont** NULL for the current font family, or a character vector of length 2 for Hershey vector fonts. The first element of the vector selects a typeface and the second element selects a style. Ignored if labels is an expression.
- **cex** numeric character expansion factor; multiplied by par("cex") yields the final character size. NULL and NA are equivalent to 1.0.
- **txt.col, font** the color and (if vfont = NULL) font to be used, possibly vectors. These default to the values of the global graphical parameters in par().
- **srt** The string rotation in degrees.
- **xpad, ypad** The proportion of the rectangles to the extent of the text within.
- **density** the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. A zero value of density means no shading lines whereas negative values (and NA) suppress shading (and so allow color filling).
- **angle** angle (in degrees) of the shading lines.
- **col** color(s) to fill or shade the rectangle(s) with. The default NA (or also NULL) means do not fill, i.e., draw transparent rectangles, unless density is specified.
- **border** color for rectangle border(s). The default is par("fg"). Use border = NA to omit borders (this is the default). If there are shading lines, border = TRUE means use the same colour for the border as for the shading lines.
- **lty** line type for borders and shading; defaults to "solid".
Description

Calculates the Breslow-Day test of homogeneity for a $2 \times 2 \times k$ table, in order to investigate if all $k$ strata have the same OR. If OR is not given, the Mantel-Haenszel estimate is used.

Usage

BreslowDayTest(x, OR = NA, correct = FALSE)

Arguments

- **x**: a $2 \times 2 \times k$ table.
- **OR**: the odds ratio to be tested against. If left undefined (default) the Mantel-Haenszel estimate will be used.
- **correct**: If TRUE, the Breslow-Day test with Tarone’s adjustment is computed, which subtracts an adjustment factor to make the resulting statistic asymptotically chi-square.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

SpreadOut, similar function in package plotrix boxed.labels (lacking rotation option)
Details

For the Breslow-Day test to be valid, the sample size should be relatively large in each stratum, and at least 80% of the expected cell counts should be greater than 5. Note that this is a stricter sample size requirement than the requirement for the Cochran-Mantel-Haenszel test for tables, in that each stratum sample size (not just the overall sample size) must be relatively large. Even when the Breslow-Day test is valid, it might not be very powerful against certain alternatives, as discussed in Breslow and Day (1980).

Alternatively, it might be better to cast the entire inference problem into the setting of a logistic regression model. Here, the underlying question of the Breslow-Day test can be answered by investigating whether an interaction term with the strata variable is necessary (e.g. using a likelihood ratio test using the `anova` function).

---

BreuschGodfreyTest  Breusch-Godfrey Test

**Description**

BreuschGodfreyTest performs the Breusch-Godfrey test for higher-order serial correlation.

**Usage**

BreuschGodfreyTest(formula, order = 1, order.by = NULL, type = c("Chisq", "F"),
                   data = list(), fill = 0)

**Arguments**

- **formula**: a symbolic description for the model to be tested (or a fitted "lm" object).
- **order**: integer. maximal order of serial correlation to be tested.
- **order.by**: Either a vector z or a formula with a single explanatory variable like ~ z. The observations in the model are ordered by the size of z. If set to NULL (the default) the observations are assumed to be ordered (e.g., a time series).
- **type**: the type of test statistic to be returned. Either "Chisq" for the Chi-squared test statistic or "F" for the F test statistic.
- **data**: an optional data frame containing the variables in the model. By default the variables are taken from the environment which BreuschGodfreyTest is called from.
- **fill**: starting values for the lagged residuals in the auxiliary regression. By default 0 but can also be set to NA.
Details

Under $H_0$ the test statistic is asymptotically Chi-squared with degrees of freedom as given in parameter. If type is set to "F" the function returns a finite sample version of the test statistic, employing an $F$ distribution with degrees of freedom as given in parameter.

By default, the starting values for the lagged residuals in the auxiliary regression are chosen to be 0 (as in Godfrey 1978) but could also be set to NA to omit them.

BreuschGodfreyTest also returns the coefficients and estimated covariance matrix from the auxiliary regression that includes the lagged residuals. Hence, CoefTest (package: RegClassTools) can be used to inspect the results. (Note, however, that standard theory does not always apply to the standard errors and t-statistics in this regression.)

Value

A list with class "BreuschGodfreyTest" inheriting from "htest" containing the following components:

- statistic: the value of the test statistic.
- p.value: the p-value of the test.
- parameter: degrees of freedom.
- method: a character string indicating what type of test was performed.
- data.name: a character string giving the name(s) of the data.
- coefficients: coefficient estimates from the auxiliary regression.
- vcov: corresponding covariance matrix estimate.

Note

This function was previously published as bgtest in the lmtest package and has been integrated here without logical changes.

### Examples

```r
## Generate a stationary and an AR(1) series
x <- rep(c(1, -1), 50)
y1 <- 1 + x + rnorm(100)

## Perform Breusch-Godfrey test for first-order serial correlation:
BreuschGodfreyTest(y1 ~ x)

## or for fourth-order serial correlation
BreuschGodfreyTest(y1 ~ x, order = 4)

## Compare with Durbin-Watson test results:
DurbinWatsonTest(y1 ~ x)

y2 <- filter(y1, 0.5, method = "recursive")
BreuschGodfreyTest(y2 ~ x)
```

---

**BrierScore**

*Brier Score for Assessing Prediction Accuracy*

#### Description

Calculate Brier score for assessing the quality of the probabilistic predictions of binary events.

#### Usage

```r
BrierScore(...)
```

- **S3 method for class 'glm'**
  ```r
  BrierScore(x, scaled = FALSE, ...)
  ```

- **Default S3 method:**
  ```r
  BrierScore(resp, pred, scaled = FALSE, ...)
  ```

#### Arguments

- **x**
  a glm object

- **resp**
  the response variable

- **pred**
  the predicted values

- **scaled**
  logical, defining if scaled or not. Default is FALSE.

- **...**
  further arguments to be passed to other functions.
Details

The Brier score is a proper score function that measures the accuracy of probabilistic predictions. It is applicable to tasks in which predictions must assign probabilities to a set of mutually exclusive discrete outcomes. The set of possible outcomes can be either binary or categorical in nature, and the probabilities assigned to this set of outcomes must sum to one (where each individual probability is in the range of 0 to 1).

It’s calculated as

$$\frac{1}{n} \cdot \sum_{i=1}^{n} (p_i - o_i)^2$$

where $p_i$ is the predicted probability and $o_i$ is the observed value out of $(0, 1)$.

The lower the Brier score is for a set of predictions, the better the predictions are calibrated. Note that the Brier score, in its most common formulation, takes on a value between zero and one, since this is the largest possible difference between a predicted probability (which must be between zero and one) and the actual outcome (which can take on values of only 0 and 1). (In the original (1950) formulation of the Brier score, the range is double, from zero to two.)

Value

a numeric value

Examples

```r
r.glm <- glm(Survived ~ ., data=Untable(Titanic), family=binomial)
BrierScore(r.glm)
```
**BubbleLegend**

*Add a Legend to a Bubble Plot*

**Description**

Add a legend for bubbles to a bubble plot.

**Usage**

```r
BubbleLegend(x, y = NULL, area, cols, labels = NULL, cols.lbl = "black",
              width = NULL, xjust = 0, yjust = 1, inset = 0, border = "black",
              frame = TRUE, adj = c(0.5, 0.5), cex = 1, cex.names = 1,
              bg = NULL, ...)
```

**Arguments**

- `x`: the left x-coordinate to be used to position the legend. See 'Details'.
- `y`: the top y-coordinate to be used to position the legend. See 'Details'.
- `area`: the area(s) for the bubbles in bubble legend.
- `cols`: the color appearing in the legend.
- `labels`: a vector of labels to be placed at the right side of the legend.
- `cols.lbl`: the textcolor for the labels of the bubbles.
- `width`: the width of the legend.
- `xjust`: how the legend is to be justified relative to the legend x location. A value of 0 means left justified, 0.5 means centered and 1 means right justified.
- `yjust`: the same as `xjust` for the legend y location.
- `inset`: inset distance(s) from the margins as a fraction of the plot region when legend is placed by keyword.
- `border`: defines the border color of each rectangle. Default is none (NA).
- `frame`: defines the border color of the frame around the whole legend. Default is none (NA).
- `adj`: text alignment, horizontal and vertical.
- `cex`: extension factor for the area, default 1.0.
- `cex.names`: character extension for the labels, default 1.0.
- `bg`: the background color for the bubble legend.
- `...`: further arguments are passed to the function `text`. 
Details
The labels are placed in the middle of the legend.

The location of the legend may be specified by setting `x` to a single keyword from the list "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center". This places the legend on the inside of the plot frame at the given location. Partial argument matching is used. The optional inset argument specifies how far the legend is inset from the plot margins. If a single value is given, it is used for both margins; if two values are given, the first is used for x-distance, the second for y-distance. This is the same behaviour as it's implemented in `legend`.

`legend`, `FindColor`, `legend`

Examples

```r
PlotBubble(x=d.pizza$delivery_min, y=d.pizza$temperature, area=d.pizza$price,
  xlab="delivery time", ylab="temperature",
  col=SetAlpha(as.numeric(d.pizza$area)+2, .5), border="darkgrey",
  na.rm=TRUE, main="Price-Bubbles", panel.first=grid())

BubbleLegend("bottomleft", area=c(1500, 1000, 500), frame=TRUE,
  cols=SetAlpha("steelblue",0.5), bg="green",
  radius = c(1, 2.5, 5), labels=c(1500, 1000, 500), cex=0.8,
  cols.lbl=c("yellow", "red","blue"))
```

---

**Canvas**

*Canvas for Geometric Plotting*

Description
This is just a wrapper for creating an empty plot with suitable defaults for plotting geometric shapes.

Usage

```r
Canvas(xlim = NULL, ylim = xlim, main = NULL, xpd = par("xpd"),
  mar=c(5.1,5.1,5.1,5.1), asp = 1, bg = par("bg"), usrbg = "white", ...)
```

Arguments
- `xlim`, `ylim` the xlims and ylims for the plot. Default is c(-1, 1).
- `xpd` expand drawing area, defaults to `par("xpd")`.
- `main` the main title on top of the plot.
set margins. Defaults to c(5.1,5.1,5.1,5.1).

asp numeric, giving the aspect ratio y/x. (See plot.window for details. Default is 1.

bg the background color of the plot, defaults to par("bg"), which usually will be

"white".

usrbg the color of the user space of the plot, defaults to "white".

... additional arguments are passed to the plot() command.

Details

The plot is created with these settings:

asp = 1, xaxt = "n", yaxt = "n", xlab = "", ylab = "", frame.plot = FALSE.

Value

a list of all the previous values of the parameters changed (returned invisibly)

Author(s)

Andri Signorell <andri@signorell.net>

Examples

Canvas(7)

text(0, 0, "Hello world!", cex=5)

Description

Transform cartesian into polar coordinates, resp. to spherical coordinates and vice versa.

Usage

CartToPol(x, y)

PolToCart(r, theta)

CartToSph(x, y, z, up = TRUE)

SphToCart(r, theta, phi, up = TRUE)

Arguments

x, y, z vectors with the xy-coordinantes to be transformed.

r a vector with the radius of the points.

theta a vector with the angle(s) of the points.

phi a vector with the angle(s) of the points.

up logical. If set to TRUE (default) theta is measured from x-y plane, else theta is measured from the z-axis.
Details

Angles are in radians, not degrees (i.e., a right angle is pi/2). Use \texttt{DegToRad} to convert, if you don’t wanna do it by yourself.

All parameters are recycled if necessary.

Value

\texttt{PolToCart} returns a list of \(x\) and \(y\) coordinates of the points.

\texttt{CartToPol} returns a list of \(r\) for the radius and \(theta\) for the angles of the given points.

\end{verbatim}

\section*{CatTable}

\textit{Function to write a table}

\section*{Description}

\texttt{CatTable} helps printing a table, if is has to be broken into multiple rows. Rowlabels will be repeated after every new break.

\section*{Usage}

\texttt{CatTable(tab, wcol, nrepchars, width = getOption("width"))}

\section*{Arguments}

\begin{description}
\item[tab] the rows of a table to be printed, pasted together in one string with constant columnwidth.
\item[wcol] integer, the width of the columns. All columns must have the same width.
\item[nrepchars] integer, the number of characters to be repeated with every break. This is typically the maximum width of the rowlabels.
\item[width] integer, the width of the whole table. Default is the width of the current command window (getOption("width")).
\end{description}

### CCC

**Concordance Correlation Coefficient**

**Description**
Calculates Lin’s concordance correlation coefficient for agreement on a continuous measure.

**Usage**

```r
CCC(x, y, ci = "z-transform", conf.level = 0.95, na.rm = FALSE)
```

**Arguments**

- `x`  
  a vector, representing the first set of measurements.

- `y`  
  a vector, representing the second set of measurements.

- `ci`  
  a character string, indicating the method to be used. Options are z-transform or asymptotic.

- `conf.level`  
  magnitude of the returned confidence interval. Must be a single number between 0 and 1.

- `na.rm`  
  logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.
Details

Computes Lin’s (1989, 2000) concordance correlation coefficient for agreement on a continuous measure obtained by two methods. The concordance correlation coefficient combines measures of both precision and accuracy to determine how far the observed data deviate from the line of perfect concordance (that is, the line at 45 degrees on a square scatter plot). Lin’s coefficient increases in value as a function of the nearness of the data’s reduced major axis to the line of perfect concordance (the accuracy of the data) and of the tightness of the data about its reduced major axis (the precision of the data).

Both x and y values need to be present for a measurement pair to be included in the analysis. If either or both values are missing (i.e. coded NA) then the measurement pair is deleted before analysis.

Value

A list containing the following:

- `rho.c` the concordance correlation coefficient.
- `s.shift` the scale shift.
- `l.shift` the location shift.
- `C.b` a bias correction factor that measures how far the best-fit line deviates from a line at 45 degrees. No deviation from the 45 degree line occurs when C.b = 1. See Lin (1989, page 258).
- `blalt` a data frame with two columns: `mean` the mean of each pair of measurements, `delta` vector y minus vector x.

ylim = c(-140,140))
abline(h = tmp.mean, lty = 1, col = "gray")
```
CentralValue

Obtain statistic of centrality

Description
This function obtains a statistic of centrality of a variable given a sample of its values.

Usage
CentralValue(x, weights = NULL)

Arguments
x a vector of values (the sample).
weights a numerical vector of weights the same length as x giving the weights to use for elements of x.

Details
If the variable is numeric it returns the median of the given sample. if it is a factor it returns the mode. In other cases it tries to convert to a factor and then returns the mode.

Value
A number if the variable is numeric. A string with the name of the most frequent nominal value, otherwise.

PlotPolar

Examples

Clockwise( c(0, pi/4, pi/2, pi))
Closest

*Find the Closest Value*

**Description**

Find the closest value(s) of a number in a vector x. Multiple values will be reported, if the differences are the same.

**Usage**

```
Closest(x, a, which = FALSE, na.rm = FALSE)
```

**Arguments**

- `x`: the vector to be searched in
- `a`: the reference value
- `which`: a logical value defining if the index position or the value should be returned. By default will the value be returned.
- `na.rm`: a logical value indicating whether NA values should be stripped before the computation proceeds.

**Value**

the value or index in x which is closest to a

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

which

**Examples**

```
set.seed(8)
x <- sample(10, size=10, replace=TRUE)

Closest(x, 6)
Closest(x, 6, which=TRUE)

Closest(c(2, 3, 4, 5), 3.5)
```
Description

Return the first element of a vector, not being NA.

Usage

Coalesce(..., method = c("is.na", "is.finite"))

Arguments

... the elements to be evaluated. This can either be a single vector, several vectors of same length, a matrix, a data.frame or a list of vectors (of same length). See examples.

method one out of "is.na" (default) or "is.finite". The "is.na" option allows Inf values to be in the result, the second one eliminates them.

Details

If several vectors are supplied, the evaluation will be elementwise, resp. rowwise if x is a data.frame or a matrix. The first element of the result is the first non NA element of the first elements of all the arguments, the second element of the result is the one of the second elements of all the arguments and so on.

Shorter inputs (of non-zero length) are NOT recycled. The function will bark, if multiple vectors do not all have the same dimension.
The idea is borrowed from SQL. Might sometimes be useful when preparing data in R instead of in SQL.

Value

return a single vector of the first non NA element(s) of the given data structure.

Coalesce(d.frm)
Coalesce(as.list(d.frm))

CochranArmitageTest  Cochran-Armitage Test for Trend

Description

Perform a Cochran Armitage test for trend in binomial proportions across the levels of a single variable. This test is appropriate only when one variable has two levels and the other variable is ordinal. The two-level variable represents the response, and the other represents an explanatory variable with ordered levels. The null hypothesis is the hypothesis of no trend, which means that the binomial proportion is the same for all levels of the explanatory variable.

Usage

CochranArmitageTest(x, alternative = c("two.sided", "increasing", "decreasing"))
CochranArmitageTest

Arguments

x a frequency table or a matrix.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "increasing" or "decreasing". You can specify just the initial letter.

Value

A list of class htest, containing the following components:

statistic the z-statistic of the test.

parameter the dimension of the table.

p.value the p-value for the test.

alternative a character string describing the alternative hypothesis.

method the character string “Cochran-Armitage test for trend”.

data.name a character string giving the names of the data.

---

**CochranQTest**

**Cochran’s Q test**

**Description**

Perform the Cochran’s Q test for unreplicated randomized block design experiments with a binary response variable and paired data.

**Usage**

CochranQTest(y, ...)

## Default S3 method:
CochranQTest(y, groups, blocks, ...)

## S3 method for class 'formula'
CochranQTest(formula, data, subset, na.action, ...)

**Arguments**

- **y**
  - either a numeric vector of data values, or a data matrix.
- **groups**
  - a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
- **blocks**
  - a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
- **formula**
  - a formula of the form y ~ groups | blocks.
- **data**
  - an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula. By default the variables are taken from `environment(formula)`.
- **subset**
  - an optional vector specifying a subset of observations to be used.
- **na.action**
  - a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**
  - further arguments to be passed to or from methods.

**Details**

CochranQTest() can be used for analyzing unreplicated complete block designs (i.e., there is exactly one binary observation in y for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of y is the same in each of the groups.
CochranQTest

If y is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA’s are not allowed in groups or blocks; if y contains NA’s, corresponding blocks are removed.

Note that Cochran’s Q Test is analogue to the Friedman test with 0, 1 coded response. This is used here for a simple implementation.

Value

A list with class htest containing the following components:

- statistic: the value of Cochran’s chi-squared statistic.
- parameter: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- p.value: the p-value of the test.
- method: the character string "Cochran’s Q-Test".
- data.name: a character string giving the names of the data.

Examples

# example in:
# pp. S. 1824

# use expand.grid, xtabs and Untable to create the dataset
d.frm <- Untable(xtabs(c(6,2,6,2,16,4,4,6) ~ .,
   expand.grid(rep(list(c("F","U")), times=3))),
  colnames = LETTERS[1:3])

# rearrange to long shape
d.long <- reshape(d.frm, varying=1:3, times=names(d.frm)[c(1:3)],
   v.names="resp", direction="long")

# after having done the hard work of data organisation, performing the test is a piece of cake....
CochranQTest(resp ~ time | id, data=d.long)
Description

Calculates the coefficient of variation and its confidence limits using the noncentral t-distribution.

Usage

CoefVar(x, ...)

## S3 method for class 'lm'
CoefVar(x, unbiased = FALSE, conf.level = NA, na.rm = FALSE, ...)

## S3 method for class 'aov'
CoefVar(x, unbiased = FALSE, conf.level = NA, na.rm = FALSE, ...)

## Default S3 method:
CoefVar(x, weights = NULL, unbiased = FALSE, conf.level = NA, na.rm = FALSE, ...)

Arguments

x      a (non-empty) numeric vector of data values.
weights a numerical vector of weights the same length as x giving the weights to use for elements of x.
unbiased logical value determining, if a bias correction should be used (see. details). Default is FALSE.
conf.level confidence level of the interval.
na.rm   logical. Should missing values be removed? Defaults to FALSE.
...     further arguments (not used here).

Details

In order for the coefficient of variation to be an unbiased estimate of the true population value, the coefficient of variation is corrected as:

\[ CV_{korr} = CV \cdot \left( 1 - \frac{1}{4 \cdot (n - 1)} + \frac{1}{n} \cdot CV^2 + \frac{1}{2 \cdot (n - 1)^2} \right) \]

Value

if no confidence intervals are requested: the estimate as numeric value (without any name)
else a named numeric vector with 3 elements

est     estimate
CohenD

lower confidence interval
upper confidence interval

```

---

CohenD *Cohen’s Effect Size*

Description
Computes the Cohen’s d and Hedges’g effect size statistics.

Usage
```
CohenD(x, y = NULL, pooled = TRUE, correct = FALSE, conf.level = NA, na.rm = FALSE)
```
Arguments

- **x**: a (non-empty) numeric vector of data values.
- **y**: a (non-empty) numeric vector of data values.
- **pooled**: logical, indicating whether compute pooled standard deviation or the whole sample standard deviation. Default is TRUE.
- **correct**: logical, indicating whether to apply the Hedges correction. (Default: FALSE)
- **conf.level**: confidence level of the interval. Set this to NA, if no confidence intervals should be calculated. (This is the default)
- **na.rm**: logical. Should missing values be removed? Defaults to FALSE.

Value

A numeric vector with 3 elements:

- **d**: the effect size \(d\)
- **lwr.ci**: lower bound of the confidence interval
- **upr.ci**: upper bound of the confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```R
# Create two vectors for price comparison
x <- d.pizza$price[d.pizza$driver=="Carter"]
y <- d.pizza$price[d.pizza$driver=="Miller"]

# Compute Cohen's D with 95% confidence interval
CohenD(x, y, conf.level=0.95, na.rm=TRUE)
```
### Description
Computes the agreement rates Cohen's kappa and weighted kappa and their confidence intervals.

### Usage
```
CohenKappa(x, y = NULL, weights = c("Unweighted", "Equal-Spacing", "Fleiss-Cohen"),
    conf.level = NA, ...)
```

### Arguments
- **x**
  - can either be a numeric vector or a confusion matrix. In the latter case x must be a square matrix.
- **y**
  - NULL (default) or a vector with compatible dimensions to x. If y is provided, `table(x,y,...)` is calculated. In order to get a square matrix, x and y are coerced to factors with synchronized levels. (Note, that the vector interface can not be used together with weights.)
- **weights**
  - either one out of "Unweighted", "Equal-Spacing", "Fleiss-Cohen", which will calculate the weights accordingly, or a user-specified matrix having the same dimensions as x containing the weights for each cell.
- **conf.level**
  - confidence level of the interval. If set to NA (which is the default) no confidence intervals will be calculated.
- **...**
  - further arguments are passed to the function `table`, allowing i.e. to set `useNA`. This refers only to the vector interface.

### Details
Cohen's kappa is the diagonal sum of the (possibly weighted) relative frequencies, corrected for expected values and standardized by its maximum value.

The equal-spacing weights (see Cicchetti and Allison 1971) are defined by

\[ 1 - \frac{|i - j|}{r - 1} \]

\( r \) being the number of columns/rows, and the Fleiss-Cohen weights by

\[ 1 - \frac{(i - j)^2}{(r - 1)^2} \]

The latter attaches greater importance to closer disagreements.

Data can be passed to the function either as matrix or data.frame in x, or as two numeric vectors x and y. In the latter case `table(x,y,...)` is calculated. Thus NAs are handled the same way as `table` does. Note that tables are by default calculated **without** NAs. The specific argument
useNA can be passed via the ... argument. The vector interface \((x, y)\) is only supported for the calculation of unweighted kappa. For 2 factors with different levels we cannot ensure a reproducible construction of a confusion table, which is independent of the order of \(x\) and \(y\). All weights might lead to inconsistent results. Thus the function will raise an error in such cases.

**Value**

if no confidence intervals are requested: the estimate as numeric value

else a named numeric vector with 3 elements

- \(\text{kappa}\) estimate
- \(\text{lwr.ci}\) lower confidence interval
- \(\text{upr.ci}\) upper confidence interval

**CollapseTable**

**Collapse Levels of a Table**

**Description**

Collapse (or re-label) variables in a a contingency table or ftable object by re-assigning levels of the table variables.
Usage

```r
CollapseTable(x, ...)
```

Arguments

- `x` A table or `ftable` object
- `...` A collection of one or more assignments of factors of the table to a list of levels

Details

Each of the `...` arguments must be of the form `variable = levels`, where `variable` is the name of one of the table dimensions, and `levels` is a character or numeric vector of length equal to the corresponding dimension of the table. Missing argument names are allowed and will be interpreted in the order of the dimensions of the table.

Value

A table object (even if the input was an `ftable`), representing the original table with one or more of its factors collapsed or rearranged into other levels.

Author(s)

Michael Friendly <friendly@yorku.ca>, Andri Signorell <andri@signorell.net>

ColorLegend

Add a ColorLegend to a Plot

Description

Add a color legend, an image of a sequence of colors, to a plot.
Usage

ColorLegend(x, y = NULL, cols = rev(heat.colors(100)), labels = NULL,
    width = NULL, height = NULL, horiz = FALSE, xjust = 0, yjust = 1,
    inset = 0, border = NA, frame = NA, cntrlbl = FALSE,
    adj = ifelse(horiz, c(0.5, 1), c(1, 0.5)), cex = 1, ...)

Arguments

x  
the left x-coordinate to be used to position the colorlegend. See 'Details'.
y  
the top y-coordinate to be used to position the colorlegend. See 'Details'.
cols  
the color appearing in the colorlegend.
labels  
a vector of labels to be placed at the right side of the colorlegend.
width  
the width of the colorlegend.
height  
the height of the colorlegend.
horiz  
logical indicating if the colorlegend should be horizontal; default FALSE means vertical alignment.
xjust  
how the colorlegend is to be justified relative to the colorlegend x location. A value of 0 means left justified, 0.5 means centered and 1 means right justified.
yjust  
the same as xjust for the legend y location.
inset  
inset distance(s) from the margins as a fraction of the plot region when colorlegend is placed by keyword.
border  
defines the border color of each rectangle. Default is none (NA).
frame  
defines the border color of the frame around the whole colorlegend. Default is none (NA).
ecntrbl  
defines, whether the labels should be printed in the middle of the color blocks or start at the edges of the colorlegend. Default is FALSE, which will print the extreme labels centered on the edges.
adj  
text alignment, horizontal and vertical.
cex  
character extension for the labels, default 1.0.
...  
further arguments are passed to the function text.

Details

The labels are placed at the right side of the colorlegend and are reparted uniformly between y and y - height.

The location may also be specified by setting x to a single keyword from the list "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center". This places the colorlegend on the inside of the plot frame at the given location. Partial argument matching is used. The optional inset argument specifies how far the colorlegend is inset from the plot margins. If a single value is given, it is used for both margins; if two values are given, the first is used for x-distance, the second for y-distance.
ColToGrey

Convert Colors to Grey/Grayscale

Description

Convert colors to grey/grayscale so that you can see how your plot will look after photocopying or printing to a non-color printer.
Usage

ColToGrey(col)
ColToGray(col)

Arguments

col vector of any of the three kind of R colors, i.e., either a color name (an element of colors()), a hexadecimal string of the form "#rrggbb" or "#rrggbbaa" (see rgb), or an integer i meaning palette()[i]. Non-string values are coerced to integer.

Details

Converts colors to greyscale using the formula grey = 0.3*red + 0.59*green + 0.11*blue. This allows you to see how your color plot will approximately look when printed on a non-color printer or photocopied.

Value

A vector of colors (greys) corresponding to the input colors.

Note

These function was previously published as Col2Grey() in the TeachingDemos package and has been integrated here without logical changes.

Author(s)

Greg Snow <greg.snow@imail.org>

See Also

grey, ColToRgb, dichromat package

Examples

par(mfcol=c(2,2))
tmp <- 1:3
names(tmp) <- c('red','green','blue')

barplot(tmp, col=c('red','green','blue'))
barplot(tmp, col=ColToGrey(c('red','green','blue')))

barplot(tmp, col=c('red','#008100','#3636ff'))
barplot(tmp, col=ColToGrey(c('red','#008100','#3636ff')))

CoToGrey
**ColToHex**  
*Convert a Color or a RGB-color Into Hex String*

**Description**

Convert a color given by name, by its palette index or by rgb-values into a string of the form "#rrggbb" or "#rrggbbaa".

**Usage**

`ColToHex(col, alpha = 1)`

**Arguments**

- `col` vector of any of either a color name (an element of `colors()`), or an integer `i` meaning `palette()[i]`. Non-string values are coerced to integer.
- `alpha` the alpha value to be used. This can be any value from 0 (fully transparent) to 1 (opaque). Default is 1.

**Value**

Returns the colorvalue in #rrggbb" or #rrggbbaa" format. (character)

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

`HexToCol, ColToRgb, colors`

**Examples**

```r
ColToHex(c("lightblue", "salmon"))
x <- ColToRgb("darkmagenta")
x[2,] <- x[2,] + 155
RgbToCol(x)
RgbToHex(c(255,0,0))
```
ColToHsv

Р Color to HSV Conversion

Description
ColToHsv transforms colors from R color into HSV space (hue/saturation/value).

Usage
ColToHsv(col, alpha = FALSE)

Arguments
col       vector of any of the three kind of R colors, i.e., either a color name (an element of colors()), a hexadecimal string of the form "#rrggbbaa", or an integer i meaning palette()[i]. Non-string values are coerced to integer.
alpha     logical value indicating whether alpha channel (opacity) values should be returned.

Details
Converts a color first into RGB an from there into HSV space by means of the functions rgb2hsv and col2rgb.

Value (brightness) gives the amount of light in the color. Hue describes the dominant wavelength. Saturation is the amount of Hue mixed into the color.

An HSV colorspace is relative to an RGB colorspace, which in R is sRGB, which has an implicit gamma correction.

Value
A matrix with a column for each color. The three rows of the matrix indicate hue, saturation and value and are named "h", "s", and "v" accordingly.

Author(s)
Andri Signorell <andri@signorell.net>

See Also
rgb2hsv, ColToRgb

Examples
ColToHsv("peachpuff")

ColToHsv(1:8)
ColToOpaque

Equivalent Opaque Color for Transparent Color

Description

Determine the equivalent opaque RGB color for a given partially transparent RGB color against a background of any color.

Usage

ColToOpaque(col, alpha = NULL, bg = NULL)

Arguments

- col: the color as hex value (use converters below if it’s not available). col and alpha are recycled.
- alpha: the alpha channel, if left to NULL the alpha channels of the colors are used
- bg: the background color to be used to calculate against (default is "white")

Details

Reducing the opacity against a white background is a good way to find usable lighter and less saturated tints of a base color. For doing so, we sometimes need to get the equivalent opaque color for the transparent color.

Value

An named vector with the hexcodes of the opaque colors.

Author(s)

Andri Signorell <andri@signorell.net>

ColToHex, DecToHex, RgbToHex

Examples

cols <- c(SetAlpha("limegreen", 0.4), ColToOpaque(ColToHex("limegreen"), 0.4), "limegreen")
barplot(c(1, 1.2, 1.3), col=cols, panel.first=abline(h=0.4, lwd=10, col="grey35"))
ColToRgb  

**Color to RGB Conversion**

**Description**

R color to RGB (red/green/blue) conversion.

**Usage**

```
ColToRgb(col, alpha = FALSE)
```

**Arguments**

- `col` vector of any of the three kind of R colors, i.e., either a color name (an element of `colors()`), a hexadecimal string of the form "#rrggbb" or "#rrggbbaa", or an integer i meaning `palette()[i]`. Non-string values are coerced to integer.
- `alpha` logical value indicating whether alpha channel (opacity) values should be returned.

**Details**

This is merely a wrapper to `col2rgb`, defined in order to follow this package’s naming conventions.

**Value**

A matrix with a column for each color. The three rows of the matrix indicate red, green and blue value and are named "red", "green", and "blue" accordingly. The matrix might have a 4th row if an alpha channel is requested.

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

`col2rgb`, `RgbToCol`

**Examples**

```
ColToRgb("peachpuff")
ColToRgb(c(blue = "royalblue", reddish = "tomato")) # names kept

ColToRgb(1:8)
```
Description

Wraps text in a character matrix so, that it’s displayed over more than one line.

Usage

ColumnWrap(x, width = NULL)

Arguments

x the matrix with one row
width integer, the width of the columns in characters

Details

A data.frame containing character columns with long texts is often wrapped by columns. This can lead to a loss of overview. ColumnWrap wraps the lines within the columns.

Value

a character matrix

strwrap

Examples

Abstract(d.pizza)
CombPairs

Get All Pairs Out of One or Two Sets of Elements

Description

Returns all combinations of 2 out of the elements in x or x and y (if defined). Combinations of the same elements will be dropped (no replacing).

Usage

CombPairs(x, y = NULL)

Arguments

x         a vector of elements
y         a vector of elements, need not be same dimension as x. If y is not NULL then all combination x and y are returned.

Details

If y = NULL then all combination of 2 out of x are returned.
If y is defined then all combinations of x and y are calculated.

Value

CombPairs returns a data.frame with 2 columns X1 and X2.

Author(s)

Andri Signorell <andri@signorell.net>

CombPairs(which(sapply(d.pizza, IsNumeric)), which(sapply(d.pizza, is.factor)))
**CompleteColumns**  
*Find Complete Columns*

**Description**
Return either the columnnames or a logical vector indicating which columns are complete, i.e., have no missing values.

**Usage**
CompleteColumns(x, which = TRUE)

**Arguments**
- **x**: a data.frame containing the data
- **which**: logical, determining if the names of the variables should be returned or a if a logical vector indicating which columns are complete should be returned.

**Value**
A logical vector specifying which columns have no missing values across the entire sequence.

**ConDisPairs**  
*Concordant and Discordant Pairs*

**Description**
This function counts concordant and discordant pairs for two variables x, y with at least ordinal scale, aggregated in a 2way table. This is the base for many association measures like Goodman Kruskal’s gamma, but also all tau measures.

**Usage**
ConDisPairs(x)
Arguments

x  a 2-dimensional table. The column and the row order must be the logical one.

Details

The code is so far implemented in R (O(n^2)) and therefore slow for large sample sizes (>5000). An O(n log(n)) implementation is on track.

Value

a list with the number of concordant pairs, the number of discordant pairs and the matrix

Author(s)

Andri Signorell <andri@signorell.net>

Association measures:

Examples

```r
tab <- as.table(rbind(c(26,26,23,18,9),c(6,7,9,14,23)))
ConDisPairs(tab)
```

Description

Calculates a cross-tabulation of observed and predicted classes with associated statistics.
**Usage**

```
Conf(x, ...)  
## S3 method for class 'table'
Conf(x, pos = NULL, ...)  
## S3 method for class 'matrix'
Conf(x, pos = NULL, ...)  
## Default S3 method:
Conf(x, ref, pos = NULL, na.rm = TRUE, ...)  
## S3 method for class 'rpart'
Conf(x, ...)  
## S3 method for class 'multinom'
Conf(x, ...)  
## S3 method for class 'glm'
Conf(x, cutoff = 0.5, ...)  
## S3 method for class 'randomForest'
Conf(x, ...)  
## S3 method for class 'svm'
Conf(x, ...)  
## S3 method for class 'regr'
Conf(x, ...)  
## S3 method for class 'Conf'
plot(x, main = "Confusion Matrix", ...)  
## S3 method for class 'Conf'
print(x, digits = max(3, getOption("digits") - 3), ...)  
Sens(x, ...)  
Spec(x, ...)  
```

**Arguments**

- **x**
  
  A vector, normally a factor, of predicted classes or an object of following classes `rpart`, `randomForest`, `svm`, `C50`, `glm`, `multinom`, `reg`, `lda`, `qda` or `table`, resp. `matrix`. When a model is given, the predicted classes will be determined. A table or a matrix will be interpreted as a confusion matrix.

- **ref**
  
  A vector, normally a factor, of classes to be used as the reference. This is ignored if `x` is a `table` or `matrix`.

- **pos**
  
  A character string that defines the factor level corresponding to the "positive" results. Will be ignored for a \( n \times n \) table \( n > 2 \).

- **cutoff**
  
  Used in logit models. The cutoff for changing classes.

- **main**
  
  Overall title for the plot.

- **digits**
  
  Controls the number of digits to print.
na.rm a logical value indicating whether or not missing values should be removed. Defaults to FALSE.

... further arguments to be passed to or from methods.

Details

The functions require the factors to have the same levels.

For two class problems, the sensitivity, specificity, positive predictive value and negative predictive value is calculated using the positive argument. Also, the prevalence of the "event" is computed from the data (unless passed in as an argument), the detection rate (the rate of true events also predicted to be events) and the detection prevalence (the prevalence of predicted events).

Suppose a $2 \times 2$ table with notation

<table>
<thead>
<tr>
<th></th>
<th>Reference</th>
<th>Predicted Event</th>
<th>No Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>A</td>
<td>B</td>
<td></td>
</tr>
<tr>
<td>No Event</td>
<td>C</td>
<td>D</td>
<td></td>
</tr>
</tbody>
</table>

The formulas used here are:

\[
\text{Sensitivity} = \frac{A}{(A+C)}
\]

\[
\text{Specificity} = \frac{D}{(B+D)}
\]

\[
\text{Prevalence} = \frac{(A+C)}{(A+B+C+D)}
\]

\[
\text{PPV} = \frac{(\text{sensitivity}*\text{Prevalence})}{((\text{sensitivity}*\text{Prevalence})+(1-\text{specificity})*(1-\text{Prevalence}))}
\]

\[
\text{NPV} = \frac{(\text{specificity}*(1-\text{Prevalence}))}{(((1-\text{sensitivity})*\text{Prevalence})+(\text{specificity})*(1-\text{Prevalence}))}
\]

\[
\text{Detection Rate} = \frac{A}{(A+B+C+D)}
\]

\[
\text{Detection Prevalence} = \frac{(A+B)}{(A+B+C+D)}
\]

\[
\text{F-val Accuracy} = 2/(1/\text{PPV} + 1/\text{Sensitivity})
\]

\[
\text{Matthews Cor. - Coef} = (A * D - B * C) / sqrt((A+B)*(A+C)*(D+B)*(D+C))
\]

See the references for discussions of the first five formulas.

For more than two classes, these results are calculated comparing each factor level to the remaining levels (i.e. a "one versus all" approach).

The overall accuracy and unweighted Kappa statistic are calculated. A p-value from McNemar’s test is also computed using \texttt{mcnemar.test} (which can produce NA values with sparse tables).

The overall accuracy rate is computed along with a 95 percent confidence interval for this rate (using \texttt{BinomCI}) and a one-sided test to see if the accuracy is better than the "no information rate," which is taken to be the largest class percentage in the data.

The sensitivity is defined as the proportion of positive results out of the number of samples which were actually positive. When there are no positive results, sensitivity is not defined and a value of NA is returned. Similarly, when there are no negative results, specificity is not defined and a value of NA is returned. Similar statements are true for predictive values.

Confidence intervals for sensitivity, specificity etc. could be calculated as binomial confidence intervals (see \texttt{BinomCI}). \texttt{BinomCI(A,A+C)} yields the ci for sensitivity.
Value

- table: the results of table on data and reference
- positive: the positive result level
- overall: a numeric vector with overall accuracy and Kappa statistic values
- byClass: the sensitivity, specificity, positive predictive value, negative predictive value, prevalence, detection rate and detection prevalence for each class. For two class systems, this is calculated once using the positive argument

**ConnLines**

*Add Connection Lines to a Barplot*

**Description**

Add connection lines to a stacked barplot (beside = TRUE is not supported). The function expects exactly the same arguments, that were used to create the barplot.

**Usage**

```
ConnLines(..., col = 1, lwd = 1, lty = "solid", xalign = c("mar","mid"))
```

**Arguments**

- `...` the arguments used to create the barplot. (The dots are sent directly to barplot).
- `col` the line color of the connection lines. Defaults to black.
- `lwd` the line width for the connection lines. Default is 1.
- `lty` the line type for the connection lines. Line types can either be specified as an integer (0=blank, 1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "blank", "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash". Default is "solid".
- `xalign` defines where the lines should be aligned to on the x-axis. Can be set either to the margins of the bars ("mar" which is the default) or to "mid". The latter will lead the connecting lines to the middle of the bars.

ConoverTest

**Conover’s Test of Multiple Comparisons**

Description

Perform Conover’s test of multiple comparisons using rank sums as post hoc test following a significant `kruskal.test`.

Usage

```r
ConoverTest(x, ...)
```

## Default S3 method:

```r
ConoverTest(x, g,
    method = c("holm", "hochberg", "hommel", "bonferroni", "BH",
        "BY", "fdr", "none"),
    alternative = c("two.sided", "less", "greater"),
    out.list = TRUE, ...)
```

## S3 method for class 'formula'

```r
ConoverTest(formula, data = NULL, ...)
```
ConoverTest(formula, data, subset, na.action, ...)

Arguments

x  
a numeric vector of data values, or a list of numeric data vectors.
g  
a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
method  
the method for adjusting p-values for multiple comparisons. The function is calling p.adjust and this parameter is directly passed through.
alternative  
a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
out.list  
logical, indicating if the results should be printed in list mode or as a square matrix. Default is list (TRUE).
formula  
a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data  
an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset  
an optional vector specifying a subset of observations to be used.
na.action  
a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

Details

ConoverTest performs the post hoc pairwise multiple comparisons procedure appropriate to follow the rejection of a Kruskal-Wallis test. Conover’s test is more powerful than Dunn’s post hoc multiple comparisons test (DunnTest). The interpretation of stochastic dominance requires an assumption that the CDF of one group does not cross the CDF of the other. ConoverTest makes \( m = k(k-1)/2 \) multiple pairwise comparisons based on the Conover-Iman t-test-statistic for the rank-sum differences:

\[
|\bar{R}_i - \bar{R}_j| > t_{1-\alpha/2,n-k} \cdot \sqrt{s^2 \cdot \left[ \frac{n - 1 - \hat{H}^*}{n - k} \right] \cdot \left[ \frac{1}{n_i} + \frac{1}{n_j} \right]}
\]

with the (tie corrected) statistic of the Kruskal Wallis test

\[
\hat{H}^* = \frac{12}{n(n+1)} \cdot \sum_{i=1}^{k} \frac{n_i^2}{n_i} - 3 \cdot (n + 1)
\]

and the \( s^2 \) being

\[
s^2 = \frac{1}{n - 1} \cdot \left[ \sum R_i^2 - n \cdot \frac{(n + 1)^2}{4} \right]
\]
If \( x \) is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, \( g \) is ignored, and one can simply use \texttt{ConoverTest(x)} to perform the test. If the samples are not yet contained in a list, use \texttt{ConoverTest(list(x,...))}.

Otherwise, \( x \) must be a numeric data vector, and \( g \) must be a vector or factor object of the same length as \( x \) giving the group for the corresponding elements of \( x \).

**Value**

A list with class "DunnTest" containing the following components:

- \texttt{res} an array containing the mean rank differences and the according p-values

**Unit Conversion and Metric Prefixes**

**Description**

Converts a numerical vector from one measurement system to another. Metric prefixes (as unit prefixes that precede a basic unit of measure to indicate a multiple or fraction of the unit) are respected.

**Usage**

- `CmToPts(x)`
- `PtsToCm(x)`
- `ConvUnit(x, from, to)`

**Arguments**

- `x` - the numeric to be converted.
- `from` - a character defining the original unit.
- `to` - a character defining the target unit.

**Details**

The two functions `CmToPts()` and `PtsToCm()` convert centimeters to points and vice versa. 1 cm corresponds to 28.35 points.

The units as defined by the International System of Units (SI) (m, g, s, A, K, mol, cd, Hz, rad, sr, N, Pa, J, W, C, V, F, Ohm, S, Wb, T, H, lm, lx, Bq, Gy, Sv, kat, l) can be used to convert between different prefixes. The following non SI-units can be chosen for conversion between different systems. NA will be returned if a conversion can’t be found.

The function is using the conversion factors stored in the dataset `d.units`.

# conversion between non-SI units
ConvUnit(1000, "yd", "mi")
# ... must be the same as
ConvUnit(ConvUnit(1000, "yd", "m"), "m", "mi")

Description

Cov and Cor compute the covariance or correlation of x and y if these are vectors. If x and y are matrices then the covariances (or correlations) between the columns of x and the columns of y are computed.

Usage

Cov(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

Cor(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

Arguments

x a numeric vector, matrix or data frame.
y

NULL (default) or a vector, matrix or data frame with compatible dimensions to
x. The default is equivalent to y = x (but more efficient).

use

an optional character string giving a method for computing covariances in the
presence of missing values. This must be (an abbreviation of) one of the strings
"everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".

method

a character string indicating which correlation coefficient (or covariance) is to
be computed. One of "pearson" (default), "kendall", or "spearman": can be
abbreviated.

Details

For Cov and Cor one must either give a matrix or data frame for x or give both x and y.

The inputs must be numeric (as determined by is.numeric: logical values are also allowed for
historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs
but xtfrm can be used to find a suitable prior transformation to numbers.

If use is "everything", NAs will propagate conceptually, i.e., a resulting value will be NA whenever
one of its contributing observations is NA.

If use is "all.obs", then the presence of missing observations will produce an error. If use is
"complete.obs" then missing values are handled by casewise deletion (and if there are no complete
cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives NA. Finally, if use
has the value "pairwise.complete.obs" then the correlation or covariance between each pair of
variables is computed using all complete pairs of observations on those variables. This can result in
covariance or correlation matrices which are not positive semi-definite, as well as NA entries if there
are no complete pairs for that pair of variables. For Cov and Var, "pairwise.complete.obs" only
works with the "pearson" method. Note that (the equivalent of) Var(double(0),use = *) gives
NA for use = "everything" and "na.or.complete", and gives an error in the other cases.

The denominator n − 1 is used which gives an unbiased estimator of the (co)variance for i.i.d.
observations. These functions return NA when there is only one observation (whereas S-PLUS has
been returning NaN), and fail if x has length zero.

For Cor(), if method is "kendall" or "spearman", Kendall’s τ or Spearman’s ρ statistic is used to
estimate a rank-based measure of association. These are more robust and have been recommended
if the data do not necessarily come from a bivariate normal distribution.

For Cov(), a non-Pearson method is unusual but available for the sake of completeness. Note that
"spearman" basically computes Cor(R(x),R(y)) (or Cov(.,.)) where R(u) := rank(u,na.last
= "keep"). In the case of missing values, the ranks are calculated depending on the value of use,
either based on complete observations, or based on pairwise completeness with reranking for each
pair.

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically
most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by
using sweep(.,FUN = "/") twice.

Value

For r <- Cor(*,use = "all.obs"), it is now guaranteed that all(abs(r) <= 1).
Note
Some people have noted that the code for Kendall’s tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function cor.fk in package pcaPP.

**CorPart**

*Find the Correlations for a Set x of Variables With Set y Removed*

**Description**

A straightforward application of matrix algebra to remove the effect of the variables in the y set from the x set. Input may be either a data matrix or a correlation matrix. Variables in x and y are specified by location.

**Usage**

```r
CorPart(m, x, y)
```

**Arguments**

- `m` a data or correlation matrix.
- `x` the variable numbers associated with the X set.
- `y` the variable numbers associated with the Y set.

**Details**

It is sometimes convenient to partial the effect of a number of variables (e.g., sex, age, education) out of the correlations of another set of variables. This could be done laboriously by finding the residuals of various multiple correlations, and then correlating these residuals. The matrix algebra alternative is to do it directly.

**Value**

The matrix of partial correlations.

abstr <- c(9,11,13,14,9,10,11,10,8,13,7,9,13,14)
coord <- c(8,12,14,13,14,8,9,12,8,9,14,7,10,12,12)
age <- c(6,8,9,9,10,7,8,9,8,7,10,6,10,10,9)

# calculate the correlation of abstr and coord, after without the effect of the age
CorPart(cbind(abstr, coord, age), 1:2, 3)

# by correlation matrix m
m <- cor(cbind(abstr, coord, age))
CorPart(m, 1:2, 3)

# ... which would be the same as:
lm1 <- lm(abstr ~ age)
lm2 <- lm(coord ~ age)
cor(resid(lm1), resid(lm2))

CorPolychor

Polychoric Correlation

Description

Computes the polychoric correlation (and its standard error) between two ordinal variables or from their contingency table, under the assumption that the ordinal variables dissect continuous latent variables that are bivariate normal. Either the maximum-likelihood estimator or a (possibly much) quicker "two-step" approximation is available. For the ML estimator, the estimates of the thresholds and the covariance matrix of the estimates are also available.

Usage

CorPolychor(x, y, ML = FALSE, control = list(), std.err = FALSE, maxcor=.9999)

## S3 method for class 'CorPolychor'
print(x, digits = max(3, getOption("digits") - 3), ...)
Arguments

x  a contingency table of counts or an ordered categorical variable; the latter can be numeric, logical, a factor, or an ordered factor, but if a factor, its levels should be in proper order.
y  if x is a variable, a second ordered categorical variable.
ML if TRUE, compute the maximum-likelihood estimate; if FALSE, the default, compute a quicker “two-step” approximation.
control optional arguments to be passed to the optim function.
std.err if TRUE, return the estimated variance of the correlation (for the two-step estimator) or the estimated covariance matrix (for the ML estimator) of the correlation and thresholds; the default is FALSE.
maxcor maximum absolute correlation (to insure numerical stability).
digits integer, determining the number of digits used to format the printed result
... not used

Value

If std.err is TRUE, returns an object of class "polycor" with the following components:
type set to "polychoric".
rho the CorPolychoric correlation.
var the estimated variance of the correlation, or, for the ML estimate, the estimated covariance matrix of the correlation and thresholds.
n the number of observations on which the correlation is based.
chisq chi-square test for bivariate normality.
df degrees of freedom for the test of bivariate normality.
ML TRUE for the ML estimate, FALSE for the two-step estimate.

Otherwise, returns the polychoric correlation.

Note

This is a verbatim copy from polchor function in the package polycor.

CountCompCases

Count Complete Cases

See Also
hetcor, polyserial, print.CorPolychor, optim

Examples

set.seed(12345)
z <- RndPairs(1000, 0.6)
x <- z[,1]
y <- z[,2]
cor(x, y) # sample correlation
x <- cut(x, c(-Inf, .75, Inf))
y <- cut(y, c(-Inf, -1, .5, 1.5, Inf))
CorPolychor(x, y) # 2-step estimate
CorPolychor(x, y, ML=TRUE, std.err=TRUE) # ML estimate

Description

Return for each variable of a data frame the number of missing values and the complete cases to be expected if this variable would be omitted.

Usage

CountCompCases(x)

## S3 method for class 'CountCompCases'
print(x, digits=1, ...)

Arguments

x a data.frame containing the data.
digits the number of digits to be used when printing the results.
... the dots are not further used.

Value

A list with three elements. The first gives the number of rows, the second the number of complete cases for the whole data frame. The third element tab contains the data for the single variables.

Author(s)

Andri Signorell <andri@signorell.net>
CountWorkDays

**Description**

Returns the number of work days between two dates taking into account the provided holiday dates.

**Usage**

CountWorkDays(from, to, holiday = NULL, nonworkdays = c("Sat", "Sun"))

**Arguments**

- **from**: the initial dates
- **to**: the final dates
- **holiday**: a vector with dates to be excluded.
- **nonworkdays**: a character vector containing the abbreviations of the weekdays (as in `day.abb`) to be considered non work days. Default is c("Sat", "Sun").

**Details**

The function is vectorised so that multiple initial and final dates can be supplied. The dates are recycled, if their number are different.

**Value**

an integer vector

**Author(s)**

Andri Signorell <andri@signorell.net>

`weekdays`, Date Functions
Examples

```r
from <- as.Date("2019-01-01") + rep(0, 10)
to <- as.Date("2020-01-15") + seq(0, 9)

CountWorkDays(from, to)

x <- seq(from[1], from[1]+11, "days")
data.frame(
  date = x,
  day = format(x, fmt="ddd")
)

CountWorkDays(from = min(x), to = max(x), holiday = c("2019-01-06", "2019-01-07"))
```

CourseData

**Get HWZ Datasets**

**Description**

Wrapper for didactical datasets used in statistic courses.

**Usage**

```r
CourseData(name, url = NULL, header = TRUE, sep = ";", ...)```

**Arguments**

- **name**: the name of the file, usually without extension.
- **url**: a url where the data reside, should have the form "http://www.mysite.net/data/". Defaults to the data folder on my site.
- **header**: a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the number of columns.
- **sep**: the field separator character. Values on each line of the file are separated by this character. Default is - unlike in `read.table` - ";" instead of 'white space'.
- ... the dots are sent to `read.table`.

**Value**

A `data.frame` containing a representation of the data in the file.

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

CramerVonMisesTest

Cramer-von Mises Test for Normality

Description

Performs the Cramer-von Mises test for the composite hypothesis of normality, see e.g. Thode (2002, Sec. 5.1.3).

Usage

```r
CramerVonMisesTest(x)
```

Arguments

- `x` a numeric vector of data values, the number of which must be greater than 7. Missing values are allowed.

Details

The Cramer-von Mises test is an EDF omnibus test for the composite hypothesis of normality. The test statistic is

\[
W = \frac{1}{12n} + \sum_{i=1}^{n} \left( p(i) - \frac{2i - 1}{2n} \right),
\]

where \( p(i) = \Phi([x(i) - \overline{x}]/s) \). Here, \( \Phi \) is the cumulative distribution function of the standard normal distribution, and \( \overline{x} \) and \( s \) are mean and standard deviation of the data values. The p-value is computed from the modified statistic \( Z = W(1.0 + 0.5/n) \) according to Table 4.9 in Stephens (1986).

Value

A list of class htest, containing the following components:

- `statistic` the value of the Cramer-von Mises statistic.
- `p.value` the p-value for the test.
- `method` the character string “Cramer-von Mises normality test”.
- `data.name` a character string giving the name(s) of the data.

Author(s)

Juergen Gross <gross@statistik.uni-dortmund.de>
Cronbach's Coefficient Alpha

Description

Cronbach’s alpha is a measure of internal consistency and often used for validating psychometric tests. It determines the internal consistency or average correlation of items in a survey instrument to gauge its reliability. This reduces to Kuder-Richardson formula 20 (KR-20) when the columns of the data matrix are dichotomous.

Usage

CronbachAlpha(x, conf.level = NA, cond = FALSE, na.rm = FALSE)

Arguments

- **x**: \( n \times m \) matrix or dataframe with item responses, \( k \) subjects (in rows) \( m \) items (in columns).
- **conf.level**: confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
- **cond**: logical. If set to TRUE, alpha is additionally calculated for the dataset with each item left out.
- **na.rm**: logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.

Examples

```r
CramerVonMisesTest(rnorm(100, mean = 5, sd = 3))
CramerVonMisesTest(runif(100, min = 2, max = 4))
```
Value

Either a numeric value or
a named vector of 3 columns if confidence levels are required (estimate, lower and upper ci) or

a list containing the following components, if the argument cond is set to TRUE:

- unconditional Cronbach’s Alpha, either the single value only or with confidence intervals
- condCronbachAlpha

  The alpha that would be realized if the item were excluded

Author(s)

Andri Signorell <andri@signorell.net>, based on code of Harold C. Doran

  item3=sample(c(0,1), 20, replace=TRUE),
  item4=sample(c(0,1), 20, replace=TRUE),
  item5=sample(c(0,1), 20, replace=TRUE)
)
CronbachAlpha(tmp[,1:4], cond=FALSE, conf.level=0.95)
CronbachAlpha(tmp[,1:4], cond=TRUE, conf.level=0.95)
CronbachAlpha(tmp[,1:4], cond=FALSE)
CronbachAlpha(tmp[,1:2], cond=TRUE, conf.level=0.95)
```

## Not run:
# Calculate bootstrap confidence intervals for CronbachAlpha
library(boot)
cronbach.boot <- function(data,x) {CronbachAlpha(data[x,][3])}
res <- boot(datafile, cronbach.boot, 1000)
quantile(res$t, c(0.025,0.975)) # two-sided bootstrapped confidence interval of Cronbach's alpha
boot.ci(res, type="bca") # adjusted bootstrap percentile (BCa) confidence interval (better)

## End(Not run)
Cross

Vector Cross Product

Description

Vector or cross product

Usage

Cross(x, y)

Arguments

x numeric vector or matrix

y numeric vector or matrix

Details

Computes the cross (or: vector) product of vectors in 3 dimensions. In case of matrices it takes the first dimension of length 3 and computes the cross product between corresponding columns or rows.

The more general cross product of n-1 vectors in n-dimensional space is realized as CrossN.

Value

3-dim. vector if x and < are vectors, a matrix of 3-dim. vectors if x and y are matrices themselves.

Author(s)

Hans W. Borchers <hwborchers@googlemail.com>

See Also

Dot, CrossN

Examples

Cross(c(1, 2, 3), c(4, 5, 6)) # -3 6 -3

# Triple product can be calculated as:
va <- c(1, 2, 3)
vb <- c(4, 3, 0)
vC <- c(5, 1, 1)

Dot(va, Cross(vb, vc))
CrossN  

*n-dimensional Vector Cross Product*

**Description**

Vector cross product of \( n-1 \) vectors in \( n \)-dimensional space

**Usage**

```r
CrossN(A)
```

**Arguments**

- \( A \)  
  matrix of size \( (n-1) \times n \) where \( n \geq 2 \).

**Details**

The rows of the matrix \( A \) are taken as \( (n-1) \) vectors in \( n \)-dimensional space. The cross product generates a vector in this space that is orthogonal to all these rows in \( A \) and its length is the volume of the geometric hypercube spanned by the vectors.

**Value**

a vector of length \( n \)

**Note**

The 'scalar triple product' in \( \mathbb{R}^3 \) can be defined as

```r
spatproduct <- function(a, b, c) Dot(a, CrossN(b, c))
```

It represents the volume of the parallelepiped spanned by the three vectors.

**Author(s)**

Hans W. Borchers <hwborchers@googlemail.com>

**See Also**

Cross, Dot

**Examples**

```r
A <- matrix(c(1,0,0, 0,1,0), nrow=2, ncol=3, byrow=TRUE)
CrossN(A)  #=> 0 0 1
x <- c(1.0, 0.0, 0.0)
y <- c(1.0, 0.5, 0.0)
z <- c(0.0, 0.0, 1.0)
identical(Dot(x, CrossN(rbind(y, z))), det(rbind(x, y, z)))
```
Description

Calculate the C statistic, a measure of goodness of fit for binary outcomes in a logistic regression or any other classification model. The C statistic is equivalent to the area under the ROC-curve (Receiver Operating Characteristic).

Usage

Cstat(x, ...)

## S3 method for class 'glm'
Cstat(x, ...)

## Default S3 method:
Cstat(x, resp, ...)

Arguments

x the linear model
resp the response variable
... further arguments to be passed to other functions.

Details

Values for this measure range from 0.5 to 1.0, with higher values indicating better predictive models. A value of 0.5 indicates that the model is no better than chance at making a prediction of membership in a group and a value of 1.0 indicates that the model perfectly identifies those within a group and those not. Models are typically considered reasonable when the C-statistic is higher than 0.7 and strong when C exceeds 0.8.

Confidence intervals for this measure can be calculated by bootstrap.

Value

numeric value

Author(s)

Andri Signorell <andri@signorell.net>

References

### Description
Create a factor variable using the quantiles of a continuous variable.

### Usage

```r
CutQ(x, breaks = quantile(x, seq(0, 1, by = 0.25), na.rm = TRUE),
    labels = NULL, na.rm = FALSE, ...)
```

### Arguments
- `x`  
  continous variable.
- `breaks`  
  the breaks for creating groups. By default the quartiles will be used, say `quantile(seq(0, 1, by = 0.25), na.rm = TRUE)`. See `quantile` for details.
- `labels`  
  labels for the levels of the resulting category. By default, labels are defined as Q1, Q2 to the length of breaks - 1. The parameter ist passed to `cut`, so if `labels` are set to FALSE, simple integer codes are returned instead of a factor.
- `na.rm`  
  Boolean indicating whether missing values should be removed when computing quantiles. Defaults to TRUE.
- `...`  
  Optional arguments passed to `cut`.

### Details
This function uses `quantile` to obtain the specified quantiles of `x`, then calls `cut` to create a factor variable using the intervals specified by these quantiles.

It properly handles cases where more than one quantile obtains the same value, as in the second example below. Note that in this case, there will be fewer generated factor levels than the specified number of quantile intervals.

### Value
Factor variable with one level for each quantile interval given by q.

d.countries

ISO 3166-1 Country Codes

Description

Country codes published by the International Organization for Standardization (ISO) define codes for the names of countries, dependent territories, and special areas of geographical interest.

Usage

data("d.countries")

Format

A data frame with 249 observations on the following 4 variables.

name  a character vector, the name of the country.
a2  a character vector, two-letter country codes (aka alpha-2) which are the most widely used of the three, and used most prominently for the Internet’s country code top-level domains (with a few exceptions).
a3 a character vector, three-letter country codes (aka alpha-3) which allow a better visual association between the codes and the country names than the alpha-2 codes.

code a numeric vector, three-digit country codes which are identical to those developed and maintained by the United Nations Statistics Division, with the advantage of script (writing system) independence, and hence useful for people or systems using non-Latin scripts.

region the region of the country. One of "East Asia & Pacific" (35), "Europe & Central Asia" (52), "Latin America & Caribbean" (41), "Middle East & North Africa" (20), "North America" (3), "South Asia" (8), "Sub-Saharan Africa" (47)

pop2012 the population in 2012
gcp2012 the gross national income (per capita) in dollars per country in 2012.

d.periodic

Periodic Table of Elements

Description

This data.frame contains the most important properties of the periodic table of the elements.

Usage

data(d.periodic)

Format

A data frame with 110 observations on the following 24 variables.

- symbol: symbol of an element.
- nr: atomic number of an atomic symbol.
- name: name of an element.
- group: group of an element. Possible results are: Alkali Earth, Alkali Met., Halogen, Metal, Noble Gas, Non-Metal, Rare Earth and Trans. Met.
- weight: atomic weight of an element. The values are based upon carbon-12. () indicates the most stable or best known isotope.
- meltpt: melting point of an element in [K].
- boilpt: boiling point of an element in Kelvin [K].
- dens: density of an element in [g/cm³] at 300K and 1 atm.
- elconf: electron configuration of an element.
- oxstat: oxidation states of an element. The most stable is indicated by a "!".
- struct: crystal structure of an element. Possible results are: Cubic, Cubic body centered, Cubic face centered, Hexagonal, Monoclinic, Orthorhombic, Rhombohedral, Tetragonal
- covrad: covalent radius of an element in Angstroem [Å].
- arad: atomic radius of an element in Angstroem.
- avol: atomic volume of an element in [cm³/mol].
spheat  specific heat of an element in [J/(g K)].
eneg  electronegativity (Pauling’s) of an element.
 fusheat heat of fusion of an element in [kJ/mol].
vapheat heat of vaporization of an element in [kJ/mol].
elcond electrical conductivity of an element in [1/(Ohm cm)].
thermcond thermal conductivity of an element in [W/(cm K)].
ionpot1 first ionization potential of an element in [V].
ionpot2 second ionization potential of an element in [V].
ionpot3 third ionization potential of an element in [V].
discyear year of discovery of the element

D. pizza

Data pizza

Description

An artificial dataset inspired by a similar dataset pizza.sav in Arbeitsbuch zur deskriptiven und induktiven Statistik by Toutenburg et.al.
The dataset contains data of a pizza delivery service in London, delivering pizzas to three areas. Every record defines one order/delivery and the according properties. A pizza is supposed to taste good, if its temperature is high enough, say 45 Celsius. So it might be interesting for the pizza delivery service to minimize the delivery time.
The dataset is designed to be as evil as possible. As far as the description is concerned, it should pose the same difficulties that we have to deal with in everyday life. It contains the most used datatypes as numerics, factors, ordered factors, integers, logicals and a date. NAs are scattered everywhere partly systematically, partly randomly (except in the index).

Usage

data(d.pizza)

Format

A data frame with 1209 observations on the following 17 variables.

index  a numeric vector, indexing the records (no missings here).
date  Date, the delivery date
week  integer, the weeknumber
weekday integer, the weekday
area  factor, the three London districts: Brent, Camden, Westminster
count integer, the number of pizzas delivered
rabate logical, TRUE if a rabate has been given
price numeric, the total price of delivered pizza(s)
operator a factor with levels Allanah Maria Rhonda
driver a factor with levels Carpenter Carter Taylor Butcher Hunter Miller Farmer
delivery_min numeric, the delivery time in minutes (decimal)
temperature numeric, the temperature of the pizza in degrees Celsius when delivered to the customer
wine_ordered integer, 1 if wine was ordered, 0 if not
wine_delivered integer, 1 if wine was delivered, 0 if not
wrongpizza logical, TRUE if a wrong pizza was delivered
quality ordered factor with levels low < medium < high, defining the quality of the pizza when delivered

Details
The dataset contains NAs randomly scattered.

**d.whisky**

*Classification of Scotch Single Malts*

**Description**

86 malt whiskies are scored between 0-4 for 12 different taste categories including sweetness, smoky, nutty etc. Additionally, coordinates of distilleries allow us to obtain pairwise distance information. Using a combination of these variables it is possible to look for correlations between particular attributes of taste and physical location, for example does a shared local resource have a significant effect on nearby whiskies.

By using correlation analysis it may be possible to provide whisky recommendations based upon an individual’s particular preferences. By computing the Pearson correlation coefficient and specifying a threshold value between 0 and 1, we can establish an adjacency matrix where each node is a malt whisky and an edge represents a level of similarity above the threshold.
Usage

`data("d.whisky")`

Format

A data frame with 86 observations on the following 16 variables.

distillery a character Aberfeldy, Aberlour, AnCnoc, Ardbeg, ...
brand a grouping factor to separate the better known distilleries (A) from the lesser known ones (B).
region a factor with levels campbeltown, highland, islands, islay, lowland, speyside.
body a numeric vector
sweetness a numeric vector
smoky a numeric vector
medicinal a numeric vector
tobacco a numeric vector
honey a numeric vector
spicy a numeric vector
winey a numeric vector
nutty a numeric vector
malty a numeric vector
fruity a numeric vector
floral a numeric vector
postcode a character AB30 1YE, AB35 5TB, ...
latitude a numeric vector, coordinate pairs of distilleries.
longitude a numeric vector, coordinate pairs of distilleries.

Datasets for Simulation

Datasets for Probabilistic Simulation

Description

For performing elementary probability calculations in introductory statistic courses, we might want to simulate random games. The dataset `roulette` contains the standard sample space for one spin on a roulette wheel. `cards` contains the standard set of 52 playing cards in four colours (without Jokers). `tarot` does the same with a classic tarot deck.

Usage

cards
tarot
roulette

Value

cards is a data.frame with three columns named card, rank and suit
tarot is a data.frame with four columns named card, rank, suit and desc
roulette is a data.frame with seven columns named num and col, parity, highlow, dozens, column, pocketrange

See Also

Sample, sample()

Examples

head(cards)
head(tarot)
head(roulette)

# drawing 5 cards
sample(cards$card, 5)
# drawing 5 cards with jokers
sample(c(cards$card, rep("Joker", 3)), 5)

# spin the wheel by using the DescTools::Sample() for sampling
# rows from a data frame
Sample(roulette, size=1)

# simulate the evening in Las Vegas with 10 games
Sample(roulette, 10, replace=TRUE)

---

## Date Functions

### Basic Date Functions

**Description**

Some more date functions for making daily life a bit easier. The first ones extract a specific part of a given date, others check some conditions.

**Usage**

```r
Year(x)
Quarter(x)
Month(x, fmt = c("m", "mm", "mmm"), lang = DescToolsOptions("lang"),
stringsAsFactors = TRUE)
Week(x, method = c("iso", "us"))
Day(x)
Weekday(x, fmt = c("d", "dd", "ddd"), lang = DescToolsOptions("lang"),
stringsAsFactors = TRUE)
YearDay(x)
YearMonth(x)

Day(x) <- value

IsWeekend(x)
IsLeapYear(x)

Hour(x)
Minute(x)
Second(x)
Timezone(x)

Now()
Today()

DiffDays360(start_d, end_d, method = c("eu", "us"))
LastDayOfMonth(x)
```
**Date Functions**

**Arguments**

- **x**
  - the date to be evaluated.
- **fmt**
  - format string, defines how the month or the weekday are to be formatted. Defaults to "m", resp. "d". Is ignored for other functions.
- **value**
  - new value
- **lang**
  - optional value setting the language for the months and daynames. Can be either "local" for current locale or "engl" for english. If left to NULL, the option "lang" will be searched for and if not found "local" will be taken as default.
- **stringsAsFactors**
  - logical. Defines if the result should be coerced to a factor, using the local definitions as levels. The result would be an ordered factor. Default is TRUE.
- **start_d, end_d**
  - the start, resp. end date for DiffDays360.
- **method**
  - one out of "eu", "us", setting either European or US-Method calculation mode. Default is "eu".

**Details**

These functions are mainly convenience wrappers for the painful format() and its strange codes...

Based on the requested time component, the output is as follows:

- **Year** returns the year of the input date in yyyy format.
- **Quarter** returns the quarter of the year (1 to 4) for the input date.
- **Month** returns the month of the year (1 to 12) for the input date.
- **Week** returns the week of the year for the input date (0 to 53), as defined in ISO8601.
- **Weekday** returns the week day of the input date. (1 - Monday, 2 - Tuesday, ... 7 - Sunday). (Names and abbreviations are either english or in the current locale!)
- **YearDay** returns the day of the year numbering (1 to 366).
- **Day** returns the day of the month (1 to 31).
- **YearMonth** returns the yearmonth representation (yyyymm) of a date as long integer.
- **Hour, Minute, Second, Timezone** return the hour, minute, second or timezone from a POSIXlt object.
- **Today, Now** return the current date, resp. the current date and time.

- **IsWeekend** returns TRUE, if the date x falls on a weekend.
- **IsLeapYear** returns TRUE, if the year of the date x is a leap year.

The day can not only be extracted, but as well be defined. See examples.

- **DiffDays360** calculates the difference between 2 dates using the 360-days convention.
- **LastDayOfMonth** returns the last day of the month of the given date(s).

The language in Weekday and Moth can be set with an option as well. The functions will check for an existing option named "lang" and take this value if it exists. So simply set option(lang="engl") if the results should always be reported in english.

**Value**

a vector of the same dimension as x, consisting of either numeric values or characters depending on the function used.

IsWeekend(x)

IsLeapYear(x)

# let's generate a time sequence by weeks
Month(seq(from=as.Date(Sys.Date()), to=Sys.Date()+150, by="weeks"), fmt="mm")

LastDayOfMonth(as.Date(c("2014-10-12","2013-01-31","2011-12-05")))
```

day.name

---

Build-in Constants Extension

Description

There’s a small number of built-in constants in R. We have `month.name` and `month.abb` but nothing similar for weekdays. Here it is.
DegToRad

Usage

day.name
day.abb

Details

The following constants are available in DescTools:

• day.name: the English names for the day of the week (Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Sunday);
• day.abb: the three-letter abbreviations for the English day names (Mon, Tue, Wed, Thu, Fri, Sat, Sun);

See Also

month.name, month.abb

---

DegToRad Convert Degrees to Radians and Vice Versa

Description

Convert degrees to radians (and back again).

Usage

DegToRad(deg)
RadToDeg(rad)

Arguments

deg a vector of angles in degrees.
rad a vector of angles in radians.

Value

DegToRad returns a vector of the same length as deg with the angles in radians. RadToDeg returns a vector of the same length as rad with the angles in degrees.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

DegToRad(c(90,180,270))
RadToDeg(c(0.5,1,2) * pi)
**DenseRank**

**Dense Ranks and Percent Ranks**

**Description**

DenseRank() computes the rank of a vector x and returns the rank as a number. The ranks are consecutive integers beginning with 1. No ranks are skipped if there are ranks with multiple items. So the largest rank value is the number of unique values of x. Unlike rank gives the ranking within the vector x too, but ties are assigned the same rank, with the next ranking(s) skipped.

PercentRank() takes a vector x and returns the percentile that elements of x correspond to.

**Usage**

DenseRank(x, na.last = TRUE)

PercentRank(x)

**Arguments**

- **x**
  a numeric, complex, character or logical vector.

- **na.last**
  for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.

**Value**

A numeric vector of the same length as x with names copied from x (unless na.last = NA, when missing values are removed). The vector is of integer type unless x is a long vector.

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

`rank`, `factor`, `order`, `sort`

**Examples**

(r1 <- rank(x1 <- c(3, 1, 4, 15, 92)))

x2 <- c(3, 1, 4, 1, 5, 9, 2, 6, 5, 3, 5)
names(x2) <- letters[1:11]
(r2 <- rank(x2))  # ties are averaged
(r2 <- DenseRank(x2))  # ranks are enumerated

PercentRank(x2)
Depreciation

Several Methods of Depreciation of an Asset

Description

Return the depreciation of an asset for a specified period using different methods. SLN returns the straight-line depreciation DB uses the fixed-declining balance method and SYD returns the sum-of-years’ digits depreciation.

Usage

SLN(cost, salvage, life)
DB(cost, salvage, life, period = 1:life)
SYD(cost, salvage, life, period = 1:life)

Arguments

cost initial cost of the asset.
salvage value at the end of the depreciation (sometimes called the salvage value of the asset).
life number of periods over which the asset is depreciated (sometimes called the useful life of the asset).
period period for which you want to calculate the depreciation. Period must use the same units as life.

Value

val

Author(s)

Andri Signorell <andri@signorell.net>

See Also

NPV()

Examples

# depreciation allowance for each year
SLN(cost = 50000, salvage = 10000, life = 5)
DB(cost = 50000, salvage = 10000, life = 5)

50000 - c(0, cumsum(SYD(cost = 50000, salvage = 10000, life = 5)))
Description

Produce summaries of various types of variables. Calculate descriptive statistics for x and use Word as reporting tool for the numeric results and for descriptive plots. The appropriate statistics are chosen depending on the class of x. The general intention is to simplify the description process for lazy tyers and return a quick, but rich summary.

A 2-dimensional table will be described with it's relative frequencies, a short summary containing the total cases, the dimensions of the table, chi-square tests and some association measures as phi-coefficient, contingency coefficient and Cramer's V.
Tables with higher dimensions will simply be printed as flat table, with marginal sums for the first and for the last dimension.

Usage

Desc(x, ..., main = NULL, plotit = NULL, wrd = NULL)

## Default S3 method:
Desc(x, main = NULL, maxrows = NULL, ord = NULL,
    conf.level = 0.95, verbose = 2, rfrq = "111", margins = c(1,2),
    dprobs = NULL, mprobs = NULL, plotit = NULL, sep = NULL, digits = NULL, ...)

## S3 method for class 'data.frame'
Desc(x, main = NULL, plotit = NULL, enum = TRUE, sep = NULL, ...)

## S3 method for class 'list'
Desc(x, main = NULL, plotit = NULL, enum = TRUE, sep = NULL, ...)

## S3 method for class 'numeric'
Desc(x, main = NULL, maxrows = NULL, plotit = NULL,
    sep = NULL, digits = NULL, ...)

## S3 method for class 'integer'
Desc(x, main = NULL, maxrows = NULL, plotit = NULL,
    sep = NULL, digits = NULL, ...)

## S3 method for class 'factor'
Desc(x, main = NULL, maxrows = NULL, ord = NULL, plotit = NULL,
    sep = NULL, digits = NULL, ...)

## S3 method for class 'ordered'
Desc(x, main = NULL, maxrows = NULL, ord = NULL, plotit = NULL,
    sep = NULL, digits = NULL, ...)

## S3 method for class 'character'
Desc(x, main = NULL, maxrows = NULL, ord = NULL, plotit = NULL,
sep = NULL, digits = NULL, ...)

## S3 method for class 'logical'
Desc(x, main = NULL, ord = NULL, conf.level = 0.95, plotit = NULL,
sep = NULL, digits = NULL, ...)

## S3 method for class 'Date'
Desc(x, main = NULL, dprobs = NULL, mprobs = NULL, plotit = NULL,
sep = NULL, digits = NULL, ...)

## S3 method for class 'table'
Desc(x, main = NULL, conf.level = 0.95, verbose = 2,
rfrq = "111", margins = c(1,2), plotit = NULL, sep = NULL, digits = NULL, ...)

## S3 method for class 'formula'
Desc(formula, data = parent.frame(), subset, main = NULL,
plotit = NULL, digits = NULL, ...)

## S3 method for class 'Desc'
print(x, digits = NULL, plotit = NULL, nolabel = FALSE,
sep = NULL, ...)

## S3 method for class 'Desc'
plot(x, main = NULL, ...)

**Arguments**

- **x**: the object to be described. This can be a data.frame, a list, a table or a vector of the classes: numeric, integer, factor, ordered factor, logical.
- **main**: a character vector, containing the main title(s). If this is left to NULL, the title will be composed as: variablename (class(es)), resp. number - variablename (class(es)) if the enum option is set to TRUE. Use NA if no caption should be printed at all.
- **wrd**: the pointer to a running MS Word instance, as created by GetNewWrd() (for a new one) or by GetCurrWrd() for an existing one. All output will then be redirected there. Default is NULL, which will report all results to the console.
- **digits**: integer. With how many digits should the relative frequencies be formatted? Default can be set by DescToolsOptions(digits=x).
- **maxrows**: numeric; defines the maximum number of rows in a frequency table to be reported. For factors with many levels it is often not interesting to see all of them. Default is set to 12 most frequent ones (resp. the first ones if ord is set to "levels" or "names").

For a numeric argument x maxrows is the minimum number of unique values needed for a numeric variable to be treated as continuous. If left to its default
NULL, x will be regarded as continuous if it has more than 12 single values. In this case the list of extreme values will be displayed and the frequency table else. If maxrows is < 1 it will be interpreted as percentage. In this case just as many rows, as the maxrows% most frequent levels will be shown. Say, if maxrows is set to 0.8, then the number of rows is fixed so, that the highest cumulative relative frequency is the first one going beyond 0.8.

Setting maxrows to Inf will unconditionally report all values and also produce a plot with type "h" instead of a histogram.

ord character out of "name" (alphabetical order), "level", "asc" (by frequencies ascending), "desc" (by frequencies descending) defining the order for a frequency table as used for factors, numerics with few unique values and logicals. Factors (and character vectors) are by default ordered by their descending frequencies, ordered factors by their natural order.

rfrq a string with 3 characters, each of them being 1 or 0, defining which percentages should be reported. The first position is interpreted as total percentages, the second as row percentages and the third as column percentages. "011" hence produces a table output with row and column percentages. If set to NULL rfrq is defined in dependency of verbose (verbose = "low" sets rfrq to "000" and else to "111", latter meaning all percentages will be reported.)

Applies only to tables and is ignored else.

margins a vector, consisting out of 1 and/or 2. Defines the margin sums to be included. Row margins are reported if margins is set to 1. Set it to 2 for column margins and c(1,2) for both.

Default is NULL (none).

Applies only to tables and is ignored else.

verbose integer out of c(2, 1, 3) defining the verbosity of the reported results. 2 (default) means medium, 1 less and 3 extensive results.

Applies only to tables and is ignored else.

conf.level confidence level of the interval. If set to NA no confidence interval will be calculated. Default is 0.95.

dprobs, mprobs a vector with the probabilities for the Chi-Square test for days, resp. months, when describing a Date variable. If this is left to NULL (default) then a uniform distribution will be used for days and a monthdays distribution in a non leap year (p = c(31/365, 28/365, 31/365, ...)) for the months.

Applies only to Dates and is ignored else.

enum logical, determining if in data.frames and lists a sequential number should be included in the main title. Default is TRUE. The reason for this option is, that if a Word report with enumerated headings is created, the numbers may be redundant or inconsistent.

plotit boolean. Should a plot be created? The plot type will be chosen according to the classes of variables (roughly following a numeric-numeric, numeric-categorical, categorical-categorical logic). Default can be defined by option plotit, if it does not exist then it's set to FALSE.

sep character. The separator for the title. By default a line of "-" for the current width of the screen (options("width")) will be used.
nolabel  logical, defining if labels (defined as attribute with the name label, as done by Label) should be plotted.

formula  a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data  an optional matrix or data frame containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset  an optional vector specifying a subset of observations to be used.

...  further arguments to be passed to or from other methods. For the internal default method these can include:

  p  a vector of probabilities of the same length of x. An error is given if any entry of p is negative. This argument will be passed on to chisq.test. Default is rep(1/length(x),length(x)).

add_ni  logical. Indicates if the group length should be displayed in the boxplot.

smooth  character, either "loess" or "smooth.spline" defining the type of smoother to be used in num ~ num plots. Default is loess for n < 500 and smooth.spline else.

Details

Desc is a generic function. It dispatches to one of the methods above depending on the class of its first argument. Typing ?Desc + TAB at the prompt should present a choice of links: the help pages for each of these Desc methods (at least if you’re using RStudio, which anyway is recommended). You don’t need to use the full name of the method although you may if you wish; i.e., Desc(x) is idiomatic R but you can bypass method dispatch by going direct if you wish: Desc.numeric(x).

This function produces a rich description of a factor, containing length, number of NAs, number of levels and detailed frequencies of all levels. The order of the frequency table can be chosen between descending/ascending frequency, labels or levels. For ordered factors the order default is "level". Character vectors are treated as unordered factors Desc.char converts x to a factor and processes x as factor.

Desc.ordered does nothing more than changing the standard order for the frequencies to it’s intrinsic order, which means order "level" instead of "desc" in the factor case.

Description interface for dates. We do here what seems reasonable for describing dates. We start with a short summary about length, number of NAs and extreme values, before we describe the frequencies of the weekdays and months, rounded up by a chi-square test.

A 2-dimensional table will be described with it’s relative frequencies, a short summary containing the total cases, the dimensions of the table, chi-square tests and some association measures as phi-coefficient, contingency coefficient and Cramer’s V.

Tables with higher dimensions will simply be printed as flat table, with marginal sums for the first and for the last dimension.

Note that NAs cannot be handled by this interface, as tables in general come in "as.is", say basically as a matrix without any further information about potentially previously cleared NAs.

Description of a dichotomous variable. This can either be a boolean vector, a factor with two levels or a numeric variable with only two unique values. The confidence levels for the relative frequencies are calculated by BinomCI, method “Wilson” on a confidence level defined by conf.level. Dichotomous variables can easily be condensed in one graphical representation. Desc for a set of
flags (=dichotomous variables) calculates the frequencies, a binomial confidence intervall and produces a kind of dotplot with error bars. Motivation for this function is, that dichotomous variable in general do not contain intense information. Therefore it makes sense to condense the description of sets of dichotomous variables.

The formula interface accepts the formula operators +, :, *, I(), 1 and evaluates any function. The left hand side and right hand side of the formula are evaluated the same way. The variable pairs are processed in dependency of their classes.

Word This function is not thought of being directly run by the enduser. It will normally be called automatically, when a pointer to a Word instance is passed to the function `Desc`. However `DescWrd` takes some more specific arguments concerning the Word output (like font or fontsize), which can make it necessary to call the function directly.

Value

A list containing the following components:

- `length` the length of the vector (n + NAs).
- `n` the valid entries (NAs are excluded)
- `NAs` number of NAs
- `unique` number of unique values.
- `0s` number of zeros
- `mean` arithmetic mean
- `MeanSE` standard error of the mean, as calculated by `MeanSE`.
- `quant` a table of quantiles, as calculated by `quantile(x, probs = c(.05,.10,.25,.5,.75,.9,.95), na.rm = TRUE)`.
- `sd` standard deviation
- `vcoeff` coefficient of variation: `mean(x) / sd(x)`
- `mad` median absolute deviation (mad)
- `IQR` interquartile range
- `skew` skewness, as calculated by `Skew`.
- `kurt` kurtosis, as calculated by `Kurt`.
- `highlow` the lowest and the highest values, reported with their frequencies in brackets, if > 1.
- `frq` a data.frame of absolute and relative frequencies given by `Freq` if maxlevels > unique values in the vector.

**DescTools Aliases**

**Some Aliases Set for Convenience**

**Description**

Some aliases are defined either for having shorter names or for following the Google naming convention.

**Usage**

`N()`

**Details**

`N()` is the same as `as.numeric()`

**Author(s)**

Andri Signorell <andri@signorell.net>

**Examples**

`head(N(d.pizza$driver))`
DescTools Palettes

Some Custom Palettes

Description

Some more custom palettes.

Usage

```r
Pal(pal, n = 100, alpha = 1)
```

```r
## S3 method for class 'palette'
plot(x, cex = 3, ...)
```

hred
horange
hyellow
hecru
hblue
hgreen

Arguments

- `pal` name or number of the palette. One of RedToBlack (1), RedBlackGreen (2), SteebleWhite (3), RedWhiteGreen (4), RedWhiteBlue0 (5), RedWhiteBlue1 (6), RedWhiteBlue2 (7), RedWhiteBlue3 (8), Helsana (9), Tibco (10), RedGreen1 (11), Spring (12), Soap (13), Maiden (14), Dark (15), Accent (16), Pastel (17), Fragile (18), Big (19), Long (20), Night (21), Dawn (22), Noon (23), Light (24)
- `n` integer, number of colors for the palette.
- `alpha` the alpha value to be added. This can be any value from 0 (fully transparent) to 1 (opaque). NA is interpreted so as to delete a potential alpha channel. Default is 0.5.
- `x` a palette to be plotted.
- `cex` extension for the color squares. Defaults to 3.
- `...` further arguments passed to the function.

Details

hred, horange, hyellow, hecru, hblue and hgreen are constants, pointing to the according color from the palette Pal("Helsana").

Value

a vector of colors
DescToolsOptions

DescToolsOptions  

DescTools Options  

Description  
Get and set a variety of options which affect the way in which DescTools functions display results.  

Usage  
DescToolsOptions(..., default = NULL, reset = FALSE)
DescToolsOptions

Arguments

any options can be defined, using name = value. However, only the ones below are used by DescTools functions.

default if the specified option is not set in the options list, this value is returned. This facilitates retrieving an option and checking whether it is set and setting it separately if not.

reset logical. If this is set to TRUE, the options will be overwritten with their default values. Other arguments will be ignored in this case. Default is FALSE.

Details

Invoking DescToolsOptions() with no arguments returns a list with the current values of the options. Note that not all options listed below are set initially. To access the value of a single option, one can simply use DescToolsOptions("plotit").

To set a new value use the same rationale as with the R options: DescToolsOptions(plotit=FALSE)

Options used by DescTools

col: a vector of colours, defined as names or as RGB-longns ("#RRGGBB"). By now three colors are used in several plots as defaults. By default they’re set to hblue, hred and horange. Change the values by defining DescToolsOptions(col=c("pink","blue","yellow")). Any color definition can be used here.

digits: the number of FIXED digits, used throughout the print functions.

fixedfont: this font will be used by default, when Desc writes to a Word document. Must be defined as a font object, say enumerating name, face and size of the font and setting the class font, e.g. structure(list(name="Courier New",size=7),class="font").

fmt: Three number format definitions are currently used in the Desc routines. The format used for integer values is named "abs", for percentages "perc" and for floating point numeric values "num". The format definitions must be of class "fmt" and may contain any argument used in the function Format.

Use Fmt to access and update formats (as they are organised in a nested list).

footnote: a character vector, containing characters to be used as footnote signs. Any character can be defined here. This is currently used by TOne.

lang: either "engl" or "local", defining the language to be used for the names of weekdays and months when using Format.

plotit: logical, defining whether the Desc-procedures should produce plots by default. This is usually a good thing, but it may clutter up your desktop, if you’re not using RStudio. Therefore it can be turned off.

stamp: text or expression to be placed in the right bottom corner of the DescTools plots. This can be useful, if some author or date information should automatically be inserted by default. Any text can be set as option, but also dynamic expressions can be used. The default would use an expression as <username>/<date>, which will use the username from the system and the current date. See defaults below.

Calling DescToolsOptions(reset=TRUE) will reset the options to these defaults:
options(DescToolsOptions = list(
  col = c(hblue = "#8296C4", hred = "#9A0941", horange = "#F08100"),
  digits = 3,
  fixedfont = structure(list(name = "Consolas", size = 7), class = "font"),
  fmt = list(abs = structure(list(digits = 0, big.mark = "/"),
              name = "abs", label = "Number format for counts", default = TRUE,
              class = "fmt"),
              per = structure(list(digits = 1, fmt = "%"),
              name = "per", label = "Percentage number format", default = TRUE,
              class = "fmt"),
              num = structure(list(digits = 3, big.mark = "/"),
              name = "num", label = "Number format for floats", default = TRUE,
              class = "fmt")
  ),
  footnote = c("", ",", ",\,
               ,\\", ",\""),
  lang = "engl",
  plotit = TRUE,
  stamp = expression(gettextf("%s/%s", Sys.getenv("USERNAME"),
                     Format(Today(), fmt = "yyyy-mm-dd")))
))

This code can as well be copied and pasted to the users' RProfile file, in order to have the options permanently available.

Value

For a given vector of strings the current value set for option x, or NULL if the option is unset.

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

# get some potentially undefined option, while taking a user default and
# overriding system defaults
DescToolsOptions("stamp", default="Condor, 2016")

# get an undefined option, should return default
DescToolsOptions("stampede", default="Condor, 2016")

# set options, while getting the old values
opt <- DescToolsOptions(plotit=789, lang="portugues")
DescToolsOptions()
# output the old values
opt

# just a single argument
DescToolsOptions(digits=2)

# reset the old values
DescToolsOptions(opt)
DescToolsOptions()

# reset factory defaults
DescToolsOptions(reset=TRUE)

## End(Not run)

DigitSum

### Description

Calculate digit sum of a number x.

### Usage

DigitSum(x)

### Arguments

x

an integer number

### Value

the digit sum

### Author(s)

Andri Signorell <andri@signorell.net> based on code by Julius benchmarked by Uwe
**DivCoef**

**Rao’s Diversity Coefficient**

**Description**

Calculates Rao’s diversity coefficient (also known as "Quadratic Entropy") within samples.

**Usage**

```r
DivCoef(df, dis, scale)
```

**Arguments**

- `df`: a data frame with elements as rows, samples as columns, and abundance, presence-absence or frequencies as entries.
- `dis`: an object of class `dist` containing distances or dissimilarities among elements. If `dis` is NULL, Gini-Simpson index is performed.
- `scale`: a logical value indicating whether or not the diversity coefficient should be scaled by its maximal value over all frequency distributions.

**Value**

Returns a data frame with samples as rows and the diversity coefficient within samples as columns.

**Note**

This function was previously published as `divc()` in the `ade4` package and has been integrated here without logical changes.

**Author(s)**

Sandrine Pavoine <pavoine@biomserv.univ-lyon1.fr>

```r
DigitSum(c(124, 45, 268))
# [1]  7  9 16
```
DivCoefMax

Maximal value of Rao’s diversity coefficient also called quadratic entropy

Description

For a given dissimilarity matrix, this function calculates the maximal value of Rao’s diversity coefficient over all frequency distribution. It uses an optimization technique based on Rosen’s projection gradient algorithm and is verified using the Kuhn-Tucker conditions.

Usage

DivCoefMax(dis, epsilon, comment)

Arguments

dis an object of class dist containing distances or dissimilarities among elements.
epsilon a tolerance threshold : a frequency is non null if it is higher than epsilon.
comment a logical value indicating whether or not comments on the optimization technique should be printed.

Value

Returns a list

value the maximal value of Rao’s diversity coefficient.
vectors a data frame containing four frequency distributions : sim is a simple distribution which is equal to $D_1^{1/2}$, pro is equal to $\frac{z}{\sum z}$, where $z$ is the nonnegative eigenvector of the matrix containing the squared dissimilarities among the elements, met is equal to $z^2$, num is a frequency vector maximizing Rao’s diversity coefficient.

```
Divisors

Calculate Divisors

Description

Calculate divisors of positive natural numbers.

Usage

Divisors(x)

Arguments

x                  integer number for which the divisors are to be returned

Details

Divisibility is a mathematical relationship between two integers. An integer is divisible by another integer if there is no remainder in the division. The number 11 has only two divisors: 1 and the number 11 itself, whereas the number 12 has many divisors: 1, 2, 3, 4, 6 and 12. In elementary number theory, the concept of divisibility is limited to natural numbers. The number of its divisors can be determined with the function length().

Value

an integer vector containing the divisors

Author(s)

Andri Signorell <andri@signorell.net>

Primes, IsPrime, GCD, LCM

Examples

Divisors(c(145, 786))
**DoBy**  
*Evaluates a Function Groupwise*

---

**Description**

Split the vector x into partitions and apply the function to each partition separately. Computation restarts for each partition.

The logic is the same as the OLAP functions in SQL, e.g. `SUM(x) OVER (PARTITION BY group)`.

**Usage**

```r
DoBy(x, ...)
```

### S3 method for class 'formula'

```r
DoBy(formula, data = parent.frame(), subset, na.action,  
      vnames = NULL, ...)
```

### Default S3 method:

```r
DoBy(x, by, FUN, vnames = NULL, collapse = FALSE, ...)
```

**Arguments**

- **x**  
  a vector that should be operated.

- **by**  
  list of one or more factors, each of same length as x. If by is not a factor, the elements are coerced to factors by `as.factor()`.

- **FUN**  
  Function to apply for each factor level combination.

- **formula**  
  a formula of the form `lhs ~ rhs` where lhs gives the data values and rhs the corresponding groups.

- **data**  
  an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from the `parent.frame()`.

- **subset**  
  an optional vector specifying a subset of observations to be used.

- **na.action**  
  a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

- **vnames**  
  name for the new variables.

- **collapse**  
  logical, determining if the results should be collapsed to groups. Default is `FALSE`.

- **...**  
  optional arguments to FUN: See the "Note" section.

**Details**

This is more or less the same as the function `ave`, with the arguments organized a bit different and offering more flexibility.
Value

a data.frame with the same number of rows as length as x containing the groupwise results of FUN and the used group factors.
The attribute response denotes the name of the response variable in case the formula interface was used.

Note

Optional arguments to FUN supplied by the ... argument are not divided into cells. It is therefore inappropriate for FUN to expect additional arguments with the same length as x.

d.frm <- data.frame(x=rep(1:4,3), v=sample(x=1:3, size=12, replace=TRUE),
g=gl(4,3,labels=letters[1:4]), m=gl(3,4,labels=LETTERS[1:3]))

# SQL-OLAP: sum() over (partition by g)
DoBy(d.frm$x, d.frm$g, FUN=sum)
# DoBy(d.frm$x, FUN=sum)

# more than 1 grouping variables are organized as list as in tapply:
DoBy(d.frm$x, list(d.frm$g, d.frm$m), mean)

# count
d.frm$count <- DoBy(d.frm$x, d.frm$g, length)

# rank
d.frm$rank <- DoBy(d.frm$v, d.frm$g, rank)
d.frm$dense_rank <- DoBy(d.frm$v, d.frm$g, DenseRank)
d.frm$rank_desc <- DoBy(d.frm$x, d.frm$g, function(x) rank(-x))

# row_number
d.frm$row_number <- DoBy(d.frm$v, d.frm$g, function(x) order(x))
d.frm
**DoCall**

**Fast Alternative To The Internal do.call**

**Description**

The `do.call` can be somewhat slow, especially when working with large objects. This function is based upon the suggestions from Hadley Wickham on the R mailing list, see [here](#). Also thanks to Tommy at StackOverflow for suggesting how to handle double and triple colon operators, `::`, further enhancing the function.

**Usage**

```r
DoCall(what, args, quote = FALSE, envir = parent.frame())
```

**Arguments**

- **what**: either a function or a non-empty character string naming the function to be called.
- **args**: a list of arguments to the function call. The names attribute of `args` gives the argument names.
- **quote**: a logical value indicating whether to quote the arguments.
- **envir**: an environment within which to evaluate the call. This will be most useful if what is a character string and the arguments are symbols or quoted expressions.

**Note**

While the function attempts to do most of what `do.call` can it has limitations. It can currently not parse the example code from the original function:

```r
do.call(paste,list(as.name("A"),as.name("B")),quote = TRUE)
```

and the functionality of `quote` has not been thoroughly tested.

**Note**

This is a verbatim copy from Gmisc::fastDoCall.

**Author(s)**

Max Gordon <max@gforge.se>

**Examples**

```r
DoCall("complex", list(imaginary = 1:3))
```

```r
## if we already have a list (e.g. a data frame)
## we need c() to add further arguments
tmp <- expand.grid(letters[1:2], 1:3, c("+", "-"))
DoCall("paste", c(tmp, sep = ""))
```
## examples of where objects will be found.

```r
A <- 2
f <- function(x) print(x^2)
env <- new.env()
assign("A", 10, envir = env)
assign("f", f, envir = env)
f <- function(x) print(x)

f(A) # 2
DoCall("f", list(A)) # 2
DoCall("f", list(A), envir = env) # 4
DoCall(f, list(A), envir = env) # 2
DoCall("f", list(quote(A)), envir = env) # 100
DoCall(f, list(quote(A)), envir = env) # 10
DoCall("f", list(as.name("A")), envir = env) # 100

eval(call("f", A)) # 2
eval(call("f", quote(A))) # 2
eval(call("f", A), envir = env) # 4
eval(call("f", quote(A)), envir = env) # 100
```

### Dot

<table>
<thead>
<tr>
<th>Description</th>
<th>Scalar Product</th>
</tr>
</thead>
<tbody>
<tr>
<td>'dot' or 'scalar' product of vectors or pairwise columns of matrices.</td>
<td></td>
</tr>
</tbody>
</table>

### Usage

```r
Dot(x, y)
```

### Arguments

- **x**: numeric vector or matrix
- **y**: numeric vector or matrix

### Details

Returns the 'dot' or 'scalar' product of vectors or columns of matrices. Two vectors must be of same length, two matrices must be of the same size. If `x` and `y` are column or row vectors, their dot product will be computed as if they were simple vectors.

### Value

A scalar or vector of length the number of columns of `x` and `y`.

### Author(s)

Hans W. Borchers <hwborchers@googlemail.com>
**DrawArc**

**See Also**

Cross

**Examples**

```
Dot(1:5, 1:5) #=> 55
# Length of space diagonal in 3-dim- cube:
sqrt(Dot(c(1,1,1), c(1,1,1))) #=> 1.732051
```

---

**Description**

Draw one or more elliptic (or circular) arcs from theta.1 to theta.2 on an existing plot using classic graphics.

**Usage**

```
DrawArc(x = 0, y = x, rx = 1, ry = rx,
theta.1 = 0, theta.2 = 2*pi, nv = 100,
col = par("col"), lty = par("lty"), lwd = par("lwd"),
plot = TRUE)
```

**Arguments**

- `x`, `y` a vector (or scalar) of xy-coordinates of the center(s) of the arc(s).
- `rx` a scalar or a vector giving the semi-major axis of the ellipse for the arc(s).
- `ry` a scalar or a vector giving the semi-minor axis of the ellipse for the arc(s). Default is radius.x which will result in a circle arc with radius.x.
- `theta.1` a scalar or a vector of starting angles in radians.
- `theta.2` a scalar or a vector of ending angles in radians.
- `nv` number of vertices used to plot the arc. Scalar or vector.
- `col` color for the arc(s). Scalar or vector.
- `lty` line type used for drawing.
- `lwd` line width used for drawing.
- `plot` logical. If TRUE the structure will be plotted. If FALSE only the xy-points are calculated and returned. Use this if you want to combine several geometric structures to a single polygon.

**Details**

All parameters are recycled if necessary.
Be sure to use an aspect ratio of 1 as shown in the example to avoid distortion.
Value

`DrawArc` invisibly returns a list of the calculated coordinates for all shapes.

Author(s)

Andri Signorell <andri@signorell.net>

`DrawCircle`, `polygon`

Examples

```r
curve(sin(x), 0, pi, col="blue", asp=1)
DrawArc(x = pi/2, y = 0, rx = 1, theta.1 = pi/4, theta.2 = 3*pi/4, col="red")
```

---

DrawBand

**Draw Confidence Band**

Description

Draw a (confidence) band. Just a wrapper for polygon.

Usage

```r
DrawBand(x, y, col = SetAlpha("grey", 0.5), border = NA)
```

Arguments

- **x**: a vector or a matrix with x coordinates for the band. If x is given as matrix it must be a $2 \times n$ matrix and the second column will be reversed. x will be recycled in the case y is a 2dimensional matrix.
- **y**: a vector or a matrix with y coordinates for the band. If y is given as matrix it must be a $2 \times n$ matrix and the second column will be reversed. y will be recycled in the case x is a 2dimensional matrix.
- **col**: the color of the band.
- **border**: the border color of the band.

`polygon`
**Examples**

```r
set.seed(18)
x <- rnorm(15)
y <- x + rnorm(15)

new <- seq(-3, 3, 0.5)
pred.w.plim <- predict(lm(y ~ x), newdata=data.frame(x=new), interval="prediction")
pred.w.clim <- predict(lm(y ~ x), newdata=data.frame(x=new), interval="confidence")

plot(y ~ x)
DrawBand(y = c(pred.w.plim[,2], rev(pred.w.plim[,3])),
x=c(new, rev(new)), col= SetAlpha("grey90", 0.5))

# passing y as matrix interface allows more intuitive arguments
DrawBand(y = pred.w.clim[, 2:3],
x = new, col= SetAlpha("grey80", 0.5))

abline(lm(y~x), col="brown")
```

---

**DrawBezier**

*Draw a Bezier Curve*

**Description**

Draw a Bezier curve.

**Usage**

```r
DrawBezier(x = 0, y = x, nv = 100, col = par("col"), lty = par("lty"),
lwd = par("lwd"), plot = TRUE)
```

**Arguments**

- `x, y` a vector of xy-coordinates to define the Bezier curve. Should at least contain 3 points.
- `nv` number of vertices to draw the curve.
- `col` color(s) for the curve. Default is par("fg").
- `lty` line type for borders and shading; defaults to "solid".
- `lwd` line width for borders and shading.
- `plot` logical. If TRUE the structure will be plotted. If FALSE only the xy-points are calculated and returned. Use this if you want to combine several geometric structures to a single polygon.
Details

Bezier curves appear in such areas as mechanical computer aided design (CAD). They are named after P. Bezier, who used a closely related representation in Renault’s UNISURF CAD system in the early 1960s (similar, unpublished, work was done by P. de Casteljau at Citroen in the late 1950s and early 1960s). The 1970s and 1980s saw a flowering of interest in Bezier curves, with many CAD systems using them, and many important developments in their theory. The usefulness of Bezier curves resides in their many geometric and analytical properties. There are elegant and efficient algorithms for evaluation, differentiation, subdivision of the curves, and conversion to other useful representations. (See: Farin, 1993)

Value

DrawBezier invisibly returns a list of the calculated coordinates for all shapes.

DrawBezier( x=c(0,0.5,1), y=c(0,0.5,0), col="blue", lwd=2)
DrawBezier( x=c(0,0.5,1), y=c(0,1,0), col="red", lwd=2)
DrawBezier( x=c(0,0.25,0.5,0.75,1), y=c(0,1,1,1,0), col="darkgreen", lwd=2)

---

DrawCircle

**Draw a Circle**

**Description**

Draw one or several circle on an existing plot.

**Usage**

```r
DrawCircle(x = 0, y = x, r.out = 1, r.in = 0,
theta.1 = 0, theta.2 = 2*pi, border = par("fg"),
col = NA, lty = par("lty"), lwd = par("lwd"),
nv = 100, plot = TRUE)
```
Arguments

- **x, y**: a vector (or scalar) of xy-coordinates for the center(s) of the circle(s).
- **r.out**: a vector (or scalar) of the outer radius of the circle.
- **r.in**: a vector (or scalar) of a potential inner radius of an annulus.
- **theta.1**: a vector (or scalar) of the starting angle(s). The sectors are built counterclockwise.
- **theta.2**: a vector (or scalar) of the ending angle(s).
- **nv**: number of vertices to draw the circle.
- **border**: color for circle borders. The default is par("fg"). Use border = NA to omit borders.
- **col**: color(s) to fill or shade the circle(s) with. The default NA (or also NULL) means do not fill, i.e., draw transparent circles, unless density is specified.
- **lty**: line type for borders and shading; defaults to "solid".
- **lwd**: line width for borders and shading.
- **plot**: logical. If TRUE the structure will be plotted. If FALSE only the points are calculated and returned. Use this option if you want to combine several geometric structures to a polygon.

Details

All geometric arguments will be recycled.

Value

The function invisibly returns a list of the calculated coordinates for all shapes.

`polygon`, `DrawRegPolygon`, `DrawEllipse`, `DrawArc`

Examples

```r
Canvas(xlim = c(-5,5), xpd=TRUE)
cols <- Pal("Helsana")[1:4]

# Draw ring
DrawCircle (r.in = 1, r.out = 5, border="darkgrey", col=SetAlpha(hyellow, 0.2), lwd=2)

# Draw circle
DrawCircle (r.in = 6, border=hspring, lwd=3)

# Draw sectors
gem <- rbind(c(-pi, 0, .25, .5), c(0, pi, 1, 2),
```
DrawEllipse

Draw an Ellipse

Description

Draw one or several ellipses on an existing plot.

Usage

DrawEllipse(x = 0, y = x, radius.x = 1, radius.y = 0.5, rot = 0,
    nv = 100, border = par("fg"), col = par("bg"),
    lty = par("lty"), lwd = par("lwd"), plot = TRUE)
DrawEllipse

Arguments

- **x, y**: the x and y co-ordinates for the centre(s) of the ellipse(s).
- **radius.x**: a scalar or a vector giving the semi-major axis of the ellipse.
- **radius.y**: a scalar or a vector giving the semi-minor axis of the ellipse.
- **rot**: angle of rotation in radians.
- **nv**: number of vertices to draw the ellipses.
- **border**: color for borders. The default is `par("fg")`. Use `border = NA` to omit borders.
- **col**: color(s) to fill or shade the annulus sector with. The default NA (or also NULL) means do not fill (say draw transparent).
- **lty**: line type for borders and shading; defaults to "solid".
- **lwd**: line width for borders and shading.
- **plot**: logical. If TRUE the structure will be plotted. If FALSE only the points are calculated and returned. Use this if you want to combine several geometric structures to a single polygon.

Details

Use `DegToRad` if you want to define rotation angle in degrees.

Value

The function invisibly returns a list of the calculated coordinates for all shapes.

eig <- eigen(m)
eig.val <- sqrt(eig$values)
eig.vec <- eig$vectors
DrawEllipse(x=mean(cars$speed), y=mean(cars$dist), radius.x=eig.val[1], radius.y=eig.val[2], rot=acos(eig.vec[1,1]), border="blue", lwd=3)
```
DrawRegPolygon

Description

Draw a regular polygon with n corners. This is the workhorse function for drawing regular polygons. Drawing a circle can be done by setting the vertices to a value of say 100.

Usage

\[
\text{DrawRegPolygon}(x = 0, y = x, \text{radius.x} = 1, \text{radius.y} = \text{radius.x}, \text{rot} = 0,
  \text{nv} = 3, \text{border} = \text{par("fg")}, \text{col} = \text{par("bg")}, \text{lty} = \text{par("lty")},
  \text{lwd} = \text{par("lwd")}, \text{plot} = \text{TRUE})
\]

Arguments

- **x**, **y**: a vector (or scalar) of xy-coordinates of the center(s) of the regular polygon(s).
- **radius.x**: a scalar or a vector giving the semi-major axis of the ellipse for the polygon(s).
- **radius.y**: a scalar or a vector giving the semi-minor axis of the ellipse for the polygon(s). Default is radius.x which will result in a polygon with radius.x.
- **rot**: angle of rotation in radians.
- **nv**: number of vertices to draw the polygon(s).
- **border**: color for borders. The default is \text{par("fg")}. Use \text{border} = \text{NA} to omit borders.
- **col**: color(s) to fill or shade the shape with. The default \text{NA} (or also \text{NULL}) means do not fill (say draw transparent).
- **lty**: line type for borders and shading; defaults to "solid".
- **lwd**: line width for borders and shading.
- **plot**: logical. If \text{TRUE} the structure will be plotted. If \text{FALSE} only the points are calculated and returned. Use this if you want to combine several geometric structures to a polygon.

Details

All geometric arguments will be recycled.

Value

The function invisibly returns a list of the calculated coordinates for all shapes.

# Calculate circle and hexagon, but do not plot
pts <- DrawRegPolygon(radius.x=c(0.7, 0.5), nv = c(100, 6), plot=FALSE )

# combine the 2 shapes and plot the new structure
polygon(x = unlist(lapply(pts, "[", "x")),
  y=unlist(lapply(pts, "[", "y")), col="green", border=FALSE)
Description

Generate a matrix of dummy codes (class indicators) for a given factor.

Usage

```r
Dummy(x, method = c("treatment", "sum", "helmert", "poly", "full"),
       base = 1, levels = NULL)
```

Arguments

- `x`: factor or vector of classes for cases.
- `method`: defines the method of the contrasts being formed. Can be one out of "treatment", "sum", "helmert", "poly", "full", whereas "treatment" is the default one. Abbreviations are accepted. The option "full" returns a full set of class indicators, say a dummy factor for each level of `x`. Note that this would be redundant for `lm()` and friends!
- `base`: an integer specifying which group is considered the baseline group.
- `levels`: an optional vector of the values (as character strings) that `x` might have taken. The default is the unique set of values taken by `as.character(x)`, sorted into increasing order of `x`. This is directly passed on to `factor`.

Details

For reverting dummy codes see the approach in the examples below.

Value

A matrix with the dummy codes. The number of rows correspond to the number of elements in `x` and the number of columns to the number of its levels - 1, respectively to the number of levels given as argument -1.

When `method = "full"` is chosen the number of columns will correspond to the number of levels.

**DunnettTest**  
*Dunnett’s Test for Comparing Several Treatments With a Control*

**Description**

Performs Dunnett’s test for comparing several treatments with a control.

**Usage**

```r
DunnettTest(x, ...)
```

---

## Default S3 method:
DunnettTest(x, g, control = NULL, conf.level = 0.95, ...)

## S3 method for class 'formula'
DunnettTest(formula, data, subset, na.action, ...)

---
Arguments

- **x**: a numeric vector of data values, or a list of numeric data vectors.
- **g**: a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
- **control**: the level of the control group against which the others should be tested. If there are multiple levels the calculation will be performed for every one.
- **conf.level**: confidence level of the interval.
- **formula**: a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

Details

*DunnettTest* does the post hoc pairwise multiple comparisons procedure.

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use *DunnettTest(x)* to perform the test. If the samples are not yet contained in a list, use *DunnettTest(list(x,...))*.

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list of class c("PostHocTest"), containing one matrix named after the control with columns `diff` giving the difference in the observed means, `lwr.ci` giving the lower end point of the interval, `upr.ci` giving the upper end point and `pval` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "PostHocTest". The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

DunnTest

Dunn’s Test of Multiple Comparisons

Description

Performs Dunn’s test of multiple comparisons using rank sums.

Usage

DunnettTest(x, ...)

## Default S3 method:
DunnettTest(x, g,
          method = c("holm", "hochberg", "hommel", "bonferroni", "BH",
                     "BY", "fdr", "none"),
          alternative = c("two.sided", "less", "greater"),
          out.list = TRUE, ...)

## S3 method for class 'formula'

DunnTest
DunnTest(formula, data, subset, na.action, ...)  

## S3 method for class 'DunnTest'  
print(x, digits =getOption("digits", 3), ...)  

Arguments  

x  
a numeric vector of data values, or a list of numeric data vectors.  
g  
a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.  
method  
the method for adjusting p-values for multiple comparisons. The function is calling p.adjust and this parameter is directly passed through.  
alternative  
a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.  
out.list  
logical, indicating if the results should be printed in list mode or as a square matrix. Default is list (TRUE).  
formula  
a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.  
data  
an optional matrix or data frame (or similar; see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).  
subset  
an optional vector specifying a subset of observations to be used.  
na.action  
a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").  
digits  
controls the number of fixed digits to print.  
...  
further arguments to be passed to or from methods.  

Details  

DunnTest performs the post hoc pairwise multiple comparisons procedure appropriate to follow the rejection of a Kruskal-Wallis test. The Kruskal-Wallis test, being a non-parametric analog of the one-way ANOVA, is an omnibus test of the null hypothesis that none of k groups stochastically dominate one another. Dunn’s test is constructed in part by summing jointly ranked data. The rank sum test, itself a non-parametric analog of the unpaired t-test, is possibly intuitive, but inappropriate as a post hoc pairwise test, because (1) it fails to retain the dependent ranking that produced the Kruskal-Wallis test statistic, and (2) it does not incorporate the pooled variance estimate implied by the null hypothesis of the Kruskal-Wallis test.  

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use DunnTest(x) to perform the test. If the samples are not yet contained in a list, use DunnTest(list(x,...)).  

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.
Value

A list with class "DunnTest" containing the following components:

res an array containing the mean rank differences and the according p-values

## Formula interface.
boxplot(Ozone ~ Month, data = airquality)
DunnTest(Ozone ~ Month, data = airquality)
DurbinWatsonTest

**Description**

Performs the Durbin-Watson test for autocorrelation of disturbances.

**Usage**

```r
DurbinWatsonTest(formula, order.by = NULL,
                  alternative = c("greater", "two.sided", "less"),
                  iterations = 15, exact = NULL, tol = 1e-10, data = list())
```

**Arguments**

- `formula`: a symbolic description for the model to be tested (or a fitted "lm" object).
- `order.by`: Either a vector `z` or a formula with a single explanatory variable like `~ z`. The observations in the model are ordered by the size of `z`. If set to `NULL` (the default) the observations are assumed to be ordered (e.g., a time series).
- `alternative`: a character string specifying the alternative hypothesis.
- `iterations`: an integer specifying the number of iterations when calculating the p-value with the "pan" algorithm.
- `exact`: logical. If set to `FALSE` a normal approximation will be used to compute the p value, if `TRUE` the "pan" algorithm is used. The default is to use "pan" if the sample size is < 100.
- `tol`: tolerance. Eigenvalues computed have to be greater than `tol` to be treated as non-zero.
- `data`: an optional data frame containing the variables in the model. By default the variables are taken from the environment which `DurbinWatsonTest` is called from.

**Details**

The Durbin-Watson test has the null hypothesis that the autocorrelation of the disturbances is 0. It is possible to test against the alternative that it is greater than, not equal to, or less than 0, respectively. This can be specified by the `alternative` argument.

Under the assumption of normally distributed disturbances, the null distribution of the Durbin-Watson statistic is the distribution of a linear combination of chi-squared variables. The p-value is computed using the Fortran version of Applied Statistics Algorithm AS 153 by Farebrother (1980, 1984). This algorithm is called "pan" or "gradsol". For large sample sizes the algorithm might fail to compute the p value; in that case a warning is printed and an approximate p value will be given; this p value is computed using a normal approximation with mean and variance of the Durbin-Watson test statistic.

Examples can not only be found on this page, but also on the help pages of the data sets `bondyield`, `currencysubstitution`, `growthofmoney`, `moneydemand`, `unemployment`, `wages`.

For an overview on R and econometrics see Racine & Hyndman (2002).
**Value**

An object of class "htest" containing:

- **statistic** the test statistic.
- **p.value** the corresponding p-value.
- **method** a character string with the method used.
- **data.name** a character string with the data name.

**Note**

This function was previously published as `dwtest` in the **lmtest** package and has been integrated here without logical changes.

DurbinWatsonTest(e_t ~ 1)

---

### Shannon Entropy and Mutual Information

#### Description
Computes Shannon entropy and the mutual information of two variables. The entropy quantifies the expected value of the information contained in a vector. The mutual information is a quantity that measures the mutual dependence of the two random variables.

#### Usage

Entropy(x, y = NULL, base = 2, ...)

MutInf(x, y, base = 2, ...)

#### Arguments

- **x**: a vector or a matrix of numerical or categorical type. If only x is supplied it will be interpreted as contingency table.
- **y**: a vector with the same type and dimension as x. If y is not NULL then the entropy of table(x,y,...) will be calculated.
- **base**: base of the logarithm to be used, defaults to 2.
- **...**: further arguments are passed to the function `table`, allowing i.e. to set `useNA`.

#### Details
The Shannon entropy equation provides a way to estimate the average minimum number of bits needed to encode a string of symbols, based on the frequency of the symbols. It is given by the formula \( H = - \sum (\pi \log(\pi)) \) where \( \pi \) is the probability of character number i showing up in a stream of characters of the given "script". The entropy is ranging from 0 to Inf.
Entropy

Value

a numeric value.

**ErrBars**

## find!

---

**Add Error Bars to an Existing Plot**

### Description

Add error bars to an existing plot.

### Usage

```
ErrBars(from, to = NULL, pos = NULL, mid = NULL, horiz = FALSE, col = par("fg"),
  lty = par("lty"), lwd = par("lwd"), code = 3, length = 0.05,
  pch = NA, cex.pch = par("cex"), col.pch = par("fg"), bg.pch = par("bg"),
  ...)```

### Arguments

- **from** coordinates of points from which to draw (the lower end of the error bars). If to is left to NULL and from is a \( k \times 2 \) dimensional matrix, the first column will be interpreted as from and the second as to.
- **to** coordinates of points to which to draw (the upper end of the error bars).
- **pos** numeric, position of the error bars. This will either be the x-coordinate in case of vertical error bars and the y-coordinate in case of horizontal error bars.
- **mid** numeric, position of midpoints. Defaults to the mean of from and to.
- **horiz** logical, determining whether horizontal error bars are needed (default is FALSE).
- **col** the line color.
- **lty** the line type.
- **lwd** line width.
- **code** integer code, determining where end lines are to be drawn. code = 0 will draw no end lines, code = 1 will draw an end line on the left (lower) side at \((x0[i], y0[i])\), code = 2 on the right (upper) side \((x1[i], y1[i])\) and code = 3 (default) will draw end lines at both ends.
- **length** the length of the end lines.
- **pch** plotting character for the midpoints. The position of the points is given by mid. If mid is left to NULL the points will be plotted in the middle of from and to. No points will be plotted if this is set to NA, which is the default.
- **cex.pch** the character extension for the plotting characters. Default is par("cex").
- **col.pch** the color of the plotting characters. Default is par("fg").
- **bg.pch** the background color of the plotting characters (if pch is set to 21:25). Default is par("bg").
- **...** the dots are passed to the arrows function.
Details

A short wrapper for plotting error bars by means of *arrows*.

# just on one side
b <- barplot(1:5, ylim=c(0,6))
ErrBars(from=1:5, to=1:5+rep(0.5,5), pos=b, length=0.2, col="red", code=2, lwd=2)

b <- barplot(1:5, xlim=c(0,6), horiz=TRUE)
ErrBars(from=1:5, to=1:5+rep(0.2,5), pos=b, horiz=TRUE, length=0.2, col="red", code=2, lwd=2)

par(xpd=FALSE)
dotchart(1:5, xlim=c(0,6))
ErrBars(from=1:5-rep(0.2,5), to=1:5+rep(0.2,5), horiz=TRUE, length=0.1)
```

---

**EtaSq**

*Effect Size Calculations for ANOVAs*

Description

Calculates eta-squared, partial eta-squared and generalized eta-squared

Usage

```r
EtaSq(x, type = 2, anova = FALSE)
```

### S3 method for class 'lm'

```r
EtaSq(x, type = 2, anova = FALSE)
```

### S3 method for class 'aovlist'

```r
EtaSq(x, type = 2, anova = FALSE)
```
**Arguments**

- **x**: An analysis of variance (aov, aovlist) object.
- **type**: What type of sum of squares to calculate? `EtaSq.aovlist` requires `type=1`.
- **anova**: Should the full ANOVA table be printed out in addition to the effect sizes?

**Details**

Calculates the eta-squared, partial eta-squared, and generalized eta-squared measures of effect size that are commonly used in analysis of variance. The input `x` should be the analysis of variance object itself. For between-subjects designs, generalized eta-squared equals partial eta-squared. The reported generalized eta-squared for repeated-measures designs assumes that all factors are manipulated, i.e., that there are no measured factors like gender (see references).

For unbalanced designs, the default in `EtaSq` is to compute Type II sums of squares (`type=2`), in keeping with the `Anova` function in the `car` package. It is possible to revert to the Type I SS values (`type=1`) to be consistent with `anova`, but this rarely tests hypotheses of interest. Type III SS values (`type=3`) can also be computed. `EtaSq.aovlist` requires `type=1`.

**Value**

If `anova=FALSE`, the output for `EtaSq.lm` is an M x 2 matrix, for `EtaSq.aovlist` it is an M x 3 matrix. Each of the M rows corresponds to one of the terms in the ANOVA (e.g., main effect 1, main effect 2, interaction, etc), and each of the columns corresponds to a different measure of effect size. Column 1 contains the eta-squared values, and column 2 contains partial eta-squared values. Column 3 contains the generalized eta-squared values. If `anova=TRUE`, the output contains additional columns containing the sums of squares, mean squares, degrees of freedom, F-statistics and p-values. For `EtaSq.aovlist`, additional columns contain the error sum of squares and error degrees of freedom corresponding to an effect term.

---

**ExpFreq**

**Expected Frequencies**
Description

Calculate the expected frequencies of an n-way table assuming independence.

Usage

ExpFreq(x, freq = c("abs", "rel"))

Arguments

x a table.
freq indicates, whether absolute or relative frequencies should be computed. Can either be "abs" or "rel". Partial matching is supported.

Value

A table with either the absolute or the relative expected frequencies.

Note

This is a copy of the function independence_table in vcd.

---

Extremes Kth Smallest/Largest Values

Description

Find the kth smallest, resp. largest values from a vector x and return the values and their frequencies.

Usage

Small(x, k = 5, unique = FALSE, na.last = NA)
Large(x, k = 5, unique = FALSE, na.last = NA)
HighLow(x, nlow = 5, nhigh = nlow, na.last = NA)
Arguments

- `x`: a numeric vector
- `k`: an integer > 0 defining how many extreme values should be returned. Default is `k = 5`. If `k > length(x)`, all values will be returned.
- `unique`: logical, defining if unique values should be considered or not. If this is set to `TRUE`, a list with the `k` extreme values and their frequencies is returned. Default is `FALSE` (as unique is a rather expensive function).
- `na.last`: for controlling the treatment of `NA`s. If `TRUE`, missing values in the data are put last; if `FALSE`, they are put first; if `NA`, they are removed.
- `nlow`: a single integer. The number of the smallest elements of a vector to be printed. Defaults to 5.
- `nhigh`: a single integer. The number of the greatest elements of a vector to be printed. Defaults to the number of `nlow`.

Details

This does not seem to be a difficult problem at first sight. We could simply tabulate and sort the vector and finally take the first or last `k` values. However sorting and tabulating the whole vector when we're just interested in the few smallest values is a considerable waste of resources. This approach becomes already impracticable for medium vector lengths. There are several points and solutions of this problem discussed out there. The present implementation is based on highly efficient C++ code and proved to be very fast. HighLow enumerates the `k` extreme values (both sides) and their frequencies (in brackets). It is used for describing univariate variables and is interesting for checking the ends of the vector, where in real data often wrong values accumulate. This is merely a printing routine for the highest and the lowest values of `x`.

Value

- if `unique` is set to `FALSE`: a vector with the `k` most extreme values,
- else: a list, containing the `k` most extreme values and their frequencies.

Large(x, 3)
Large(x, k=3, unique=TRUE)

# works fine up to x ~ 1e6
x <- runif(1000000)
Small(x, 3, unique=TRUE)
Small(x, 3, unique=FALSE)

# Both ends
cat(HighLow(d.pizza$temperature, na.last=NA))
```

---

**ExtrVal**  
*Distributions of Maxima and Minima*

**Description**

Density function, distribution function, quantile function and random generation for the maximum/minimum of a given number of independent variables from a specified distribution.

**Usage**

```r
dExtrVal(x, densfun, distnfun, ..., distn, mlen = 1, largest = TRUE, log = FALSE)
pExtrVal(q, distnfun, ..., distn, mlen = 1, largest = TRUE, lower.tail = TRUE)
qExtrVal(p, quantfun, ..., distn, mlen = 1, largest = TRUE, lower.tail = TRUE)
rExtrVal(n, quantfun, ..., distn, mlen = 1, largest = TRUE)
```

**Arguments**

- `x, q`  
  Vector of quantiles.
- `p`  
  Vector of probabilities.
- `n`  
  Number of observations.
- `densfun, distnfun, quantfun`  
  Density, distribution and quantile function of the specified distribution. The density function must have a `log` argument (a simple wrapper can always be constructed to achieve this).
- `...`  
  Parameters of the specified distribution.
- `distn`  
  A character string, optionally given as an alternative to `densfun, distnfun` and `quantfun` such that the density, distribution and quantile functions are formed upon the addition of the prefixes `d, p` and `q` respectively.
- `mlen`  
  The number of independent variables.
largest Logical; if TRUE (default) use maxima, otherwise minima.

log Logical; if TRUE, the log density is returned.

lower.tail Logical; if TRUE (default) probabilities are \(P[X \leq x]\), otherwise \(P[X > x]\).

Value
dExtrVal gives the density function, pExtrVal gives the distribution function and qExtrVal gives the quantile function of the maximum/minimum of \(m\) independent variables from a specified distribution. rExtrVal generates random deviates.

Factorize Prime Factorization of Integers

Description
Compute the prime factorization(s) of integer(s) \(n\).

Usage
Factorize(n)

Arguments
n vector of integers to factorize.

Details
works via Primes, currently in a cheap way, sub-optimal for large composite \(n\).
Value

A named list of the same length as n, each element a 2-column matrix with column "p" the prime factors and column "m" their respective exponents (or multiplities), i.e., for a prime number n, the resulting matrix is cbind(p = n, m = 1).

Author(s)

Martin Maechler, Jan. 1996.

FctArgs

Retrieve a Function’s Arguments

Description

Retrieve a function’s arguments and default values in a list.

Usage

FctArgs(name, sort = FALSE)

Arguments

name

type: character

the name of the function.

sort

type: logical

should the function arguments be sorted? Defaults to FALSE.

Value

a data.frame with the default in the first columns and with row.names as argument names.

FindColor

Get Color on a Defined Color Range

Description

Find a color on a defined color range depending on the value of x. This is helpful for colorcoding numeric values.

Usage

FindColor(x, cols = rev(heat.colors(100)),
          min.x = NULL, max.x = NULL, all.inside = FALSE)

Arguments

  x         numeric.
  cols      a vector of colors.
  min.x     the x-value to be used for the left edge of the first color. If left to the default NULL min(pretty(x)) will be used.
  max.x     the x-value to be used for the right edge of the last color. If left to the default NULL max(pretty(x)) will be used.
  all.inside logical; if true, the returned indices are coerced into 1,...,N-1, i.e., 0 is mapped to 1 and N to N-1.

Details

For the selection of colors the option rightmost.closed in the used function findInterval is set to TRUE. This will ensure that all values on the right edge of the range are assigned a color. How values outside the boundaries of min.x and max.x should be handled can be controlled by all.inside. Set this value to TRUE, if those values should get the colors at the edges or set it to FALSE, if they should remain white (which is the default).

Note that findInterval closes the intervals on the left side, e.g., [0, 1). This option can’t be changed. Consequently will x-values lying on the edge of two colors get the color of the bigger one.

findInterval

Examples

Canvas(7, main="Use of function FindColor()")

# get some data
x <- c(23, 56, 96)
# get a color range from blue via white to red
cols <- colorRampPalette(c("blue","white","red"))(100)
ColorLegend(x="bottomleft", cols=cols, labels=seq(0, 100, 10), cex=0.8)

# and now the color coding of x:
(xcols <- FindColor(x, cols, min.x=0, max.x=100))

# this should be the same as
cols[x+1]

# how does it look like?
y0 <- c(-5, -2, 1)
text(x=1, y=max(y0)+2, labels="Color coding of x:"

text(x=1.5, y=y0, labels=x)
DrawRegPolygon(x=3, y=y0, nv=4, rot=pi/4, col=xcols)
text(x=6, y=y0, labels=xcols)

# how does the function select colors?
Canvas(xlim = c(0,1), ylim = c(0,1))
cols <- c(red="red", yellow="yellow", green="green", blue="blue")
ColorLegend(x=0, y=1, width=1, cols=rev(cols), horiz = TRUE,
    labels=Format(seq(0, 1, .25), digits=2), frame="grey", cex=0.8 )
x <- c(-0.2, 0, 0.15, 0.55, .75, 1, 1.3)
arrows(x0 = x, y0 = 0.6, y1 = 0.8, angle = 15, length = .2)
text(x=x, y = 0.5, labels = x, adj = c(0.5,0.5))
text(x=x, y = 0.4, labels = names(FindColor(x, cols=cols,
    min.x = 0, max.x = 1, all.inside = TRUE)), adj = c(0.5,0.5))
text(x=x, y = 0.3, labels = names(FindColor(x, cols=cols,
    min.x = 0, max.x = 1, all.inside = FALSE)), adj = c(0.5,0.5))

---

FindCorr

Determine Highly Correlated Variables

Description
This function searches through a correlation matrix and returns a vector of integers corresponding to columns to remove to reduce pair-wise correlations.
FindCorr

Usage

FindCorr(x, cutoff = .90, verbose = FALSE)

Arguments

x A correlation matrix
cutoff A numeric value for the pair-wise absolute correlation cutoff
verbose A boolean for printing the details

Details

The absolute values of pair-wise correlations are considered. If two variables have a high correlation, the function looks at the mean absolute correlation of each variable and removes the variable with the largest mean absolute correlation.

There are several function in the subselect package that can also be used to accomplish the same goal. However the package was removed from CRAN and available in the archives.

Value

A vector of indices denoting the columns to remove. If no correlations meet the criteria, numeric(0) is returned.

Author(s)

Original R code by Dong Li, modified by Max Kuhn

References

Examples

corrMatrix <- diag(rep(1, 5))

corrDF <- expand.grid(row = 1:5, col = 1:5)
corrDF$correlation <- as.vector(corrMatrix)

FindCorr(corrMatrix, cutoff = .65, verbose = TRUE)
FindCorr(corrMatrix, cutoff = .99, verbose = TRUE)

# d.pizza example
m <- cor(data.frame(lapply(d.pizza, as.numeric)), use="pairwise.complete.obs")
FindCorr(m, verbose = TRUE)
FisherZ

Fisher-Transformation for Correlation to z-Score

Description

Convert a correlation to a z score or z to r using the Fisher transformation or find the confidence intervals for a specified correlation.

Usage

FisherZ(rho)
FisherZinv(z)
CorCI(rho, n, conf.level = 0.95, alternative = c("two.sided", "less", "greater"))

Arguments

rho
the Pearson’s correlation coefficient
z
a Fisher z transformed value
n
sample size used for calculating the confidence intervals
alternative
is a character string, one of "greater", "less", or "two.sided", or the initial letter of each, indicating the specification of the alternative hypothesis. "greater" corresponds to positive association, "less" to negative association.
conf.level
confidence level for the returned confidence interval, restricted to lie between zero and one.

Details

The sampling distribution of Pearson’s r is not normally distributed. Fisher developed a transformation now called "Fisher’s z-transformation" that converts Pearson’s r’s to the normally distributed variable z’. The formula for the transformation is:

\[ z_r = tanh^{-1} \left( \frac{1 + r}{1 - r} \right) \]

Value

z value corresponding to r (in FisherZ)

r corresponding to z (in FisherZinv)
rho, lower and upper confidence intervals (CorCI)

rc <- t(sapply(r, CorCI, n=n))
t <- r * sqrt(n-2) / sqrt(1-r^2)
p <- (1 - pt(t, n-2)) / 2

r.rc <- data.frame(r=r, z=FisherZ(r), lower=rc[,2], upper=rc[,3], t=t, p=p)

round(r.rc,2)

FixToTable

Convert a Text to a Table

Description

Convert a text to a table by using complete columns of spaces (or any other separator) as delimiting point.

Usage

FixToTable(txt, sep = " ", delim = "\t", trim = TRUE, header = TRUE)

Arguments

txt  the text to be partitioned. Works best, if txt is a matrix.
sep  the separator to use. Will frequently be " ".
delim the new delimiter to insert. (default tab)
trim  logical. Should the separated text be trimmed from whitespace? Defaults to TRUE.
header  logical. Should the first line be interpreted as header?

Details

Only a complete appearance of the separator character in the same position over all rows will be accepted as column delimiter.
Value

a matrix of the separated text.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

# let's get some tabbed text
txt <- matrix(capture.output(Titanic[,,2,1]))
FixToTable(txt[-1,])

Format

Format Numbers and Dates

Description

Formatting numbers in R often degenerates into a major intellectual challenge for us little minds down here in the Valley of Tears. We have several functions available and quite often it's hard to work out which one to use, when an uncommon option is needed. This function wraps those functions and tries to offer a simpler, less technical, but still flexible interface.

There's also an easygoing interface for format templates, defined as a list consisting of any accepted format features. In this way templates can be defined outside and may easily be changed or modified later.

Usage

Format(x, digits = NULL, sci = NULL, big.mark = NULL,
      leading = NULL, zero.form = NULL, na.form = NULL,
      fmt = NULL, align = NULL, width = NULL, lang = NULL,
      eps = .Machine$double.eps, ...)

## S3 method for class 'table'
Format(x, digits = NULL, sci = NULL, big.mark = NULL,
      leading = NULL, zero.form = NULL, na.form = NULL,
      fmt = NULL, align = NULL, width = NULL, lang = NULL,
      eps = .Machine$double.eps, ...)

## S3 method for class 'matrix'
Format(x, digits = NULL, sci = NULL, big.mark = NULL,
      leading = NULL, zero.form = NULL, na.form = NULL,
      fmt = NULL, align = NULL, width = NULL, lang = NULL,
## Default S3 method:
Format(x, digits = NULL, sci = NULL, big.mark = NULL,
  leading = NULL, zero.form = NULL, na.form = NULL,
  fmt = NULL, align = NULL, width = NULL, lang = NULL,
  eps = .Machine$double.eps, ...)

Fmt(...)
as.fmt(...)
as.CDateFmt(fmt)

### Arguments

- **x**
an atomic numerical, typically a vector of real numbers or a matrix of numerical values. Factors will be converted to strings.

- **digits**
integer, the desired (fixed) number of digits after the decimal point. Unlike `formatC` you will always get this number of digits even if the last digit is 0.

- **sci**
integer. The power of 10 to be set when deciding to print numeric values in exponential notation. Fixed notation will be preferred unless the number is larger than 10^{scipen}. If just one value is set it will be used for the left border 10^{-scipen} as well as for the right one (10^{scipen}). A negative and a positive value can also be set independently. Default is `getOption("scipen")`, whereas `scipen=0` is overridden.

- **big.mark**
character; if not empty used as mark between every 3 decimals before the decimal point. Default is "" (none).

- **leading**
character string that can be used for setting leading zeros. "000" would make sure that at least 3 digits on the left side will be printed. Setting leading to "drop" will yield results like ".452" for 0.452. The default NULL will leave the numbers as they are.

- **zero.form**
character, string specifying how zeros should be specially formatted. Useful for pretty printing 'sparse' objects. If set to NULL (default) no special action will be taken.

- **na.form**
character, string specifying how NAs should be specially formatted. If set to NULL (default) no special action will be taken.

- **fmt**
either a format string, allowing to flexibly define special formats or an object of class fmt, consisting of a list of Format arguments. See Details.

- **align**
the character on whose position the strings will be aligned. Left alignment can be requested by setting `sep = "\l"`, right alignment by "\r" and center alignment by "\c". Mind the backslashes, as if they are omitted, strings would be aligned to the character l, r or c respectively. The default is NULL which would just leave the strings as they are.
   This argument is send directly to the function `StrAlign()` as argument sep.

- **width**
integer, the defined fixed width of the strings.
lang

optional value setting the language for the months and daynames. Can be either "local" for current locale or "engl" for english. If left to NULL, the DescToolsOption "lang" will be searched for and if not found "local" will be taken as default.

eps

a numerical tolerance used mainly for formatting p values, those less than eps are formatted as "< [eps]" (where '[eps]' stands for format(eps,digits)).

Details

Format() is used to format numbers. Fmt() can be used to display existing or define new format templates. as.fmt() will convert a list to a format object (class fmt).

The argument fmt can be used be used to generate different formats. When x is a date, it can be formatted with any combination of the format codes d, m and y for day, month or year. Repeting the specific code defines the degree of abbreviation:

Date codes

d  day of the month without leading zero (1 - 31)

dd  day of the month with leading zero (01 - 31)

ddd  abbreviated name for the day of the week (e.g. Mon) in the current user’s language

dddd  full name for the day of the week (e.g. Monday) in the current user’s language

m  month without leading zero (1 - 12)

mm  month with leading zero (01 - 12)

mmm  abbreviated month name (e.g. Jan) in the current user’s language

mmm  full month name (e.g. January) in the current user’s language

y  year without century, without leading zero (0 - 99)

yy  year without century, with leading zero (00 - 99)

yyyy  year with century. For example: 2005

For numeric values there are the following special codes:

Code

e  scientific  forces scientific representation of x, e.g. 3.141e-05. The number of digits, alignment and zero values are respected.

eng  engineering  forces scientific representation of x, but only with powers that are a multiple of 3. same as eng, but replaces the exponential representation by codes. See d.prefix. will divide the given number by 100 and append the %-sign (without a separator).

engabb  engineering abbr.  percent

p  p-value  will wrap the function format.pval and return a p-value format.

frac  fractions  will try to convert numbers to fractions. See fractions().

*  significance  will produce a significance representation of a p-value consisting of * and ., while the breaks are set according to the used defaults e.g. in lm as
fmt can as well be an object of class fmt consisting of a list out of the arguments above. This allows to store the full format in a variable or as an option and use it as format template subsequently. If we would want to define a format for counts, we could create a list with a big mark and with 0 digits and subsequently call the Format function with this format:

```r
fmt.count <- as.fmt(digits=0, big.mark="'")
```

```r
Format(4231.2, fmt=fmt.count)
```

where the latter returns the same result as if the arguments would have been supplied directly:

```r
Format(4231.2, digits=0, big.mark="'").
```

Finally fmt can also be a function in x, which makes formatting very flexible.

The formats can as well be organized as options. DescToolsOptions("fmt") would display the currently defined formats. The functionFmt() can be used to get, modify and store new formats in dependency of the arguments given. See examples.

Value

the formatted values as characters.

If x was a matrix, then a the result will also be a matrix. (Hope this will not surprise you...)

**Frac**

Fractional Part and Maximal Digits of a Numeric Value

**Description**

Frac() returns the fractional part of a numeric value. MaxDigits() return the number of digits in x. Ndec() returns the number of decimals. Prec() returns the precision of a number x.

**Usage**

Frac(x, dpwr = NA)
MaxDigits(x)
Ndec(x)
The Frechet Distribution

Description

Density function, distribution function, quantile function and random generation for the Frechet distribution with location, scale and shape parameters.

Usage

dFrechet(x, loc=0, scale=1, shape=1, log = FALSE)
pFrechet(q, loc=0, scale=1, shape=1, lower.tail = TRUE)
qFrechet(p, loc=0, scale=1, shape=1, lower.tail = TRUE)
rFrechet(n, loc=0, scale=1, shape=1)
Arguments

- **x, q**: Vector of quantiles.
- **p**: Vector of probabilities.
- **n**: Number of observations.
- **loc, scale, shape**: Location, scale and shape parameters (can be given as vectors).
- **log**: Logical; if TRUE, the log density is returned.
- **lower.tail**: Logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \)

Details

The Frechet distribution function with parameters \( \text{loc} = a \), \( \text{scale} = b \) and \( \text{shape} = s \) is

\[
G(z) = \exp \left\{ -\left( \frac{z-a}{b} \right)^{-s} \right\}
\]

for \( z > a \) and zero otherwise, where \( b > 0 \) and \( s > 0 \).

Value

- `dFrechet` gives the density function, `pFrechet` gives the distribution function, `qFrechet` gives the quantile function, and `rFrechet` generates random deviates.

Author(s)

Alec Stephenson <alec_stephenson@hotmail.com>

- `rGenExtrVal`, `rGumbel`, `rRevWeibull`

Examples

```r
dFrechet(2:4, 1, 0.5, 0.8)
pFrechet(2:4, 1, 0.5, 0.8)
qFrechet(seq(0.9, 0.6, -0.1), 2, 0.5, 0.8)
rFrechet(6, 1, 0.5, 0.8)
p <- (1:9)/10
pFrechet(qFrechet(p, 1, 2, 0.8), 1, 2, 0.8)
## [1] 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9
```
**Description**

Calculates absolute and relative frequencies of a vector \( x \). Continuous (numeric) variables will be cut using the same logic as used by the function `hist`. Categorical variables will be aggregated by `table`. The result will contain single and cumulative frequencies for both, absolute values and percentages.

**Usage**

```r
Freq(x, breaks = hist(x, plot = FALSE)$breaks, include.lowest = TRUE,
   ord = c("level", "desc", "asc", "name"),
   useNA = c("no", "ifany", "always"), ...) 
```

```r
## S3 method for class 'Freq'
print(x, digits = NULL, ...) 
```

**Arguments**

- **x**
  - the variable to be described, can be any atomic type.
- **breaks**
  - either a numeric vector of two or more cut points or a single number (greater than or equal to 2) giving the number of intervals into which \( x \) is to be cut. Default taken from the function `hist()`. This is ignored if \( x \) is not of numeric type.
- **include.lowest**
  - logical, indicating if an \( x[i] \) equal to the lowest (or highest, for right = FALSE) "breaks" value should be included. Ignored if \( x \) is not of numeric type.
- **ord**
  - how should the result be ordered? Default is "level", other choices are 'by frequency' ("descending" or "ascending") or 'by name of the levels' ("name"). The argument can be abbreviated. This is ignored if \( x \) is numeric.
- **useNA**
  - one out of "no", "ifany", "always". Defines whether to include extra NA levels in the table. Defaults to "no" which is the `table()` default too.
- **digits**
  - integer, determining the number of digits used to format the relative frequencies.
- **...**
  - further arguments are passed to the function `cut()`. Use `dig.lab` to control the format of numeric group names. Use the argument `right` to define if the intervals should be closed on the right (and open on the left) or vice versa. In `print.Freq` the dots are not used.

**Details**

If `breaks` is specified as a single number, the range of the data is divided into `breaks` pieces of equal length, and then the outer limits are moved away by 0.1% of the range to ensure that the extreme values both fall within the break intervals. (If \( x \) is a constant vector, equal-length intervals are created that cover the single value.)
Value

an object of type "Freq", which is basically a data.frame with 5 columns (earning a specific print routine), containing the following components:

- **level** factor. The levels of the grouping variable.
- **freq** integer. The absolute frequencies.
- **perc** numeric. The relative frequencies (percent).
- **cumfreq** integer. The cumulative sum of the absolute frequencies.
- **cumperc** numeric. The cumulative sum of the relative frequencies.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

- Freq2D, cut, hist, cumsum, table, prop.table

Examples

```r
data(d.pizza)

# result is a data.frame
d.freq <- Freq(d.pizza$price)
d.freq

# it is printed by default with 3 digits for the percent values,
# but the number of digits can be defined in the print function
print(d.freq, digits=5)

# sorted by frequency
Freq(d.pizza$driver, ord="desc")

# sorted by name, including NAs
Freq(d.pizza$driver, ord="name", useNA="ifany")

# percentages and cumulative frequencies for a vector of count data
Freq(as.table(c(2,4,12,8)))
```

Freq2D

Bivariate (Two-Dimensional) Frequency Distribution

Description

Calculate a frequency distribution for two continuous variables.
Freq2D

Usage

Freq2D(x, ...)

## S3 method for class 'formula'
Freq2D(formula, data, subset, ...)

## Default S3 method:
Freq2D(x, y, n=20, pad=0, dnn=NULL, ...)

Arguments

x a vector of x values, or a data frame whose first two columns contain the x and y values.
y a vector of y values.
formula a formula, such as y~x.
data a data.frame, matrix, or list from which the variables in formula should be taken.
subset an optional vector specifying a subset of observations to be used.
n the desired number of bins for the output, a scalar or a vector of length 2.
pad number of rows and columns to add to each margin, containing only zeros.
dnn the names to be given to the dimensions in the result.
... named arguments to be passed to the default method.

Details

The exact number of bins is determined by the pretty function, based on the value of n. Padding the margins with zeros can be helpful for subsequent analysis, such as smoothing. The print logical flag only has an effect when layout=1.

Value

The layout argument specifies one of the following formats for the binned frequency output:

1. matrix that is easy to read, aligned like a scatterplot.
2. list with three elements (x, y, matrix) that can be passed to various plotting functions.
3. data.frame with three columns (x, y, frequency) that can be analyzed further.

**Examples**

Freq2D(quakes$long, quakes$lat, dnn="")
Freq2D(lat~long, quakes, n=c(10,20), pad=1)

# range(Freq2D(saithe, print=FALSE))

# Layout, plot
# Freq2D(saithe, layout=2)
# Freq2D(saithe, layout=3)
# contour(Freq2D(saithe, layout=2))
# lattice::contourplot(Freq~Bio+HR, Freq2D(saithe,layout=3))

---

**GCD, LCM**

*Greatest Common Divisor and Least Common Multiple*

**Description**

Calculates the greatest common divisor (GCD) and least common multiple (LCM) of all the values present in its arguments.

**Usage**

GCD(..., na.rm = FALSE)
LCM(..., na.rm = FALSE)

**Arguments**

... integer or logical vectors.

na.rm logical. Should missing values (including NaN) be removed?

**Details**

The computation is based on the Euclidean algorithm without using the extended version. The greatest common divisor for all numbers in the integer vector \( x \) will be computed (the multiple GCD).

**Value**

A numeric (integer) value.

**Note**

The following relation is always true:

\[ n \times m = \text{GCD}(n, m) \times \text{LCM}(n, m) \]

**Author(s)**

Dirk Eddelbuettel <edd@debian.org> (RCPP part), Andri Signorell <andri@signorell.net>, originally based on code in package **numbers** by Hans W Borchers <hwborchers@gmail.com>
**GenExtrVal**

The Generalized Extreme Value Distribution

**Description**

Density function, distribution function, quantile function and random generation for the generalized Extreme value (GenExtrVal) distribution with location, scale and shape parameters.

**Usage**

```r
dGenExtrVal(x, loc=0, scale=1, shape=0, log = FALSE)
pGenExtrVal(q, loc=0, scale=1, shape=0, lower.tail = TRUE)
qGenExtrVal(p, loc=0, scale=1, shape=0, lower.tail = TRUE)
rGenExtrVal(n, loc=0, scale=1, shape=0)
```

**Arguments**

- `x, q` Vector of quantiles.
- `p` Vector of probabilities.
- `n` Number of observations.
- `loc, scale, shape` Location, scale and shape parameters; the shape argument cannot be a vector (must have length one).
- `log` Logical; if TRUE, the log density is returned.
- `lower.tail` Logical; if TRUE (default), probabilities are P[X <= x], otherwise P[X > x]
Details

The GenExtrVal distribution function with parameters \( \text{loc} = a \), \( \text{scale} = b \) and \( \text{shape} = s \) is

\[
G(z) = \exp \left[ - \{1 + s(z - a)/b\}^{-1/s} \right]
\]

for \( 1 + s(z - a)/b > 0 \), where \( b > 0 \). If \( s = 0 \) the distribution is defined by continuity. If \( 1 + s(z - a)/b \leq 0 \), the value \( z \) is either greater than the upper end point (if \( s < 0 \)), or less than the lower end point (if \( s > 0 \)).

The parametric form of the GenExtrVal encompasses that of the Gumbel, Frechet and reverse Weibull distributions, which are obtained for \( s = 0 \), \( s > 0 \) and \( s < 0 \) respectively. It was first introduced by Jenkinson (1955).

Value

dGenExtrVal gives the density function, pGenExtrVal gives the distribution function, qGenExtrVal gives the quantile function, and rGenExtrVal generates random deviates.

The Generalized Pareto Distribution

Description

Density function, distribution function, quantile function and random generation for the generalized Pareto distribution (GenPareto) with location, scale and shape parameters.

Usage

\begin{verbatim}
dGenPareto(x, loc=0, scale=1, shape=0, log = FALSE)
pGenPareto(q, loc=0, scale=1, shape=0, lower.tail = TRUE)
qGenPareto(p, loc=0, scale=1, shape=0, lower.tail = TRUE)
rGenPareto(n, loc=0, scale=1, shape=0)
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{x, q} Vector of quantiles.
\item \texttt{p} Vector of probabilities.
\item \texttt{n} Number of observations.
\item \texttt{loc, scale, shape} Location, scale and shape parameters; the shape argument cannot be a vector (must have length one).
\item \texttt{log} Logical; if \texttt{TRUE}, the log density is returned.
\item \texttt{lower.tail} Logical; if \texttt{TRUE} (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$
\end{itemize}

Details

The generalized Pareto distribution function (Pickands, 1975) with parameters $loc = a$, $scale = b$ and $shape = s$ is

$$G(z) = 1 - \left\{ 1 + s(z - a)/b \right\}^{-1/s}$$

for $1 + s(z - a)/b > 0$ and $z > a$, where $b > 0$. If $s = 0$ the distribution is defined by continuity.

Value

\begin{itemize}
\item \texttt{dGenPareto} gives the density function, \texttt{pGenPareto} gives the distribution function, \texttt{qGenPareto} gives the quantile function, and \texttt{rGenPareto} generates random deviates.
\end{itemize}

GeomSn

Geometric Series

Description

A geometric sequence is a sequence, such that each term is given by a multiple of q of the previous one. A geometric series consists out of the sum of all former values of a geometric sequence.

Usage

GeomSn(a1, q, n)

Arguments

a1

the first element of the sequence

q

the factor of the sequence

n

number of elements to include in the sum

Value

the sum as numeric value

Author(s)

Andri Signorell <andri@signorell.net>

**Examples**

GeomSn(a1=3, q=2, n=5)

# calculates the sum of the first 5 elements of the sequence
(gseq <- 3 * (2^(0:5)))
sum(gseq)

GeomSn(a1=3, q=2, n=0:5)

---

| GeomTrans | Geometric Transformations |

**Description**

This function transforms geometric structures by translating, scaling and/or rotating them.

**Usage**

GeomTrans(x, y = NULL, trans = 0, scale = 1, theta = 0)

**Arguments**

- **x, y** vectors containing the coordinates of the vertices of the polygon, which has to be transformed. The coordinates can be passed in a plotting structure (a list with x and y components), a two-column matrix, .... See `xy.coords`.
- **trans** a vector of two values for the translation in x-, resp. y-direction. If only one value is supplied it will be recycled.
- **scale** a vector of two values for the scaling factor in x-, resp. y-direction. If only one value is supplied it will be recycled.
- **theta** angle of the rotation in radians starting from 3 o'clock counterclockwise.

**Value**

The function invisibly returns a list of the coordinates for the transformed shape(s).

polygon(xt)

GetCurrWrd

Get a Handle to a Running Word Instance

Description

Look for a running Word instance and return its handle. NULL is returned if nothing’s found.

Usage

GetCurrWrd()
GetCurrXL()

Value

a handle (pointer) to the running Word, resp. Excel instance.

Note

Closing an instance does not update the value of the pointer. So it may contain an invalid address. Whether the pointer is still valid can be checked by IsValidHwnd.

Note

This does unfortunately not work with RDCOMClient (but it would with rcom)! Any better idea out there?

Author(s)

Andri Signorell <andri@signorell.net>

See Also

GetNewWrd, IsValidHwnd
Examples

```r
## Not run: # Windows-specific example

x <- rnorm(100)

wrd <- GetCurrWrd()

if(IsValidHwnd(wrd)){
  Desc(x, wrd=wrd)
} else {
  print("GetCurrWrd: no running word instance found...")
}

## End(Not run)
```

GetNewWrd

Create a New Word Instance

Description

Start a new instance of Word and return its handle. By means of this handle we can then control the
word application.

WrdKill ends a running MS-Word task.

Usage

```r
GetNewWrd(visible = TRUE, template = "Normal", header = FALSE,
           main = "Descriptive report")

WrdKill()
```

Arguments

- `visible` logical, should Word made visible? Defaults to TRUE.
- `template` the name of the template to be used for creating a new document.
- `header` logical, should a caption and a list of contents be inserted? Default is FALSE.
- `main` the main title of the report

Details

The package `RDCOMClient` reveals the whole VBA-world of MS-Word. So generally speaking
any VBA code can be run fully controlled by R. In practise, it might be a good idea to record a
macro and rewrite the VB-code in R.

Here’s a list of some frequently used commands. Let’s assume we have a handle to the application
and a handle to the current selection defined as:
wrd <- GetNewWrd()
sel <- wrd$Selection()

Then we can access the most common properties as follows:

new document wrd[["Documents"]]
open document wrd[["Documents"]]
save document wrd$ActiveDocument()
quit word wrd$quit()
kill word task WrdKill

normal text Use ToWrd which offers many arguments as fontname, size, color, alignment etc.

simple text sel$TypeText("sed diam nonumy eirmod tempor invidunt ut labore")
heading WrdCaption("My Word-Story", index=1)
insert R output ToWrd(capture.output(str(d.diamonds)))
pagebreak sel$InsertBreak(wdConst$wdPageBreak)
sectionbreak sel$InsertBreak(wdConst$wdSectionBreakContinuous)

move cursor right sel$MoveRight(Unit=wdConst$wdCharacter, Count=2, Extend=wdConst$wdExtend)
goto end sel$EndKey(Unit=wdConst$wdStory)
pagesetup sel[["PageSetup"]][["Bottommargin"]]<- 4 * 72
orientation sel[["PageSetup"]][["Orientation"]]<- wdConst$wdOrientLandscape
add bookmark wrd[["ActiveDocument"]][["Bookmarks"]]

create table WrdTable() which allows to define the table’s geometry
insert caption sel$InsertCaption(Label="Abbildung", TitleAutoText="InsertCaption", Title="My Title")
tables of figures wrd$ActiveDocument()$TablesOfFigures()$Add(Range=sel$range(), 
Caption="Figure")
insert header wview <- wrd[["ActiveWindow"]][["ActivePane"]][["View"]][["SeekView"]]
wview <- ifelse(header, wdConst$wdSeekCurrentPageHeader, wdConst$wdSeekCurrentPageFooter)
ToWrd(x, ..., wrd=wrd)

Value

a handle (pointer) to the created Word instance.

Note

Note that the list of contents has to be refreshed by hand after inserting text (if inserted by header = TRUE).

GetNewXL, GetNewPP

Examples

```r
## Not run: # Windows-specific example

wrd <- GetNewWrd()
Desc(d.pizza[,1:4], wrd=wrd)

wrd <- GetNewWrd(header=TRUE)
Desc(d.pizza[,1:4], wrd=wrd)

# enumerate all bookmarks in active document
for(i in 1:wrd[["ActiveDocument"]][["Bookmarks"]]
$count(){
  print(wrd[["ActiveDocument"]][["Bookmarks"]]
$Item(i)$Name())
}

## End(Not run)
```

---

GetNewXL  

Create a New Excel Instance

**Description**

Start a new instance of Excel and return its handle. This is needed to address the Excel application and objects afterwards.

**Usage**

```r
GetNewXL(visible = TRUE, newdoc = TRUE)
```

**Arguments**

- `visible` logical, should Excel made visible? Defaults to TRUE.
- `newdoc` logical, determining if a new workbook should be created. Defaults to TRUE.

**Details**

Here’s a list of some frequently used commands.

Let’s assume:

```r
xl <- GetNewXL()
```

- `workbooks`  
  ```r
  xl$workbooks()$count()
  ```
- `quit excel`  
  ```r
  xl$quit()
  ```

# get a handle to a new excel instance
xl <- GetNewXL()

## End(Not run)

Gini

Gini Coefficient

Description
Compute the Gini coefficient, the most commonly used measure of inequality.

Usage
Gini(x, n = rep(1, length(x)), unbiased = TRUE,
conf.level = NA, R = 1000, type = "bca", na.rm = FALSE)

Arguments
x
a vector containing at least non-negative elements. The result will be NA, if x
contains negative elements.

n
a vector of frequencies (weights), must be same length as x.

unbiased
logical. In order for G to be an unbiased estimate of the true population value,
calculated gini is multiplied by \( n/(n - 1) \). Default is TRUE. (See Dixon, 1987)

conf.level
confidence level for the confidence interval, restricted to lie between 0 and 1. If
set to TRUE the bootstrap confidence intervals are calculated. If set to NA (default)
no confidence intervals are returned.

R
number of bootstrap replicates. Usually this will be a single positive integer.
For importance resampling, some resamples may use one set of weights and
others use a different set of weights. In this case R would be a vector of integers
where each component gives the number of resamples from each of the rows of
weights.
This is ignored if no confidence intervals are to be calculated.

type
character string representing the type of interval required. The value should be
one out of the c("norm","basic","stud","perc" or "bca").
This argument is ignored if no confidence intervals are to be calculated.

na.rm
logical. Should missing values be removed? Defaults to FALSE.
**Details**

The range of the Gini coefficient goes from 0 (no concentration) to $\sqrt{\frac{n-1}{n}}$ (maximal concentration). The bias corrected Gini coefficient goes from 0 to 1.

The small sample variance properties of the Gini coefficient are not known, and large sample approximations to the variance of the coefficient are poor (Mills and Zandvakili, 1997; Glasser, 1962; Dixon et al., 1987), therefore confidence intervals are calculated via bootstrap re-sampling methods (Efron and Tibshirani, 1997).

Two types of bootstrap confidence intervals are commonly used, these are percentile and bias-corrected (Mills and Zandvakili, 1997; Dixon et al., 1987; Efron and Tibshirani, 1997). The bias-corrected intervals are most appropriate for most applications. This is set as default for the type argument ("bca"). Dixon (1987) describes a refinement of the bias-corrected method known as 'accelerated' - this produces values very closed to conventional bias corrected intervals.

**Value**

If `conf.level` is set to `NA` then the result will be

a single numeric value

and if a `conf.level` is provided, a named numeric vector with 3 elements:

- `gini`: Gini coefficient
- `lwr.ci`: lower bound of the confidence interval
- `upr.ci`: upper bound of the confidence interval

GiniSimpson

Compute Gini-Simpson Coefficient

Description

Calculate the Gini-Simpson coefficient.

Usage

GiniSimpson(x, na.rm = FALSE)

Arguments

x a vector containing at least non-negative elements.
na.rm logical. Should missing values be removed? Defaults to FALSE.
Details

The original Simpson index \( \lambda \) equals the probability that two entities taken at random from the dataset of interest (with replacement) represent the same type. The Simpson index was introduced in 1949 by Edward H. Simpson to measure the degree of concentration when individuals are classified into types. The same index was rediscovered by Orris C. Herfindahl in 1950. The square root of the index had already been introduced in 1945 by the economist Albert O. Hirschman. As a result, the same measure is usually known as the Simpson index in ecology, and as the Herfindahl index or the Herfindahl-Hirschman index (HHI) in economics.

Its transformation \( 1 - \lambda \) therefore equals the probability that the two entities represent different types. This measure is also known in ecology as the probability of interspecific encounter (PIE) and the Gini-Simpson index.

Value

a numeric value.

### Gmean

**Geometric Mean and Standard Deviation**

Description

Calculates the geometric mean, its confidence interval and the geometric standard deviation of a vector \( x \).
Usage

Gmean(x, method = c("classic", "boot"), conf.level = NA,
       sides = c("two.sided","left","right"), na.rm = FALSE, ...)

Gsd(x, na.rm = FALSE)

Arguments

x               a positive numeric vector. An object which is not a vector is coerced (if possible) by as.vector.
method          a vector of character strings representing the type of intervals required. The value should be any subset of the values "classic", "boot". See boot.ci.
conf.level      confidence level of the interval. Default is NA.
sides           a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.
na.rm            logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
...              further arguments are passed to the boot function. Supported arguments are type ("norm", "basic", "stud", "perc", "bca"), parallel and the number of bootstrap replicates R. If not defined those will be set to their defaults, being "basic" for type, option "boot.parallel" (and if that is not set, "no") for parallel and 999 for R.

Details

To compute the geometric mean, \( \log(x) \) is first calculated, before the arithmetic mean and its confidence interval are computed by MeanCI.

So the geometric mean and geometric sd are restricted to positive inputs (because otherwise the answer can have an imaginary component). Hence if any argument is negative, the result will be NA. If any argument is zero, then the geometric mean is zero.

The geometric mean is defined as

\[
\sqrt[n]{x_1 \cdot x_2 \cdot x_3 \cdots x_n}
\]

and its confidence interval is given as \( \exp(MeanCI(\log(x))) \). Use sapply to calculate the measures from data frame, resp. from a matrix.

Value

a numeric value.

sapply(as.data.frame(m), Gmean)

Gompertz

The Gompertz distribution

Description

Density, distribution function, quantile function and random generation for the Gompertz distribution with unrestricted shape.

Usage

dGompertz(x, shape, rate = 1, log = FALSE)
pGompertz(q, shape, rate = 1, lower.tail = TRUE, log.p = FALSE)
qGompertz(p, shape, rate = 1, lower.tail = TRUE, log.p = FALSE)
rGompertz(n, shape = 1, rate = 1)

Arguments

x, q vector of quantiles.
shape, rate vector of shape and rate parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P(X \leq x) \), otherwise, \( P(X > x) \).
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
**Details**

The Gompertz distribution with shape parameter \(a\) and rate parameter \(b\) has probability density function

\[
    f(x|a,b) = b e^{ax} \exp(-b/a(e^{ax} - 1))
\]

For \(a = 0\) the Gompertz is equivalent to the exponential distribution with constant hazard and rate \(b\).

The probability distribution function is

\[
    F(x|a,b) = 1 - \exp(-b/a(e^{ax} - 1))
\]

Thus if \(a\) is negative, letting \(x\) tend to infinity shows that there is a non-zero probability \(1 - \exp(b/a)\) of living forever. On these occasions \(qGompertz\) and \(rGompertz\) will return \(\text{Inf}\).

**Value**

d\text{Gompertz} gives the density, p\text{Gompertz} gives the distribution function, q\text{Gompertz} gives the quantile function, and r\text{Gompertz} generates random deviates.

**Note**

Some implementations of the Gompertz restrict \(a\) to be strictly positive, which ensures that the probability of survival decreases to zero as \(x\) increases to infinity. The more flexible implementation given here is consistent with \text{streg} in Stata.

The functions d\text{Gompertz} and similar available in the package \text{eha} label the parameters the other way round, so that what is called the shape there is called the rate here, and what is called 1 / scale there is called the shape here. The terminology here is consistent with the exponential d\text{exp} and Weibull d\text{weibull} distributions in R.

d\text{exp}
GoodmanKruskalGamma

Goodman Kruskal’s Gamma

Description

Calculate Goodman Kruskal’s Gamma statistic, a measure of association for ordinal factors in a two-way table.
The function has interfaces for a table (matrix) and for single vectors.

Usage

GoodmanKruskalGamma(x, y = NULL, conf.level = NA, ...)

Arguments

x
    a numeric vector or a contingency table. A matrix will be treated as a table.

y
    NULL (default) or a vector with compatible dimensions to x. If y is provided,
    table(x,y,...) is calculated.

conf.level
    confidence level of the interval. If set to NA (which is the default) no confidence intervals will be calculated.

...
    further arguments are passed to the function table, allowing i.e. to set useNA. 
    This refers only to the vector interface.

Details

The estimator of $\gamma$ is based only on the number of concordant and discordant pairs of observations. 
It ignores tied pairs (that is, pairs of observations that have equal values of X or equal values of Y). 
Gamma is appropriate only when both variables lie on an ordinal scale.
It has the range [-1, 1]. If the two variables are independent, then the estimator of gamma tends to be close to zero. For $2 \times 2$ tables, gamma is equivalent to Yule’s Q (YuleQ).
Gamma is estimated by

$$G = \frac{P - Q}{P + Q}$$

where P equals twice the number of concordances and Q twice the number of discordances.

Value

a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

)

GoodmanKruskalGamma(tab, conf.level=0.95)
```

---

### GoodmanKruskalTau

**Goodman Kruskal’s Tau**

**Description**

Calculate Goodman Kruskal’s tau statistic, a measure of association for ordinal factors in a two-way table.

The function has interfaces for a table (matrix) and for single vectors.

**Usage**

```r
GoodmanKruskalTau(x, y = NULL, direction = c("row", "column"), conf.level = NA, ...)
```
Arguments

- **x**: a numeric vector or a table. A matrix will be treated as table.
- **y**: NULL (default) or a vector with compatible dimensions to **x**. If **y** is provided, `table(x, y, ...)` is calculated.
- **direction**: direction of the calculation. Can be "row" (default) or "column", where "row" calculates Goodman Kruskal's tau-a (R|C) ("column dependent").
- **conf.level**: confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
- **...**: further arguments are passed to the function `table`, allowing i.e. to set `useNA`. This refers only to the vector interface.

Details

Goodman-Kruskal tau measures association for cross tabulations of nominal level variables. Goodman-Kruskal tau is based on random category assignment. It measures the percentage improvement in predictability of the dependent variable (column or row variable) given the value of other variables (row or column variables). Goodman-Kruskal tau is the same as Goodman-Kruskal lambda except the calculations of the tau statistic are based on assignment probabilities specified by marginal or conditional proportions. Misclassification probabilities are based on random category assignment with probabilities specified by marginal or conditional proportion.

Goodman Kruskal tau reduces to $\phi^2$ (see: `Phi`) in the 2x2-table case.

Value

- a single numeric value if no confidence intervals are requested,
- and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

GTest

G-Test for Count Data

Description

GTest performs chi-squared contingency table tests and goodness-of-fit tests.

Usage

GTest(x, y = NULL, correct = c("none", "williams", "yates"),
      p = rep(1/length(x), length(x)))

Arguments

x a numeric vector or matrix. x and y can also both be factors.
y a numeric vector; ignored if x is a matrix. If x is a factor, y should be a factor of
the same length.
correct one out of "none" (default), "williams", "yates". See Details.

\( p \) a vector of probabilities of the same length of \( x \). An error is given if any entry of \( p \) is negative.

Details

The G-test is also called "Likelihood Ratio Test" and is asymptotically equivalent to the Pearson ChiSquare-test but not usually used when analyzing 2x2 tables. It is used in logistic regression and loglinear modeling which involves contingency tables. The G-test is also reported in the standard summary of \texttt{Desc} for tables.

If \( x \) is a matrix with one row or column, or if \( x \) is a vector and \( y \) is not given, then a goodness-of-fit test is performed (\( x \) is treated as a one-dimensional contingency table). The entries of \( x \) must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in \( p \), or are all equal if \( p \) is not given.

If \( x \) is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of \( x \) must be non-negative integers. Otherwise, \( x \) and \( y \) must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then G-test is performed on the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

TOI Yates’ correction taken from Mike Camann’s 2x2 G-test function. GOF Yates’ correction as described in Zar (2000)

Value

A list with class "htest" containing the following components:

- statistic the value the chi-squared test statistic.
- parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic, NA if the p-value is computed by Monte Carlo simulation.
- p.value the p-value for the test.
- method a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.
- data.name a character string giving the name(s) of the data.
- observed the observed counts.
- expected the expected counts under the null hypothesis.

Gumbel

The Gumbel Distribution

Description

Density function, distribution function, quantile function and random generation for the Gumbel distribution with location and scale parameters.
Usage

dGumbel(x, loc=0, scale=1, log = FALSE)
pGumbel(q, loc=0, scale=1, lower.tail = TRUE)
qGumbel(p, loc=0, scale=1, lower.tail = TRUE)
rGumbel(n, loc=0, scale=1)

Arguments

  x, q  Vector of quantiles.
  p     Vector of probabilities.
  n     Number of observations.
  loc, scale  Location and scale parameters (can be given as vectors).
  log   Logical; if TRUE, the log density is returned.
  lower.tail  Logical; if TRUE (default), probabilities are P[X <= x], otherwise, P[X > x]

Details

  The Gumbel distribution function with parameters \( loc = a \) and \( scale = b \) is

  \[
  G(z) = \exp \left\{ - \exp \left[ - \left( \frac{z - a}{b} \right) \right] \right\}
  \]

  for all real \( z \), where \( b > 0 \).

Value

  dGumbel gives the density function, pGumbel gives the distribution function, qGumbel gives the quantile function, and rGumbel generates random deviates.

Herfindahl

Concentration Measures

Description

Computes the concentration within a vector according to the specified concentration measure.

Usage

Herfindahl(x, n = rep(1, length(x)), parameter = 1, na.rm = FALSE)

Rosenbluth(x, n = rep(1, length(x)), na.rm = FALSE)

Arguments

x 

a vector containing non-negative elements

n 

a vector of frequencies (weights), must be same length as x.

parameter 

parameter of the concentration measure (if set to NULL the default parameter of the respective measure is used)

na.rm 

logical. Should missing values be removed? Defaults to FALSE.

Value

the value of the concentration measure

Note

The same measure is usually known as the Simpson index in ecology, and as the Herfindahl index or the Herfindahl-Hirschman index (HHI) in economics.

Note

These functions were previously published as conc() in the ineq package and have been integrated here without logical changes. NA and weights support were added.

HexToCol

Identify Closest Match to a Color Given by a Hexadecimal String

Description

Given a color as a hex string #rrggbb, find the closest match in the table of known (named) colors.

Usage

HexToCol(hexstr, method = "rgb", metric = "euclidean")

Arguments

hexstr a color or a vector of colors specified as hexadecimal string of the form "#RRGGBB" or "#RRGGBBAA"
method character string specifying the color space to be used. Can be "rgb" (default) or "hsv".
metric character string specifying the metric to be used for calculating distances between the colors. Available options are "euclidean" (default) and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.

Details

Finds the color with the minimum squared distance in RGB space.

Value

The colorme(s) of the closest match(es) (if more than one).

**HexToRgb**

Convert a Hexstring Color to a Matrix With Three Red/Green/Blue Rows

**Description**

HexToRgb() converts a hexstring color the its red/green/blue representation.

**Usage**

HexToRgb(hex)

**Arguments**

- **hex**
  
  a color or a vector of colors specified as hexadecimal string of the form "#RRGGBB" or "#RRGGBBAA"

**Details**

A hex color is written as a hash character, ",", followed by 3 or 4 hexadecimal numbers, say 6, resp. 8, digits (0-9A-F). The first 3 pairs of digits specify the red, green and blue components. When there are 8 digits, then the last pair is interpreted as alpha channel defining transparency, where 00 represents a fully transparent color and FF represent a fully opaque color. The result will be returned as a matrix having 3 or 4 rows, depending on if the input contained a RRGGBBAA definition or not. No distinction is made between upper and lower case. A missing leading # is tolerated.

**Value**

a matrix with 3 or 4 rows.

**Examples**

ColToHex(c("lightblue", "salmon"))

HexToCol(c("#ADD8E6", "#FA1572"))

HexToCol(Pal("Helsana"))

x <- ColToRgb("darkmagenta")

x[2,] <- x[2,] + 155

RgbToCol(x)
Hmean

# 4-digit representation returns a 4 row matrix
HexToRgb(hex=c("#A52A2ABB","#A52A3B","C52A3B"))

---

Hmean

Harmonic Mean and Its Confidence Interval

Description

Calculates the harmonic mean and its confidence interval of a vector x.

Usage

Hmean(x, method = c("classic", "boot"), conf.level = NA, sides = c("two.sided","left","right"), na.rm = FALSE, ...)

Arguments

x a positive numeric vector. An object which is not a vector is coerced (if possible) by as.vector.
method a vector of character strings representing the type of intervals required. The value should be any subset of the values "classic", "boot". See boot.ci.
conf.level confidence level of the interval. Default is NA.
sides a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.
na.rm logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
... further arguments are passed to the boot function. Supported arguments are type ("norm", "basic", "stud", "perc", "bca"), parallel and the number of bootstrap replicates R. If not defined those will be set to their defaults, being "basic" for type, option "boot.parallel" (and if that is not set, "no") for parallel and 999 for R.
Details
To compute the harmonic mean, \(1/x\) is first calculated, before the arithmetic mean and its confidence interval are computed by MeanCI. The harmonic mean is then the reciprocal of the arithmetic mean of the reciprocals of the values. The same applies to the confidence interval.

The harmonic mean is restricted to strictly positive inputs, if any argument is negative, then the result will be NA. If the lower bound of the confidence interval is not greater than zero, then the confidence interval is not defined, and thus NA will be reported.

Use `sapply` to calculate the measures from data frame, resp. from a matrix.

Value
a numeric value.

**HmsToSec**

*Convert h:m:s To/From Seconds*

Description

HmsToSec - Converts a vector of h:m:s to seconds.
SecToHms - Converts a vector of seconds to h:m:s.
Usage

HmsToSec(x)
SecToHms(x, digits = NULL)

Arguments

x A vector of times in h:m:s (for HmsToSec) or seconds (for SecToHms).
digits the number of digits to use for potential fractions of seconds.

Value

HmsToSec - Returns a vector of times in seconds.
SecToHms - Returns a vector of times in h:m:s format.

\textbf{HoeffD}  \hspace{1cm} Matrix of Hoeffding's D Statistics

Description
Computes a matrix of Hoeffding's (1948) $D$ statistics for all possible pairs of columns of a matrix. $D$ is a measure of the distance between $F(x, y)$ and $G(x)H(y)$, where $F(x, y)$ is the joint CDF of $X$ and $Y$, and $G$ and $H$ are marginal CDFs. Missing values are deleted in pairs rather than deleting all rows of $x$ having any missing variables. The $D$ statistic is robust against a wide variety of alternatives to independence, such as non-monotonic relationships. The larger the value of $D$, the more dependent

---

\textbf{HoeffD}  \hspace{1cm} Matrix of Hoeffding's D Statistics

Description
Computes a matrix of Hoeffding's (1948) $D$ statistics for all possible pairs of columns of a matrix. $D$ is a measure of the distance between $F(x, y)$ and $G(x)H(y)$, where $F(x, y)$ is the joint CDF of $X$ and $Y$, and $G$ and $H$ are marginal CDFs. Missing values are deleted in pairs rather than deleting all rows of $x$ having any missing variables. The $D$ statistic is robust against a wide variety of alternatives to independence, such as non-monotonic relationships. The larger the value of $D$, the more dependent
are $X$ and $Y$ (for many types of dependencies). $D$ used here is 30 times Hoeffding's original $D$, and ranges from -0.5 to 1.0 if there are no ties in the data. `print.HoeffD` prints the information derived by `HoeffD`. The higher the value of $D$, the more dependent are $X$ and $Y$.

**Usage**

```r
HoeffD(x, y)
## S3 method for class 'HoeffD'
print(x, ...)
```

**Arguments**

- `x`: a numeric matrix with at least 5 rows and at least 2 columns (if `y` is absent), or an object created by `HoeffD`
- `y`: a numeric vector or matrix which will be concatenated to `x`
- `...`: ignored

**Details**

Uses midranks in case of ties, as described by Hollander and Wolfe. P-values are approximated by linear interpolation on the table in Hollander and Wolfe, which uses the asymptotically equivalent Blum-Kiefer-Rosenblatt statistic. For $P<.0001$ or $>0.5$, $P$ values are computed using a well-fitting linear regression function in $\log P$ vs. the test statistic. Ranks (but not bivariate ranks) are computed using efficient algorithms (see reference 3).

**Value**

a list with elements $D$, the matrix of $D$ statistics, $n$ the matrix of number of observations used in analyzing each pair of variables, and $P$, the asymptotic $P$-values. Pairs with fewer than 5 non-missing values have the $D$ statistic set to NA. The diagonals of $n$ are the number of non-NA for the single variable corresponding to that row and column.

HosmerLemeshowTest  
Hosmer-Lemeshow Goodness of Fit Tests

Description

The function computes Hosmer-Lemeshow goodness of fit tests for C and H statistic as well as the le Cessie-van Houwelingen-Copas-Hosmer unweighted sum of squares test for global goodness of fit.

Usage

```r
HosmerLemeshowTest(fit, obs, ngr = 10, X, verbose = FALSE)
```

Arguments

- **fit**: numeric vector with fitted probabilities.
- **obs**: numeric vector with observed values.
- **ngr**: number of groups for C and H statistic.
- **X**: covariate(s) for le Cessie-van Houwelingen-Copas-Hosmer global goodness of fit test.
- **verbose**: logical, print intermediate results.

Details

Hosmer-Lemeshow goodness of fit tests are computed; see Lemeshow and Hosmer (1982).
If `X` is specified, the le Cessie-van Houwelingen-Copas-Hosmer unweighted sum of squares test for global goodness of fit is additionally determined; see Hosmer et al. (1997).
Value

A list of tests.

glm

Examples

```r
set.seed(111)

x1 <- factor(sample(1:3, 50, replace = TRUE))
x2 <- rnorm(50)
obs <- sample(c(0,1), 50, replace = TRUE)
fit <- glm(obs ~ x1+x2, family = binomial)

HosmerLemeshowTest(fit = fitted(fit), obs = obs, X = cbind(x1, x2))
```

---

**Description**

Hotelling’s T2 test is the multivariate generalisation of the Student’s t test. A one-sample Hotelling’s T2 test can be used to test if a set of vectors of data (which should be a sample of a single statistical population) has a mean equal to a hypothetical mean. A two-sample Hotelling’s T2 test may be used to test for significant differences between the mean vectors (multivariate means) of two multivariate data sets are different.

**Usage**

```r
HotellingsT2Test(x, ...)
```

## Default S3 method:

```r
HotellingsT2Test(x, y = NULL, mu = NULL, test = "f", ...)```
## S3 method for class 'formula'
HotellingsT2Test(formula, data, subset, na.action, ...)

### Arguments

- **x**: a numeric data frame or matrix.
- **y**: an optional numeric data frame or matrix for the two sample test. If NULL a one sample test is performed.
- **mu**: a vector indicating the hypothesized value of the mean (or difference in means if a two sample test is performed). NULL represents origin or no difference between the groups.
- **test**: if "f", the decision is based on the F-distribution, if "chi" a chi-squared approximation is used.
- **formula**: a formula of the form \( x \sim g \) where \( x \) is a numeric matrix giving the data values and \( g \) a factor with two levels giving the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

### Details

The classical test for testing the location of a multivariate population or for testing the mean difference for two multivariate populations. When `test = "f"` the F-distribution is used for the test statistic and it is assumed that the data are normally distributed. If the chi-square approximation is used, the normal assumption can be relaxed to existence of second moments. In the two sample case both populations are assumed to have the same covariance matrix.

The formula interface is only applicable for the 2-sample tests.

### Value

A list with class 'htest' containing the following components:

- **statistic**: the value of the T2-statistic. (That is the scaled value of the statistic that has an F distribution or a chi-square distribution depending on the value of test).
- **parameter**: the degrees of freedom for the T2-statistic.
- **p.value**: the p-value for the test.
- **null.value**: the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
- **alternative**: a character string with the value 'two.sided'.
- **method**: a character string indicating what type of test was performed.
- **data.name**: a character string giving the name of the data (and grouping vector).

Examples

```r
math.teach <- data.frame(
  teacher = factor(rep(1:2, c(3, 6))),
  satis = c(1, 3, 2, 4, 6, 6, 5, 5, 4),
  know = c(3, 7, 2, 6, 8, 8, 10, 10, 6))

with(math.teach,
  HotellingsT2Test(cbind(satis, know) ~ teacher))
```

HuberM  Safe (generalized) Huber M-Estimator of Location

Description
(Generalized) Huber M-estimator of location with MAD scale, being sensible also when the scale is zero where huber() returns an error.

Usage

```r
HuberM(x, k = 1.345, mu = median(x), s = mad(x, center = mu),
  na.rm = FALSE, conf.level = NA, ci.type = c("wald", "boot"), ...)
```

Arguments

- `x` numeric vector.
- `k` positive factor; the algorithm winsorizes at k standard deviations.
- `mu` initial location estimator.
- `s` scale estimator held constant through the iterations.
- `na.rm` logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
- `conf.level` confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
- `ci.type` The type of confidence interval required. The value should be any subset of the values "wald", "boot".
- `...` the dots are passed to the function boot, when confidence intervals are calculated.
Details

The standard error is computed using the $\tau$ correction factor but no finite sample correction. The original function is not exported, but can be accessed as `DescTools::huberM`.

Value

If `conf.level` is set to `NA` then the result will be

a single numeric value

and if a `conf.level` is provided, a named numeric vector with 3 elements:

- `huberm` the estimate for location
- `lwr.ci` lower bound of the confidence interval
- `upr.ci` upper bound of the confidence interval

Author(s)

Martin Maechler, building on the MASS code mentioned.

x <- c(round(rnorm(1000), 1), round(rnorm(50, m=10, sd = 10)))
HuberM(x, conf.level=0.95)

## Not run:
# scale zero
HuberM(rep(9, 100))
mad (rep(9, 100))

# bootstrap confidence intervals
HuberM(x, conf.level=0.95, ci.type="boot")

## End(Not run)
```
Description

The Intraclass correlation is used as a measure of association when studying the reliability of raters. Shrout and Fleiss (1979) outline 6 different estimates, that depend upon the particular experimental design. All are implemented and given confidence limits.

Usage

ICC(x, type = c("all", "ICC1", "ICC2", "ICC3", "ICC1k", "ICC2k", "ICC3k"),
conf.level = NA, na.rm = FALSE)

## S3 method for class 'ICC'
print(x, digits = 3, ...)

Arguments

x

$n \times m$ matrix or dataframe, k subjects (in rows) m raters (in columns).

type

one out of "all", "ICC1", "ICC2", "ICC3", "ICC1k", "ICC2k", "ICC3k". See details.

conf.level

confidence level of the interval. If set to NA (which is the default) no confidence intervals will be calculated.

na.rm

logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.

digits

number of digits to use in printing

... further arguments to be passed to or from methods.

Details

Shrout and Fleiss (1979) consider six cases of reliability of ratings done by k raters on n targets.

**ICC1** Each target is rated by a different judge and the judges are selected at random. (This is a one-way ANOVA fixed effects model and is found by \((MSB- MSW)/(MSB+ (nr-1)*MSW)\))

**ICC2** A random sample of k judges rate each target. The measure is one of absolute agreement in the ratings. Found as \((MSB- MSE)/(MSB+ (nr-1)*MSE + nr*(MSJ-MSE)/nc)\)

**ICC3** A fixed set of k judges rate each target. There is no generalization to a larger population of judges. \((MSB - MSE)/(MSB+ (nr-1)*MSE)\)

Then, for each of these cases, is reliability to be estimated for a single rating or for the average of k ratings? (The 1 rating case is equivalent to the average intercorrelation, the k rating case to the
Spearman Brown adjusted reliability.)

ICC1 is sensitive to differences in means between raters and is a measure of absolute agreement.

ICC2 and ICC3 remove mean differences between judges, but are sensitive to interactions of raters by judges.

The difference between ICC2 and ICC3 is whether raters are seen as fixed or random effects.

ICC1k, ICC2k, ICC3K reflect the means of k raters.

The intraclass correlation is used if raters are all of the same “class”. That is, there is no logical way of distinguishing them. Examples include correlations between pairs of twins, correlations between raters. If the variables are logically distinguishable (e.g., different items on a test), then the more typical coefficient is based upon the inter-class correlation (e.g., a Pearson r) and a statistic such as alpha or omega might be used.

Value

if method is set to "all", then the result will be

results A matrix of 6 rows and 8 columns, including the ICCs, F test, p values, and confidence limits
summary The anova summary table
stats The anova statistics
MSW Mean Square Within based upon the anova

if a specific type has been defined, the function will first check, whether no confidence intervals are requested: if so, the result will be the estimate as numeric value

else a named numeric vector with 3 elements

ICCx estimate (name is the selected type of coefficient)
lwr.ci lower confidence interval
upr.ci upper confidence interval

Note

The results for the lower and upper Bounds for ICC(2,k) do not match those of SPSS 9 or 10, but do match the definitions of Shrout and Fleiss. SPSS seems to have been using the formula in McGraw and Wong, but not the errata on p 390. They seem to have fixed it in more recent releases (15).

**identify.formula**  
*Identify Points In a Plot Using a Formula*

### Description

The function `identify` reads the position of the graphics pointer when the (first) mouse button is pressed. It then searches the coordinates given in x and y for the point closest to the pointer. If this point is close enough to the pointer, its index will be returned as part of the value of the call.

### Usage

```r
## S3 method for class 'formula'
identify(formula, data, subset, na.action, ...)
```

### Arguments

- **formula**  
a formula of the form `lhs ~ rhs` where `lhs` gives the data values and `rhs` the corresponding groups.

- **data**  
The data frame from which the formula should be evaluated.

- **subset**  
an optional vector specifying a subset of observations to be used.

- **na.action**  
a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

- **...**  
Other arguments to be passed to `identify`.
IdentifyA

Details

This function is meant to make it easier to call identify after plot has been called using a formula and the data argument.

A two dimensional plot must be active and the vectors in x and data frame in data must correspond to the x- and y-axes and the data of the plot.

Value

If pos is FALSE, an integer vector containing the indices of the identified points, in the order they were identified. If pos is TRUE, a list containing a component ind, indicating which points were identified and a component pos, indicating where the labels were placed relative to the identified points (1=below, 2=left, 3=above, 4=right and 0=no offset, used if atpen = TRUE).

identify(dist ~ speed, data = cars, subset = speed < 17)
## End(Not run)

IdentifyA Identify Points in Plot Lying Within a Rectangle or Polygon

Description

Find all the points lying either in a rectangle area spanned by an upper left and a bottom-right point or by a polygon area consisting of any number of points defined by point and click.

Usage

IdentifyA(x, ...)

## S3 method for class 'formula'
IdentifyA(formula, data, subset, poly = FALSE, ...)
## Default S3 method:
IdentifyA(x, y = NULL, poly = FALSE, ...)
Arguments

- **x, y**: x and y values of the points used to create the plot.
- **formula**: a formula, such as y ~ x specifying x and y values. Here the formula must be entered that was used to create the scatterplot.
- **data**: a data frame (or list) from which the variables in formula should be taken.
- **subset**: an optional vector specifying a subset of observations to be used.
- **poly**: logical. Defines if a polygon or a rectangle should be used to select the points. Default is rectangle. If a polygon should be used, set this argument to TRUE and select all desired points. The polygon will be closed automatically when finished.
- **...**: Other arguments to be passed to IdentifyA.

Value

Index vector with the points lying within the selected area. The coordinates are returned as text in the attribute "cond".

## Not run:
# run the example via copy and paste
plot(temperature ~ delivery_min, data=d.pizza)
idx <- IdentifyA(temperature ~ delivery_min, data=d.pizza)

# you selected the following points
d.pizza[idx,]
points(temperature ~ delivery_min, data = d.pizza[idx,], col="green")

# use the attr("cond") for subsets in code
attr(idx, "cond")

# create a group variable for the found points
d.pizza$grp <- seq(nrow(d.pizza)) %in% idx

# try the polygon option
idx <- IdentifyA(temperature ~ delivery_min, data=d.pizza, poly=TRUE)
points(temperature ~ delivery_min, data = d.pizza[idx,], col="red")
```

## End(Not run)
**ImputeKnn**

*Fill in NA values with the values of the nearest neighbours*

**Description**

Function that fills in all NA values using the k Nearest Neighbours of each case with NA values. By default it uses the values of the neighbours and obtains an weighted (by the distance to the case) average of their values to fill in the unknowns. If `meth='median'` it uses the median/most frequent value, instead.

**Usage**

```r
ImputeKnn(data, k = 10, scale = T, meth = "weighAvg",
              distData = NULL)
```

**Arguments**

- `data` : A data frame with the data set
- `k` : The number of nearest neighbours to use (defaults to 10)
- `scale` : Boolean setting if the data should be scale before finding the nearest neighbours (defaults to T)
- `meth` : String indicating the method used to calculate the value to fill in each NA. Available values are `median` or `weighAvg` (the default).
- `distData` : Optionally you may specify here a data frame containing the data set that should be used to find the neighbours. This is useful when filling in NA values on a test set, where you should use only information from the training set. This defaults to NULL, which means that the neighbours will be searched in `data`

**Details**

This function uses the k-nearest neighbours to fill in the unknown (NA) values in a data set. For each case with any NA value it will search for its k most similar cases and use the values of these cases to fill in the unknowns.

If `meth='median'` the function will use either the median (in case of numeric variables) or the most frequent value (in case of factors), of the neighbours to fill in the NAs. If `meth='weighAvg'` the function will use a weighted average of the values of the neighbours. The weights are given by 

\[ \exp(-\text{dist}(k,x)) \]

where \(\text{dist}(k,x)\) is the euclidean distance between the case with NAs (x) and the neighbour k.

**Value**

A data frame without NA values

InDots(..., arg, default)

Description

Returns the value of a specific named argument if it was comprised in the dots or a default value, if it wasn’t.

Usage

InDots(..., arg, default)

Arguments

... the dots arguments to be checked.
arg the name of argument to test for.
default the default value to return, if the argument arg does not exist in the dots.

Value

the value of the argument, if it exists else the specified default value.

Andri Signorell <andri@signorell.net>
The (weighted) Interquartile Range

Description

computes interquartile range of the x values. Weights are supported.

Usage

IQRw(x, weights = NULL, na.rm = FALSE, type = 7)

Arguments

x  a numeric vector.
weights  an optional numeric vector giving the sample weights.
na.rm  logical. Should missing values be removed?
type  an integer selecting one of the many quantile algorithms, see Quantile().

Details

This implementation is based on Quantile() function, which allows to define weights.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

Median(), Quantile(), IQR(), quantile()

Examples

x <- c(3.7, 3.3, 3.5, 2.8)
w <- c(5, 5, 4, 1)/15

IsDate

Check If an Object Is of Type Date

Description

Check if the given x is of any known Date type.

Usage

IsDate(x, what = c("either", "both", "timeVaries"))

Arguments

x          a vector or values to be checked.
what       can be any value out of "either" (default), "both" or "timeVaries".

Details

This checks for many known Date and Time classes: "POSIXt", "POSIXct", "dates", "times", 
"chron", "Date".

Value

logical vector of the same dimension as x.

Author(s)

Frank E Harrell

See Also

Examples

IsDate(as.Date("2013-04-10"))

IsDate(31002)
IsDichotomous

Test if a Variable Contains Only Two Unique Values

Description

Test if a variable contains only two values. The variable does not need to be a numerical value, factors and logicals are supported as well. NAs can be skipped by setting na.rm to TRUE.

Usage

IsDichotomous(x, strict = FALSE, na.rm = FALSE)

Flags(x, na.rm = FALSE)

Arguments

x  a numeric or integer vector, a logical vector or a factor (ordered and unordered)

strict logical. If set to TRUE, the result will only be TRUE, if x contains exactly 2 levels. If set to FALSE the result will be TRUE for 1 and for 2 levels.

na.rm logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.

Details

IsDichotomous tests a single variable. Flags returns the names of all the dichotomous variables in a list or data.frame.

Value

TRUE if x contains only two unique values, FALSE else

Author(s)

Andri Signorell <andri@signorell.net>

Examples

IsDichotomous(sample(10, 5, replace=TRUE))
**Description**

Confirmation of the Euclidean nature of a distance matrix by the Gower’s theorem. 
*IsEuclid* is used in *summary.dist*.

**Usage**

```
IsEuclid(distmat, plot = FALSE, print = FALSE, tol = 1e-07)
```

**Arguments**

- `distmat` an object of class ‘dist’
- `plot` a logical value indicating whether the eigenvalues bar plot of the matrix of the term \(-\frac{1}{2}d_{ij}^2\) centred by rows and columns should be displayed
- `print` a logical value indicating whether the eigenvalues of the matrix of the term \(-\frac{1}{2}d_{ij}^2\) centred by rows and columns should be printed
- `tol` a tolerance threshold: an eigenvalue is considered positive if it is larger than \(-\text{tol}\times\lambda_1\) where \(\lambda_1\) is the largest eigenvalue.

**Value**

returns a logical value indicating if all the eigenvalues are positive or equal to zero

IsOdd

Checks If An Integer Is Even Or Odd

Description
Checks if the elements of an integer vector \(x\) are even or odd.

Usage
\[\text{IsOdd}(x)\]

Arguments
\(x\) vector of integers

Value
a logic vector

Author(s)
Andri Signorell <andri@signorell.net>

See Also
\[\text{IsWhole}\]

Examples
\[\text{IsOdd}(1:10)\]

IsPrime

Description
Returns for a vector or matrix of positive integers a logical object of the same dimension(s) containing TRUE for the elements that are prime and FALSE otherwise.

Usage
\[\text{IsPrime}(x)\]

Arguments
\(x\) vector or matrix of nonnegative integers
IsValidHwnd

Details

Given a vector or a matrix of positive integers returns a vector of the same size of FALSE and TRUE. Use which(IsPrime(1:21)) to get the positions.

Value

logical vector

Author(s)

Hans W. Borchers <hwborchers@googlemail.com>

See Also

Factorize, Primes

Examples

x <- matrix(1:10, nrow=10, ncol=10, byrow=TRUE)
x * IsPrime(x)

# Find first prime number octett:
octett <- c(0, 2, 6, 8, 30, 32, 36, 38) - 19
while (TRUE) {
  octett <- octett + 210
  if (all(IsPrime(octett))) {
    cat(octett, "\n", sep=" ")
    break
  }
}

IsValidHwnd

Check Windows Pointer

Description

Check if a pointer points to a valid and running MS-Office instance. The function does this by first checking for NULL and nil pointer and then trying to get the current selection of the application.

Usage

IsValidHwnd(hwnd)

Arguments

hwnd the pointer to a word instance as created by GetNewWrd() or GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions("lastWord").
JarqueBeraTest

Value

logical value, TRUE if hwnd is a valid pointer to a running application

Author(s)

Andri Signorell <andri@signorell.net>

See Also

GetCurrWrd(), GetCurrXL(), GetCurrPP()

Description

This function performs the Jarque-Bera tests of normality either the robust or the classical way.

Usage

JarqueBeraTest(x, robust = TRUE, method = c("chisq", "me"),
               N = 0, na.rm = FALSE)

Arguments

x       a numeric vector of data values.
robust  defines, whether the robust version should be used. Default is TRUE.
method  a character string out of chisq or mc, specifying how the critical values should
         be obtained. Default is approximated by the chisq-distribution or empirically
         via Monte Carlo.
N       number of Monte Carlo simulations for the empirical critical values
na.rm  defines if NAs should be omitted. Default is FALSE.

Details

The test is based on a joint statistic using skewness and kurtosis coefficients. The robust Jarque-
Bera (RJB) version of utilizes the robust standard deviation (namely the mean absolute deviation
from the median, as provided e. g. by MeanAD(x,FUN=median)) to estimate sample kurtosis and
skewness. For more details see Gel and Gastwirth (2006).
Setting robust to FALSE will perform the original Jarque-Bera test (see Jarque, C. and Bera, A
(1980)).
Value

A list with class htest containing the following components:

- statistic: the value of the test statistic.
- parameter: the degrees of freedom.
- p.value: the p-value of the test.
- method: type of test was performed.
- data.name: a character string giving the name of the data.

Note

This function is melted from the jarque.bera.test (in tseries package) and the rjb.test from the package lawstat.

JonckheereTerpstraTest

Exact Version of Jonckheere-Terpstra Test

Description
Jonckheere-Terpstra test to test for ordered differences among classes.

Usage
JonckheereTerpstraTest(x, ...)

## Default S3 method:
JonckheereTerpstraTest(x, g, alternative = c("two.sided", "increasing", "decreasing"),
nperm = NULL, ...)

## S3 method for class 'formula'
JonckheereTerpstraTest(formula, data, subset, na.action, ...)

Arguments
- **x**: a numeric vector of data values, or a list of numeric data vectors.
- **g**: a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
- **alternative**: means are monotonic (two.sided), increasing, or decreasing
- **nperm**: number of permutations for the reference distribution. The default is NULL in which case the permutation p-value is not computed. It's recommended to set nperm to 1000 or higher if permutation p-value is desired.
- **formula**: a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
- **...**: further argument to be passed to methods.

Details
JonckheereTerpstraTest is the exact (permutation) version of the Jonckheere-Terpstra test. It uses the statistic
\[ \sum_{k<l} \sum_{ij} I(X_{ik} < X_{jl}) + 0.5I(X_{ik} = X_{jl}), \]
where \(i, j\) are observations in groups \(k\) and \(l\) respectively. The asymptotic version is equivalent to `cor.test(x, g, method="k")`. The exact calculation requires that there be no ties and that the sample size is less than 100. When data are tied and sample size is at most 100 permutation p-value is returned.

If \(x\) is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, \(g\) is ignored, and one can simply use `JonckheereTerpstraTest(x)` to perform the test. If the samples are not yet contained in a list, use `JonckheereTerpstraTest(list(x, ...))`.

Otherwise, \(x\) must be a numeric data vector, and \(g\) must be a vector or factor object of the same length as \(x\) giving the group for the corresponding elements of \(x\).

**Note**

The function was previously published as `jonckheere.test()` in the `clinfun` package and has been integrated here without logical changes. Some argument checks and a formula interface were added.

  grp=Utable(c(4,6,5), type="ordered")[,1]
)
```
KappaM

Kappa for m Raters

Description

Computes kappa as an index of interrater agreement between m raters on categorical data.

Usage

KappaM(x, method = c("Fleiss", "Conger", "Light"), conf.level = NA)

Arguments

x

n × m matrix or dataframe, n subjects m raters.

method

a logical indicating whether the exact Kappa (Conger, 1980), the Kappa described by Fleiss (1971) or Light’s Kappa (1971) should be computed.

conf.level

confidence level of the interval. If set to NA (which is the default) no confidence intervals will be calculated.

Details

Missing data are omitted in a listwise way.

The coefficient described by Fleiss (1971) does not reduce to Cohen’s Kappa (unweighted) for m=2 raters. Therefore, the exact Kappa coefficient, which is slightly higher in most cases, was proposed by Conger (1980).

Light’s Kappa equals the average of all possible combinations of bivariate Kappas between raters. The confidence levels can only be reported using Fleiss’ formulation of Kappa.

Value

a single numeric value if no confidence intervals are requested,

and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

Note

This function was previously published as kappam.fleiss() in the irr package and has been integrated here with some changes in the interface.

<table>
<thead>
<tr>
<th>KendallTauA</th>
<th>Kendall's τ_a</th>
</tr>
</thead>
</table>

Description

Calculate Kendall's tau-a statistic, a measure of association for ordinal factors in a two-way table. The function has interfaces for a table (matrix) and for single vectors.

Usage

KendallTauA(x, y = NULL, direction = c("row", "column"), conf.level = NA, ...)

Arguments

- **x**: a numeric vector or a table. A matrix will be treated as table.
- **y**: NULL (default) or a vector with compatible dimensions to x. If y is provided, `table(x,y,...)` is calculated.
- **direction**: direction of the calculation. Can be "row" (default) or "column", where "row" calculates Kendall’s tau-a (RIC) ("column dependent").
- **conf.level**: confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
- **...**: further arguments are passed to the function `table`, allowing i.e. to set useNA. This refers only to the vector interface.

Details

Kendall’s tau coefficient (sometimes called "Kendall rank correlation coefficient"), is a statistic used to measure the association between two measured quantities. It is a measure of rank correlation: the similarity of the orderings of the data when ranked by each of the quantities.

Kendall’s tau-a is computed as

\[ \tau_a(C|R) = \frac{P - Q}{\frac{1}{2} \cdot n \cdot (n - 1)} \]

where P equals twice the number of concordances and Q twice the number of discordances. Its range is [-1, 1].

(Note that Kendall tau-a does not take into consideration any ties, which makes it unpractical. Consider using `KendallTauB` (Tau-b) when ties are present.)

Value

- a single numeric value if no confidence intervals are requested,
- and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

KendallTauA(x, y, conf.level=0.95)
```

---

**KendallTauB**

*Kendall’s τ_b*

**Description**

Calculate Kendall’s tau-b. The estimator could also be calculated with cor(...,method="kendall"). The calculation of confidence intervals however would not be found there.

**Usage**

KendallTauB(x, y = NULL, conf.level = NA, ...)
Arguments

x  
a numeric vector, matrix or data.frame.

y  
NULL (default) or a vector with compatible dimensions to x. If y is provided, table(x,y,...) is calculated.

conf.level  
confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.

...  
further arguments are passed to the function table, allowing i.e. to set useNA. This refers only to the vector interface.

Value

da single numeric value if no confidence intervals are requested, and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

KendallTauB(tab, conf.level=0.95)
KendallW

Kendall’s Coefficient of Concordance W

Description

Computes Kendall’s coefficient of concordance, a popular measure of association. It is an index of interrater reliability of ordinal data. The coefficient could be corrected for ties within raters.

Usage

KendallW(x, correct = FALSE, test = FALSE, na.rm = FALSE)

Arguments

x

n \times m\ matrix or dataframe, k subjects (in rows) m raters (in columns).

correct

a logical indicating whether the coefficient should be corrected for ties within raters.

test

a logical indicating whether the test statistic and p-value should be reported.

na.rm

logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE only the complete cases of the ratings will be used. Defaults to FALSE.

Details

The test for Kendall’s W is completely equivalent to friedman.test. The only advantage of this test over Friedman’s is that Kendall’s W has an interpretation as the coefficient of concordance. The test itself is only valid for large samples. Kendall’s W should be corrected for ties, if raters did not use a true ranking order for the subjects.

Value

Either a single value if test is set to FALSE or else

a list with class “htest” containing the following components:

 statistic the value of the chi-square statistic.
 p.value the p-value for the test.
 method the character string “Kendall’s coefficient of concordance W”.
 data.name a character string giving the name(s) of the data.
 estimate the coefficient of concordance.
 parameter the degrees of freedom df, the number of subjects examined and the number of raters.
Note

This function was previously published as kendall() in the \texttt{irr} package and has been integrated here without logical changes, but with some adaptations in the result structure.

KrippAlpha

Krippendorff's Alpha Reliability Coefficient

Description

Calculate the alpha coefficient of reliability proposed by Krippendorff.

Usage

KrippAlpha(x, method=c("nominal", "ordinal", "interval", "ratio"))

Arguments

- x: classifier x object matrix of classifications or scores
- method: data level of x

Value

A list with class "irrlist" containing the following components:

- method: a character string describing the method.
- subjects: the number of data objects.
- raters: the number of raters.
- irr.name: a character string specifying the name of the coefficient.
- value: value of alpha.
- stat.name: here "nil" as there is no test statistic.
- statistic: the value of the test statistic (NULL).
- p.value: the probability of the test statistic (NULL).
- cm: the concordance/discordance matrix used in the calculation of alpha
- data.values: a character vector of the unique data values
- levx: the unique values of the ratings
- nmatchval: the count of matches, used in calculation
- data.level: the data level of the ratings ("nominal","ordinal", "interval","ratio")

Note

Krippendorff's alpha coefficient is particularly useful where the level of measurement of classification data is higher than nominal or ordinal.

Note

This function was previously published as kripp.alpha() in the irr package and has been integrated here without logical changes, but with some adaptations in the result structure.

Jim Lemon <jim@bitwrit.com.au>

References

Examples
```r
# the "C" data from Krippendorff
nmm <- matrix(c(1,1,NA,1,2,2,3,3,3,3,3,3,2,2,1,2,3,4,4,4,4,4, 1,1,2,1,2,2,2,2,NA,5,5,5,NA,NA,1,1,NA,NA,3,NA), nrow=4)

# first assume the default nominal classification
KrippAlpha(nmm)

# now use the same data with the other three methods
KrippAlpha(nmm, "ordinal")
KrippAlpha(nmm, "interval")
KrippAlpha(nmm, "ratio")
```

Description
Set and retrieve the label, resp. unit attribute of `x`. This can be helpful for documenting the specific meaning of a variable, of an entire data.frame or any other object. For single vectors it can be useful to store the unit.

Usage
```r
Label(x)
Label(x) <- value

Unit(x)
Unit(x) <- value
```

Arguments
- `x` any object
- `value` a single string describing the object

Details
The label should consist of a single text (length of 1). The text may contain line feeds. It can be deleted by setting the label to `NULL`.
Lambda

**Value**

Label and Unit return the label attribute of x, if any; otherwise, NULL.

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

A more elaborated label version can be found in package Hmisc label().

**Examples**

```r
# add a descriptive label to a variable
Label(d.diamonds$colour) <- "The rating scale applied to diamonds ranges from colorless to yellow, as any other color is extremely rare."

# technically just appending the text as attribute to the variable
attributes(d.diamonds$colour)

# label is supported while describing data
Desc(d.diamonds$colour)

# The label can be deleted by setting it to NULL
Label(d.diamonds$colour) <- NULL

# Labelling the columns of a data.frame is best done with a loop
# (all so far seen *apply approches lead to more complicated code...)
lbl <- RndWord(16, 7)
for(i in seq_along(lbl))
  Label(d.pizza[, i]) <- lbl[i]

Str(d.pizza)
```

---

**Lambda**

*Goodman Kruskal Lambda*

**Description**

Calculate symmetric and asymmetric Goodman Kruskal lambda and their confidence intervals. Lambda is a measure of proportional reduction in error in cross tabulation analysis. For any sample with a nominal independent variable and dependent variable (or ones that can be treated nominally), it indicates the extent to which the modal categories and frequencies for each value of the independent variable differ from the overall modal category and frequency, i.e. for all values of the independent variable together.

**Usage**

```r
Lambda(x, y = NULL, direction = c("symmetric", "row", "column"), conf.level = NA, ...)
```
Lambda

Arguments

- **x**: a numeric vector, a matrix or a table.
- **y**: NULL (default) or a vector with compatible dimensions to x. If y is provided, table(x,y,...) is calculated.
- **direction**: type of lambda. Can be one out of "symmetric" (default), "row", "column" (abbreviations are allowed). If direction is set to "row" then Lambda(R|C) (column dependent) will be reported. See details.
- **conf.level**: confidence level for the returned confidence interval, restricted to lie between 0 and 1.
- **...**: further arguments are passed to the function `table`, allowing i.e. to set useNA = c("no","ifany","always").

Details

Asymmetric lambda is interpreted as the probable improvement in predicting the column variable Y given knowledge of the row variable X.

The nondirectional lambda is the average of the two asymmetric lambdas, Lambda(C|R) and Lambda(R|C). Lambda (asymmetric and symmetric) has a scale ranging from 0 to 1.

Data can be passed to the function either as matrix or data.frame in x, or as two numeric vectors in x and y. In the latter case `table(x,y,...)` is calculated. Thus NAs are handled the same way as `table` does. Note that tables are by default calculated without NAs (which breaks the package’s law to in general not omit NAs silently). The specific argument useNA can be passed via the ... argument.

`PairApply` can be used to calculate pairwise lambdas.

Value

if no confidence intervals are requested: the estimate as numeric value

else a named numeric vector with 3 elements

- **lambda**: estimate
- **lwr.ci**: lower confidence interval
- **upr.ci**: upper confidence interval

Author(s)

Andri Signorell <andri@signorell.net> based on code from Antti Arppe <antti.arppe@helsinki.fi>, Nanina Anderegg (confidence interval symmetric lambda)

Examples

# example from Goodman Kruskal (1954)
m <- as.table(cbind(c(1768,946,115), c(807,1387,438), c(189,746,288), c(47,53,16)))
dimnames(m) <- list(paste("A", 1:3), paste("B", 1:4))
m

# direction default is "symmetric"
Lambda(m)
Lambda(m, conf.level=0.95)

Lambda(m, direction="row")
Lambda(m, direction="column")
plot(x, col = 1, lwd = 2, lty = 1, main = "Lorenz curve",
     xlab = "p", ylab = "L(p)", ...)

## S3 method for class 'Lc'
lines(x, general = FALSE, lwd = 2, conf.level = NA, args.cband = NULL, ...)

## S3 method for class 'Lc'
predict(object, newdata, conf.level=NA, general=FALSE, n=1000, ...)

Arguments

- **x**: a vector containing non-negative elements, or a Lc-object for plot and lines.
- **n**: a vector of frequencies, must be same length as x.
- **na.rm**: logical. Should missing values be removed? Defaults to FALSE.
- **general**: logical. If TRUE the empirical Lorenz curve will be plotted.
- **col**: color of the curve
- **lwd**: the linewidth of the curve
- **lty**: the linetype of the curve
- **type**: type of the plot, default is line ("l").
- **xlab, ylab**: label of the x-, resp. y-axis.
- **pch**: the point character (default is NA, meaning no points will be drawn)
- **main**: main title of the plot.
- **las**: las of the axis.
- **formula**: a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
- **conf.level**: confidence level for the bootstrap confidence interval. Set this to NA, if no confidence band should be plotted. Default is NA.
- **args.cband**: list of arguments for the confidence band, such as color or border (see DrawBand).
- **object**: object of class inheriting from "Lc"
- **newdata**: an optional vector of percentages p for which to predict. If omitted, the original values of the object are used.
- **...**: further argument to be passed to methods.
Details

\(Lc(x)\) computes the empirical ordinary Lorenz curve of \(x\) as well as the generalized Lorenz curve (= ordinary Lorenz curve \(*\) mean(\(x\))). The result can be interpreted like this: \(p\)*100 percent have \(L(p)\)*100 percent of \(x\).

If \(n\) is changed to anything but the default \(x\) is interpreted as a vector of class means and \(n\) as a vector of class frequencies: in this case \(Lc\) will compute the minimal Lorenz curve (= no inequality within each group).

Value

A list of class "Lc" with the following components:

- \(p\) vector of percentages
- \(L\) vector with values of the ordinary Lorenz curve
- \(L_{\text{general}}\) vector with values of the generalized Lorenz curve
- \(x\) the original \(x\) values (needed for computing confidence intervals)
- \(n\) the original \(n\) values

Note

These functions were previously published as \(Lc()\) in the \texttt{ineq}\package\ and have been integrated here without logical changes.

LehmacherTest

Lehmacher's Test for Marginal Homogeneity

Description

Performs Lehmacher's chi-squared test for marginal homogeneity in a symmetric two-dimensional contingency table.

Usage

LehmacherTest(x, y = NULL)

## S3 method for class 'mtest'
print(x, digits = 4L, ...)

Arguments

x

either a two-dimensional contingency table in matrix form, or a factor object.
y

a factor object; ignored if x is a matrix.
digits

a non-null value for digits specifies the minimum number of significant digits to be printed in values. See details in \texttt{print.default}.

... further arguments to be passed to or from other methods. They are ignored in this function.

Details

The null is that the probabilities of being classified into cells $[i,j]$ and $[j,i]$ are the same.

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.
Value

A list with class "mtest" containing the following components:

- **statistic**: a vector with the value of the test statistics.
- **parameter**: the degrees of freedom, which is always 1 in LehmacherTest.
- **p.value**: a vector with the p-values of the single tests.
- **p.value.corr**: a vector with the "hochberg" adjusted p-values of the single tests. (See `p.adjust`)
- **method**: a character string indicating what type of test was performed.
- **data.name**: a character string giving the name of the data.

**LeveneTest**

*Levene’s Test for Homogeneity of Variance*

Description

Computes Levene’s test for homogeneity of variance across groups.

Usage

```r
LeveneTest(y, ...)

# S3 method for class 'formula'
LeveneTest(formula, data, ...)

# S3 method for class 'lm'
LeveneTest(y, ...)

# Default S3 method:
LeveneTest(y, group, center=median, ...)
```
Arguments

response variable for the default method, or a lm or formula object. If \( y \) is a linear-model object or a formula, the variables on the right-hand-side of the model must all be factors and must be completely crossed.

factor defining groups.

The name of a function to compute the center of each group; mean gives the original Levene’s test; the default, median, provides a more robust test (Brown-Forsythe-Test).

a formula of the form \( lhs \sim rhs \) where \( lhs \) gives the data values and \( rhs \) the corresponding groups.

an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula \( formula \). By default the variables are taken from environment(\( formula \)).

arguments to be passed down, e.g., data for the formula and lm methods; can also be used to pass arguments to the function given by center (e.g., center=mean and trim=0.1 specify the 10% trimmed mean).

returns an object meant to be printed showing the results of the test.

This function was previously published as leveneTest() in the library(car) and has been integrated here without logical changes.

John Fox <jfox@mcmaster.ca>; original generic version contributed by Derek Ogle adapted from a response posted by Brian Ripley to the r-help email list.

**Lilliefors (Kolmogorov-Smirnov) Test for Normality**

**Description**

Performs the Lilliefors (Kolmogorov-Smirnov) test for the composite hypothesis of normality, see e.g. Thode (2002, Sec. 5.1.1).

**Usage**

LillieTest(x)

**Arguments**

- **x**: a numeric vector of data values, the number of which must be greater than 4. Missing values are allowed.
Details

The Lilliefors (Kolmogorov-Smirnov) test is an EDF omnibus test for the composite hypothesis of normality. The test statistic is the maximal absolute difference between empirical and hypothetical cumulative distribution function. It may be computed as

$$D = \max \big\{ D^+, D^- \big\}$$

where

$$D^+ = \max_{i=1, \ldots, n} \{ i/n - p(i) \},$$

$$D^- = \max_{i=1, \ldots, n} \{ p(i) - (i-1)/n \},$$

and $p(i) = \Phi([x(i) - \overline{x}] / s)$. Here, $\Phi$ is the cumulative distribution function of the standard normal distribution, and $\overline{x}$ and $s$ are mean and standard deviation of the data values. The p-value is computed from the Dallal-Wilkinson (1986) formula, which is claimed to be only reliable when the p-value is smaller than 0.1. If the Dallal-Wilkinson p-value turns out to be greater than 0.1, then the p-value is computed from the distribution of the modified statistic $Z = D(\sqrt{n} - 0.01 + 0.85/\sqrt{n})$, see Stephens (1974), the actual p-value formula being obtained by a simulation and approximation process.

Value

A list of class htest, containing the following components:

- statistic: the value of the Lilliefors (Kolmogorov-Smirnov) statistic.
- p.value: the p-value for the test.
- method: the character string “Lilliefors (Kolmogorov-Smirnov) normality test”.
- data.name: a character string giving the name(s) of the data.

Note

The Lilliefors (Kolmogorov-Smirnov) test is the most famous EDF omnibus test for normality. Compared to the Anderson-Darling test and the Cramer-von Mises test it is known to perform worse. Although the test statistic obtained from LillieTest(x) is the same as that obtained from ks.test(x,"pnorm",mean(x),sd(x)), it is not correct to use the p-value from the latter for the composite hypothesis of normality (mean and variance unknown), since the distribution of the test statistic is different when the parameters are estimated.

The function call LillieTest(x) essentially produces the same result as the S-PLUS function call ks.gof(x) with the distinction that the p-value is not set to 0.5 when the Dallal-Wilkinson approximation yields a p-value greater than 0.1. (Actually, the alternative p-value approximation is provided for the complete range of test statistic values, but is only used when the Dallal-Wilkinson approximation fails.)

LillieTest(runif(100, min = 2, max = 4))

lines.lm  Add a Linear Regression Line

Description

Add a linear regression line to an existing plot. The function first calculates the prediction of a lm object for a reasonable amount of points, then adds the line to the plot and inserts a polygon with the confidence and, if required, the prediction intervals. In addition to abline the function will also display polynomial models.

Usage

## S3 method for class 'lm'
lines(x, col = Pal()[1], lwd = 2, lty = "solid",
    type = "l", n = 100, conf.level = 0.95, args.cband = NULL,
    pred.level = NA, args.pband = NULL, ...)

Arguments

x  linear model object as result from lm(y~x).
col  linecolor of the line. Default is the color returned by Pal()[1].
lwd  line width of the line.
lty  line type of the line.
type  character indicating the type of plotting; actually any of the types as in plot.default. Type of plot, defaults to "l".
n  number of points used for plotting the fit.
conf.level  confidence level for the confidence interval. Set this to NA, if no confidence band should be plotted. Default is 0.95.
args.cband  list of arguments for the confidence band, such as color or border (see DrawBand).
pred.level  confidence level for the prediction interval. Set this to NA, if no prediction band should be plotted. Default is 0.95.
args.pband  list of arguments for the prediction band, such as color or border (see DrawBand).
...  further arguments are not used specifically.
Details

It’s sometimes illuminating to plot a regression line with its prediction, resp. confidence intervals over an existing scatterplot. This only makes sense, if just a simple linear model explaining a target variable by (a function of) one single predictor is to be visualized.

Value

nothing

lines(lm(hp ~ wt, mtcars), col="steelblue")

# add the prediction intervals in different color
plot(hp ~ wt, mtcars)
r.lm <- lm(hp ~ wt, mtcars)
lines(r.lm, col="red", pred.level=0.95, args.band=list(col=SetAlpha("grey",0.3)) )

# works with transformations too
plot(dist ~ speed, cars)
lines(lm(dist ~ poly(speed, degree=2), cars), col=hred)

Add a Loess or a Spline Smoother

Description

Add a loess smoother to an existing plot. The function first calculates the prediction of a loess object for a reasonable amount of points, then adds the line to the plot and inserts a polygon with the confidence intervals.

Usage

## S3 method for class 'loess'
lines(x, col = Pal()[1], lwd = 2, lty = "solid",
     type = "l", n = 100, conf.level = 0.95, args.band = NULL, ...)

lines.loess
## S3 method for class 'smooth.spline'
lines(x, col = Pal()[1], lwd = 2, lty = "solid",
    type = "l", conf.level = 0.95, args.band = NULL, ...)

## S3 method for class 'SmoothSpline'
lines(x, col = Pal()[1], lwd = 2, lty = "solid",
    type = "l", conf.level = 0.95, args.band = NULL, ...)

### Arguments

- **x**: the loess or `smooth.spline` object to be plotted.
- **col**: linecolor of the smoother. Default is `DescTools`'s `col1`.
- **lwd**: line width of the smoother.
- **lty**: line type of the smoother.
- **type**: type of plot, defaults to "l".
- **n**: number of points used for plotting the fit.
- **conf.level**: confidence level for the confidence interval. Set this to NA, if no confidence band should be plotted. Default is 0.95.
- **args.band**: list of arguments for the confidence band, such as color or border (see `DrawBand`).
- **...**: further arguments are passed to the smoother (`loess()` or `SmoothSpline()`).

### Note

Loess can result in heavy computational load if there are many points!

y <- rnorm(100)
plot(x, y)
lines(loess(y~x))

plot(temperature ~ delivery_min, data=d.pizza)
lines(loess(temperature ~ delivery_min, data=d.pizza))

plot(temperature ~ delivery_min, data=d.pizza)
lines(loess(temperature ~ delivery_min, data=d.pizza), conf.level = 0.99,
```
args.band = list(col=SetAlpha("red", 0.4), border="black")

# the default values from scatter.smooth
lines(loess(temperature ~ delivery_min, data=d.pizza,
    span=2/3, degree=1, family="symmetric"), col="red")

---

**LineToUser**

*Convert Line Coordinates To User Coordinates*

### Description

Functions like `mtext` or `axis` use the `line` argument to set the distance from plot. Sometimes it’s useful to have the distance in user coordinates. `LineToUser()` does this nontrivial conversion.

### Usage

`LineToUser(line, side)`

### Arguments

- **line**: the number of lines
- **side**: the side of the plot

### Details

For the `LineToUser` function to work, there must be an open plot.

### Value

the user coordinates for the given lines

### Author(s)

Andri Signorell <andri@signorell.net>

### See Also

`mtext`

### Examples

```r
plot(1:10)
LineToUser(line=2, side=4)
```
LinScale

Linear Scaling

Description

This will scale the numeric vector \( x \) linearly from an old scale between \( \text{low} \) and \( \text{high} \) to a new one between \( \text{newlow} \) and \( \text{newhigh} \).

Usage

\[
\text{LinScale}(x, \text{low} = \text{NULL}, \text{high} = \text{NULL}, \text{newlow} = 0, \text{newhigh} = 1)
\]

Arguments

\( x \)

a numeric matrix(like object).

\( \text{low} \)

numeric. The minimum value of the scale, defaults to \( \text{min}(x) \). This is calculated columnwise by default; defined \( \text{low} \) or \( \text{high} \) arguments will be recycled if necessary.

\( \text{high} \)

numeric. The maximum value of the scale, defaults to \( \text{max}(x) \). This is calculated columnwise by default; when a maxval is entered, it will be recycled.

\( \text{newlow} \)

numeric. The minimum value of the new scale, defaults to 0, resulting in a 0-1 scale for \( x \). \( \text{newlow} \) is recycled if necessary.

\( \text{newhigh} \)

numeric. The maximum value of the scale, defaults to 1. \( \text{newhigh} \) is recycled if necessary.

Details

Hmm, hardly worth coding...

Value

The centered and scaled matrix. The numeric centering and scalings used (if any) are returned as attributes "scaled:center" and "scaled:scale"

Author(s)

Andri Signorell <andri@signorell.net>

See Also

scale, RobScale, sweep
Examples

# transform the temperature from Celsius to Fahrenheit
LinScale(d.pizza[1:20, "temperature"], 0, 100, -17.8, 37.8)

# and the price from Dollar to Euro
LinScale(d.pizza[1:20, "price"], 0, 1, 0, 0.76)

# together
LinScale(d.pizza[1:20, c("temperature", "price")],
0, c(100, 1), c(-17.8, 0), c(37.8, 0.76))

## Not run:
par(mfrow=c(3,1), mar=c(0,5,0,3), oma=c(5,0,5,0))
plot(LinScale(d.frm[,1]), ylim=c(-2,2), xaxt="n", ylab="LinScale")
plot(RobScale(d.frm[,1]), ylim=c(-2,2), xaxt="n", ylab="RobScale")
plot(scale(d.frm[,1]), ylim=c(-2,2), ylab="scale")
title("Compare scales", outer = TRUE)

## End(Not run)
**Description**

In longitudinal studies it's common that individuals drop out before all responses can be obtained. Measurements obtained before the individual dropped out can be used to impute the unknown measurement(s). The last observation carried forward method is one way to impute values for the missing observations. For the last observation carried forward (LOCF) approach the missing values are replaced by the last observed value of that variable for each individual regardless of when it occurred.

LOCF() replaces NAs with the most recent non-NA prior to it.

**Usage**

```r
LOCF(x)
```

## Default S3 method:
LOCF(x)

## S3 method for class 'data.frame'
LOCF(x)

## S3 method for class 'matrix'
LOCF(x)

**Arguments**

- `x` a vector, a data.frame or a matrix containing NAs.

**Details**

The function will replace all NAs found in a vector with the last earlier value not being NA. In data.frames each column will be treated as described.

It should be noted, that the last observation carried forward approach may result in biased estimates and may underestimate the variability.
Local Outlier Factor

Description

A function that finds the local outlier factor (Breunig et al., 2000) of the matrix "data" using k neighbours. The local outlier factor (LOF) is a measure of outlyingness that is calculated for each observation. The user decides whether or not an observation will be considered an outlier based on this measure. The LOF takes into consideration the density of the neighborhood around the observation to determine its outlyingness.

Usage

LOF(data, k)

Arguments

data The data set to be explored
k The kth-distance to be used to calculate the LOF's.

Details

The LOFs are calculated over a range of values, and the max local outlier factor is determined over this range.

Value

lof A vector with the local outlier factor of each observation
Logit

Note
This function was originally published in the library dprep.

Author(s)
Caroline Rodriguez

References

Examples
  # Detecting the top 10 outliers using the LOF algorithm
  (iris.lof <- LOF(iris[, -5], 10))

Logit

Generalized Logit and Inverse Logit Function

Description
Compute generalized logit and generalized inverse logit functions.

Usage
Logit(x, min = 0, max = 1)
LogitInv(x, min = 0, max = 1)

Arguments
x       value(s) to be transformed
min     lower end of logit interval
max     upper end of logit interval

Details
The generalized logit function takes values on [min, max] and transforms them to span \([-\infty, \infty]\). It is defined as:

\[ y = \log \left( \frac{p}{1 - p} \right) \quad \text{where} \quad p = \frac{x - \text{min}}{\text{max} - \text{min}} \]

The generalized inverse logit function provides the inverse transformation:

\[ x = p' \cdot (\text{max} - \text{min}) + \text{min} \quad \text{where} \quad p' = \frac{\exp(y)}{1 + \exp(y)} \]
Value

Transformed value(s).

Author(s)

Gregory R. Warnes <greg@warnes.net>

See Also

logit

Examples

```r
x <- seq(0,10, by=0.25)
x <- Logit(x, min=0, max=10)
cbind(x,xt)

y <- LogitInv(xt, min=0, max=10)
cbind(x, xt, y)
```

Description

Transforms the data by a log transformation, modifying small and zero observations such that the transformation is linear for \( x \leq \text{threshold} \) and logarithmic for \( x > \text{threshold} \). So the transformation yields finite values and is continuously differentiable.

Usage

```r
LogSt(x, base = 10, calib = x, threshold = NULL, mult = 1)
LogStInv(x, base = NULL, threshold = NULL)
```

Arguments

- **x**: a vector or matrix of data, which is to be transformed
- **base**: a positive or complex number: the base with respect to which logarithms are computed. Defaults to 10. Use=exp(1) for natural log.
- **calib**: a vector or matrix of data used to calibrate the transformation(s), i.e., to determine the constant \( c \) needed
- **threshold**: constant \( c \) that determines the transformation. The inverse function LogStInv will look for an attribute named "threshold" if the argument is set to NULL.
- **mult**: a tuning constant affecting the transformation of small values, see Details.
Details

In order to avoid $\log(x) = -\infty$ for $x = 0$ in log-transformations there’s often a constant added to the variable before taking the $\log$. This is not always a pleasable strategy. The function LogSt handles this problem based on the following ideas:

- The modification should only affect the values for "small" arguments.
- What "small" is should be determined in connection with the non-zero values of the original variable, since it should behave well (be equivariant) with respect to a change in the "unit of measurement".
- The function must remain monotone, and it should remain (weakly) convex.

These criteria are implemented here as follows: The shape is determined by a threshold $c$ at which - coming from above - the log function switches to a linear function with the same slope at this point. This is obtained by

$$g(x) = \begin{cases} 
\log_{10}(x) & \text{for } x \geq c \\
\log_{10}(c) - \frac{c-x}{c\log(10)} & \text{for } x < c
\end{cases}$$

Small values are determined by the threshold $c$. If not given by the argument threshold, it is determined by the quartiles $q_1$ and $q_3$ of the non-zero data as those smaller than $c = \frac{q_1 + r \cdot q_3}{2}$ where $r$ can be set by the argument mult. The rationale is, that, for lognormal data, this constant identifies 2 percent of the data as small. Beyond this limit, the transformation continues linear with the derivative of the log curve at this point.

Another idea for choosing the threshold $c$ was: median(x) / (median(x)/quantile(x, 0.25))^2.9)

The function chooses $\log_{10}$ rather than natural logs by default because they can be backtransformed relatively easily in mind.

A generalized log (see: Rocke 2003) can be calculated in order to stabilize the variance as:

```r
function (x, a) {
  return(log((x + sqrt(x^2 + a^2)) / 2))
}
```

Value

the transformed data. The value $c$ used for the transformation and needed for inverse transformation is returned as `attr(.,”threshold”)` and the used base as `attr(.,”base”)`.

MAD

Median Absolute Deviation

Description

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

Usage

MAD(x, weights = NULL, center = Median, constant = 1.4826, na.rm = FALSE, low = FALSE, high = FALSE)

Arguments

x
weights
center
constant
na.rm
low
high

a numeric vector.
a numerical vector of weights the same length as x giving the weights to use for elements of x.
Optionally, the centre: defaults to the median.
scale factor. (Default 1.4826)
if TRUE then NA values are stripped from x before computation takes place.
if TRUE, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one.
if TRUE, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.
Details

The actual value calculated is \( \text{constant} \times c\text{Median}(\text{abs}(x - \text{center})) \) with the default value of \( \text{center} \) being \( \text{median}(x) \), and \( c\text{Median} \) being the usual, the ‘low’ or ‘high’ median, see the arguments description for \( \text{low} \) and \( \text{high} \) above.

The default constant = 1.4826 (approximately \( 1/\Phi^{-1}(\frac{3}{4}) = 1/qnorm(3/4) \)) ensures consistency, i.e.,

\[
E[\text{mad}(X_1, \ldots, X_n)] = \sigma
\]

for \( X_i \) distributed as \( N(\mu, \sigma^2) \) and large \( n \).

If \( \text{na.rm} \) is TRUE then NA values are stripped from \( x \) before computation takes place. If this is not done then an NA value in \( x \) will cause \( \text{MAD} \) to return NA.

See Also

\( \text{IQR} \) which is simpler but less robust, \( \text{median}, \text{var} \).

Examples

\[
\begin{align*}
\text{MAD}(c(1:9)) \\
\text{print(MAD}(c(1:9), \text{constant} = 1)) == \\
& \quad \text{MAD}(c(1:8, 100), \text{constant} = 1) \quad # = 2 \ ; \ \text{TRUE} \\
x & \leftarrow c(1,2,3,5,7,8) \\
\text{sort(abs}(x - \text{median}(x)) \text{)} \\
c(MAD(x, \text{constant} = 1), \\
& \quad \text{MAD}(x, \text{constant} = 1, \text{low} = \text{TRUE}), \\
& \quad \text{MAD}(x, \text{constant} = 1, \text{high} = \text{TRUE}))
\end{align*}
\]

Mar and Mgp

Set Plot Margins and Distances

Description

Plot margins are normally set by \texttt{par("mar")}. However one is forced to always define all margins, even if just one should be altered. The convenience function \texttt{Mar()} allows to set one single margin (or several) while leaving the others unchanged.

\texttt{Mgp()} does the same for the distances of axis title, labels and line.

Usage

\[
\begin{align*}
\text{Mar}(& \text{bottom} = \text{NULL}, \text{left} = \text{NULL}, \text{top} = \text{NULL}, \text{right} = \text{NULL}, \text{outer} = \text{FALSE}, \\
& \quad \text{reset} = \text{FALSE}) \\
\text{Mgp}(& \text{title} = \text{NULL}, \text{labels} = \text{NULL}, \text{line} = \text{NULL}, \text{reset} = \text{FALSE})
\end{align*}
\]
Arguments

- **bottom**: the bottom margin, if set to NULL the current value will be maintained.
- **left**: the left margin, if set to NULL the current value will be maintained.
- **top**: the top margin, if set to NULL the current value will be maintained.
- **right**: the right margin, if set to NULL the current value will be maintained.
- **outer**: logical, defining if inner margins (par("mar")) or the outer margins (par("oma")) should be set. Default is FALSE, meaning that the inner margins will be concerned.
- **reset**: if set to TRUE the margins are reset to the defaults (respecting outer). Other arguments are ignored.
- **title**: margin line for the axis title (default 3)
- **labels**: margin line for the axis labels (default 1)
- **line**: margin line for the axis line (default 0)

Details

Running Mar() without any arguments will return the current settings, either par("mar"), when outer is set to FALSE or par("oma") for outer = TRUE.

Author(s)

Andri Signorell <andri@signorell.net>

       ylab="driver", col=Pal("Helsana"))

matpow

Matrix Power

Description

Compute the k-th power of a matrix. Whereas x^k computes element wise powers, x %^% k corresponds to k - 1 matrix multiplications, x %*% x %*% ... %*% x.

Usage

x %^% k
Arguments

- `x`: a square matrix.
- `k`: an integer, \( k \geq 0 \).

Details

Argument \( k \) is coerced to integer using `as.integer`.

The algorithm uses \( O(\log_2(k)) \) matrix multiplications.

Value

A matrix of the same dimension as \( x \).

Note

If you think you need \( x^k \) for \( k < 0 \), then consider instead `solve(x %*% (-k))`.

Author(s)

Based on an R-help posting of Vicente Canto Casasola, and Vincent Goulet's C implementation in `actuar`.

See Also

`%*%` for matrix multiplication.

Examples

```r
A <- cbind(1, 2 * diag(3)[,-1])
A
A %*% 2
stopifnot(identical(A, A %*% 1),
    A %*% 2 == A %*% A)
```

---

### Mean

(Weighted) Arithmetic Mean

Description

Generic function for the (trimmed) arithmetic mean, possibly with given weights.
Mean

Usage

Mean(x, ...)

## S3 method for class 'Freq'
Mean(x, breaks, ...)

## Default S3 method:
Mean(x, weights = NULL, trim = 0, na.rm = FALSE, ...)

Arguments

x
An R object. Currently there are methods for numeric/logical vectors and date, date-time and time interval objects. Complex vectors are allowed for \( \text{trim} = 0 \), only.

weights
a numerical vector of weights the same length as \( x \) giving the weights to use for elements of \( x \).

trim
the fraction (0 to 0.5) of observations to be trimmed from each end of \( x \) before the mean is computed. Values of trim outside that range are taken as the nearest endpoint.

breaks
breaks for calculating the mean for classified data as composed by \( \text{Freq} \).

na.rm
a logical value indicating whether \( \text{NA} \) values should be stripped before the computation proceeds.

...
further arguments passed to or from other methods.

Value

If \( \text{trim} \) is zero (the default), the arithmetic mean of the values in \( x \) is computed, as a numeric or complex vector of length one. If \( x \) is not logical (coerced to numeric), numeric (including integer) or complex, \( \text{NA} \_\_\text{real} \_ \) is returned, with a warning.

If \( \text{trim} \) is non-zero, a symmetrically trimmed mean is computed with a fraction of \( \text{trim} \) observations deleted from each end before the mean is computed.

\( \text{trim} \) and \( \text{weights} \) can’t be used together at the same time.

References

See Also

\text{weighted.mean}, \text{mean.POSIXct}, \text{colMeans} for row and column means.

Examples

\( x \leftarrow \text{c}(0:10, 50) \)
\( \text{xm} \leftarrow \text{Mean}(x) \)
\( \text{c(xm, Mean(x, trim = 0.10))} \)
MeanAD

Mean Absolute Deviation From a Center Point

Description

Calculates the mean absolute deviation from a center point, typically the sample mean or the median.

Usage

MeanAD(x, weights = NULL, center = Mean, na.rm = FALSE)

Arguments

- **x**: a vector containing the observations.
- **weights**: a numerical vector of weights the same length as x giving the weights to use for elements of x.
- **center**: a single numerical value or the name of a function to be used as center. Can as well be a self defined function. Default is Mean().
- **na.rm**: a logical value indicating whether or not missing values should be removed. Defaults to FALSE.

Details

The MeanAD function calculates the mean absolute deviation from the mean value (or from another supplied center point) of x, after having removed NA values (if requested):

\[
\frac{1}{n} \cdot \sum_{i=1}^{n} |x_i - c| \quad \text{where } c = mean(x) \text{ or } c = med(x)
\]

The function supports the use of weights. The default function for the center value Mean() has a weights arguments, too. If a user defined function is used it must be assured that it has a weights argument.

Value

Numeric value.

Author(s)

Andri Signorell <andri@signorell.net> following an idea of Daniel Navarro (aad in the lsr package)

See Also

mad
Examples

```r
x <- runif(100)
MeanAD(x)

speed <- c(58, 88, 40, 60, 72, 66, 80, 48, NA)
MeanAD(speed)
MeanAD(speed, na.rm = TRUE)

# using the median as centerpoint
x <- c(2,3,5,3,1,15,23)
MeanAD(x, center = mean)
MeanAD(x, center = median)

# define a fixed center
MeanAD(x, center = 4)

# use of weights
MeanAD(x=0:6, weights=c(21,46,54,40,24,10,5))
```

---

### MeanCI

**Confidence Interval for the Mean**

**Description**

Collection of several approaches to determine confidence intervals for the mean. Both, the classical way and bootstrap intervals are implemented for both, normal and trimmed means.

**Usage**

```r
MeanCI(x, sd = NULL, trim = 0, method = c("classic", "boot"),
    conf.level = 0.95, sides = c("two.sided", "left", "right"),
    na.rm = FALSE, ...)
```

**Arguments**

- `x`: a (non-empty) numeric vector of data values.
- `sd`: the standard deviation of `x`. If provided it's interpreted as `sd` of the population and the normal quantiles will be used for constructing the confidence intervals. If left to `NULL` (default) the sample `sd(x)` will be calculated and used in combination with the `t`-distribution.
- `trim`: the fraction (0 to 0.5) of observations to be trimmed from each end of `x` before the mean is computed. Values of `trim` outside that range are taken as the nearest endpoint.
- `method`: A vector of character strings representing the type of intervals required. The value should be any subset of the values "classic", "boot". See `boot.ci`.
conf.level  confidence level of the interval.
sides  a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.
na.rm  a logical value indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
...
  further arguments are passed to the boot function. Supported arguments are type ("norm", "basic", "stud", "perc", "bca"), parallel and the number of bootstrap replicates R. If not defined those will be set to their defaults, being "basic" for type, option "boot.parallel" (and if that is not set, "no") for parallel and 999 for R.

Details

The confidence intervals for the trimmed means use winsorized variances as described in the references.
Use do.call, rbind and lapply for getting a matrix with estimates and confidence intervals for more than 1 column. (See examples!)

Value

a numeric vector with 3 elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean</td>
<td>mean</td>
</tr>
<tr>
<td>lwr.ci</td>
<td>lower bound of the confidence interval</td>
</tr>
<tr>
<td>upr.ci</td>
<td>upper bound of the confidence interval</td>
</tr>
</tbody>
</table>

MeanDiffCI

Confidence Interval For Difference of Means

Description

Calculates the confidence interval for the difference of two means either the classical way or with
the bootstrap approach.

Usage

MeanDiffCI(x, ...)  

## Default S3 method:
MeanDiffCI(x, y, method = c("classic", "norm", "basic", "stud", "perc", "bca"),
  conf.level = 0.95, sides = c("two.sided", "left", "right"), paired = FALSE,
  na.rm = FALSE, R = 999, ...)  

## S3 method for class 'formula'
MeanDiffCI(formula, data, subset, na.action, ...)

Arguments

x a (non-empty) numeric vector of data values.
y a (non-empty) numeric vector of data values.
method a vector of character strings representing the type of intervals required. The
value should be any subset of the values "classic", "norm", "basic", "stud",  
"perc", "bca". See boot.ci.
MeanDiffCI

conf.level  confidence level of the interval.
sides       a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.
paired      a logical indicating whether you want confidence intervals for a paired design. Defaults to FALSE.
na.rm       logical. Should missing values be removed? Defaults to FALSE.
R           the number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case R would be a vector of integers where each component gives the number of resamples from each of the rows of weights. See boot.
formula     a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data        an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset      an optional vector specifying a subset of observations to be used.
na.action   a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
...         further argument to be passed to or from methods.

Details

This function collects code from two sources. The classical confidence interval is calculated by means of t.test. The bootstrap intervals are strongly based on the example in boot.

Value

a numeric vector with 3 elements:

meanDiff    the difference: mean(x) - mean(y)
lwr.ci      lower bound of the confidence interval
upr.ci      upper bound of the confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

### MeanSE

**Standard Error of Mean**

**Description**

Calculates the standard error of mean.

**Usage**

```r
MeanSE(x, sd = NULL, na.rm = FALSE)
```

**Arguments**

- **x**: a (non-empty) numeric vector of data values.
- **sd**: the standard deviation of `x`. If provided it’s interpreted as `sd` of the population. If left to `NULL` (default) the sample `sd(x)` will be used.
- **na.rm**: logical. Should missing values be removed? Defaults to `FALSE`.

**Details**

MeanSE calculates the standard error of the mean defined as:

\[
\frac{\sigma}{\sqrt{n}}
\]

\(\sigma\) being standard deviation of `x` and \(n\) the length of `x`.

**Value**

the standard error as numeric value.
Measures of Accuracy

Author(s)
Andri Signorell <andri@signorell.net>

See Also
MeanCI

Examples

data(d.pizza)

MeanSE(d.pizza$price, na.rm=TRUE)

# evaluate data.frame
sapply(d.pizza[,1:4], MeanSE, na.rm=TRUE)

Description
Some measures of model accuracy like mean absolute error (MAE), mean absolute percentage error (MAPE), symmetric mean absolute percentage error (SMAPE), mean squared error (MSE) and root mean squared error (RMSE).

Usage
MAE(x, ...)
## Default S3 method:
MAE(x, ref, na.rm = FALSE, ...)
## S3 method for class 'lm'
MAE(x, ...)

MAPE(x, ...)
## Default S3 method:
MAPE(x, ref, na.rm = FALSE, ...)
## S3 method for class 'lm'
MAPE(x, ...)

SMAPE(x, ...)
## Default S3 method:
SMAPE(x, ref, na.rm = FALSE, ...)
## S3 method for class 'lm'
SMAPE(x, ...)

MSE(x, ...)
## Default S3 method:
Measures of Accuracy

\[ \text{MSE}(x, \text{ref}, \text{na.rm} = \text{FALSE}, \ldots) \]

## S3 method for class 'lm'
MSE(x, \ldots)

\[ \text{RMSE}(x, \ldots) \]

## Default S3 method:
RMSE(x, \text{ref}, \text{na.rm} = \text{FALSE}, \ldots)

## S3 method for class 'lm'
RMSE(x, \ldots)

\[ \text{NMAE}(x, \text{ref}, \text{train.y}) \]
\[ \text{NMSE}(x, \text{ref}, \text{train.y}) \]

### Arguments

- **x**: the predicted values of a model or a model-object itself.
- **ref**: the observed true values.
- **train.y**: the observed true values in a train dataset.
- **na.rm**: a logical value indicating whether or not missing values should be removed. Defaults to FALSE.
- **\ldots**: further arguments

### Details

The function will remove NA values first (if requested).

\text{MAE} calculates the mean absolute error:

\[ \frac{1}{n} \cdot \sum_{i=1}^{n} |\text{ref}_i - x_i| \]

\text{MAPE} calculates the mean absolute percentage error:

\[ \frac{1}{n} \cdot \sum_{i=1}^{n} \left| \frac{\text{ref}_i - x_i}{\text{ref}_i} \right| \]

\text{SMAPE} calculates the symmetric mean absolute percentage error:

\[ \frac{1}{n} \cdot \sum_{i=1}^{n} \frac{2 \cdot |\text{ref}_i - x_i|}{|\text{ref}_i| + |x_i|} \]
Measures of Accuracy

MSE calculates mean squared error:

\[
\frac{1}{n} \cdot \sum_{i=1}^{n} (ref_i - x_i)^2
\]

RMSE calculates the root mean squared error:

\[
\sqrt{\frac{1}{n} \cdot \sum_{i=1}^{n} (ref_i - x_i)^2}
\]

Value

the specific numeric value

Author(s)

Andri Signorell <andri@signorell.net>

`lm`, `resid`

Examples

```r
r.lm <- lm(Fertility ~ ., data=swiss)

MAE(r.lm)

# the same as:
MAE(predict(r.lm), swiss$Fertility)

MAPE(r.lm)
MSE(r.lm)
RMSE(r.lm)
```
Skewness and Kurtosis

Description

Skew computes the skewness, Kurt the kurtosis of the values in x.

Usage

```r
Skew(x, weights = NULL, na.rm = FALSE, method = 3, conf.level = NA, ci.type = "bca", R = 1000, ...)
Kurt(x, weights = NULL, na.rm = FALSE, method = 3, conf.level = NA, ci.type = "bca", R = 1000, ...)
```

Arguments

- **x**: a numeric vector. An object which is not a vector is coerced (if possible) by `as.vector`.
- **weights**: a numerical vector of weights the same length as `x` giving the weights to use for elements of `x`.
- **na.rm**: logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
- **method**: integer out of 1, 2 or 3 (default). See Details.
- **conf.level**: confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
- **ci.type**: The type of confidence interval required. The value should be any subset of the values "classic", "norm", "basic", "stud", "perc" or "bca" ("all" which would compute all five types of intervals, is not supported).
- **R**: The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case `R` would be a vector of integers where each component gives the number of resamples from each of the rows of weights.
- **...**: the dots are passed to the function `boot`, when confidence intervals are calculated.

Details

If `na.rm` is TRUE then missing values are removed before computation proceeds.

The methods for calculating the skewness can either be:

- **method = 1**: \( g_1 = m_3 / m_2^{(3/2)} \)
Measures of Shape

method = 2: $G_1 = g_1 \sqrt{n(n-1)} / (n-2)$
method = 3: $b_1 = m_3 / s^3 = g_1 ((n-1)/n)^{(3/2)}$

and the ones for the kurtosis:
method = 1: $g_2 = m_4 / m_2^2 - 3$
method = 2: $G_2 = ((n+1) g_2 + 6) * (n-1) / ((n-2)(n-3))$
method = 3: $b_2 = m_4 / s^4 - 3 = (g_2 + 3) (1 -1/n)^2 - 3$

method = 1 is the typical definition used in many older textbooks.
method = 2 is used in SAS and SPSS.
method = 3 is used in MINITAB and BMDP.

Cramer et al. (1997) mention the asymptotic standard error of the skewness, resp. kurtosis:

$$ASE\text{.skew} = \sqrt{6n(n-1)/((n-2)(n+1)(n+3))}$$
$$ASE\text{.kurt} = \sqrt{(n^2 - 1)/((n-3)(n+5))}$$

to be used for calculating the confidence intervals. This is implemented here with ci.type="classic". However, Joanes and Gill (1998) advise against this approach, pointing out that the normal assumptions would virtually always be violated. They suggest using the bootstrap method. That’s why the default method for the confidence interval type is set to "bca".

This implementation of the two functions is comparably fast, as the expensive sums are coded in C.

Value

If conf.level is set to NA then the result will be

a single numeric value

and if a conf.level is provided, a named numeric vector with 3 elements:

- skew, kurt: the specific estimate, either skewness or kurtosis
- lwr.ci: lower bound of the confidence interval
- upr.ci: upper bound of the confidence interval

Author(s)

Andri Signorell <andri@signorell.net>, David Meyer <david.meyer@r-project.org> (method = 3)

mean, sd, similar code in library(e1071)

Examples

Skew(d.pizza$price, na.rm=TRUE)
Kurt(d.pizza$price, na.rm=TRUE)

# use sapply to calculate skewness for a data.frame
sapply(d.pizza[,c("temperature","price","delivery_min")], Skew, na.rm=TRUE)

# or apply to do that columnwise with a matrix
apply(as.matrix(d.pizza[,c("temperature","price","delivery_min")]), 2, Skew, na.rm=TRUE)

Description

Compute the sample median. The function basically wraps the base R function median() and adds the option to define weights.
For grouped data the median can be estimated by linear interpolation within the class containing the median, which is implemented in the interface for Freq-objects.

Usage

Median(x, ...)

## S3 method for class 'factor'
Median(x, na.rm = FALSE, ...)

## S3 method for class 'Freq'
Median(x, breaks, ...)

## Default S3 method:
Median(x, weights = NULL, na.rm = FALSE, ...)

Arguments

x an object for which a method has been defined, or a numeric vector containing the values whose median is to be computed.
weights a numerical vector of weights the same length as x giving the weights to use for elements of x.
breaks breaks for calculating the mean for classified data as composed by Freq.
n.a.rm a logical value indicating whether NA values should be stripped before the computation proceeds.
... further arguments passed to or from other methods.
Details

This is a generic function for which methods can be written. However, the default method makes use of is.na, sort and mean from package base all of which are generic, and so the default method will work for most classes (e.g., "Date") for which a median is a reasonable concept.

Calculating the median for ordered factors is not implemented in standard R, as it’s not well defined (it is not clear what to do if the median sits between two levels in factors of even length). This function returns the high median and prints a warning if the low median would be different (which is supposed to be a rare event). There’s a vivid discussion between experts going on whether this should be defined or not. We’ll wait for definitive results and enjoy the function’s comfort so far...

Note that there are alternative approaches for calculating weighted median (e.g. matrixstats::weightedMedian).

Value

The default method returns a length-one object of the same type as x, except when x is integer of even length, when the result will be double.

If there are no values or if na.rm = FALSE and there are NA values the result is NA of the same type as x (or more generally the result of x[FALSE][NA]).

---

**MedianCI**

**Confidence Interval for the Median**

**Description**

Calculates the confidence interval for the median.

**Usage**

MedianCI(x, conf.level = 0.95, sides = c("two.sided", "left", "right"),
na.rm = FALSE, method = c("exact", "boot"), R = 999)

**Arguments**

- **x**
  a (non-empty) numeric vector of data values.

- **conf.level**
  confidence level of the interval

- **sides**
  a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.

- **na.rm**
  logical. Should missing values be removed? Defaults to FALSE.

- **method**
  defining the type of interval that should be calculated (one out of "exact", "boot"). Default is "exact". See Details.

- **R**
  The number of bootstrap replicates. Usually this will be a single positive integer. See boot.ci for details.

**Details**

The "exact" method is the way SAS is said to calculate the confidence interval. This is implemented in SignTest and is extracted therefrom. The boot confidence interval type is calculated by means of boot.ci with default type "basic".

Use sapply, resp. apply, to get the confidence intervals from a data.frame or from a matrix.
MHChisqTest

Value

a numeric vector with 3 elements:

- median
- lwr.ci lower bound of the confidence interval
- upr.ci upper bound of the confidence interval

MHChisqTest (Mantel-Haenszel Chi-Square Test)

Description

The Mantel-Haenszel chi-square statistic tests the alternative hypothesis that there is a linear association between the row variable and the column variable. Both variables must lie on an ordinal scale.

Usage

MHChisqTest(x, srow = 1:nrow(x), scol = 1:ncol(x))

Arguments

- x: a frequency table or a matrix.
- srow: scores for the row variable, defaults to 1:nrow.
- scol: scores for the column variable, defaults to 1:ncol.
Details

The statistic is computed as \( Q_{MH} = (n - 1) \cdot r^2 \), where \( r^2 \) is the Pearson correlation between the row variable and the column variable. The Mantel-Haenszel chi-square statistic use the scores specified by srow and scol. Under the null hypothesis of no association, \( Q_{MH} \) has an asymptotic chi-square distribution with one degree of freedom.

Value

A list with class "htest" containing the following components:

- `statistic` the value the Mantel-Haenszel chi-squared test statistic.
- `parameter` the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- `p.value` the p-value for the test.
- `method` a character string indicating the type of test performed.
- `data.name` a character string giving the name(s) of the data.

```
Find the Midpoints of a Numeric Vector

Description

Calculate the midpoints of a sequence of numbers. This is e.g. useful for labelling stacked barplots.

Usage

Midx(x, incl.zero = FALSE, cumulate = FALSE)

Arguments

x  the numeric vector
incl.zero  should zero be appended to x before proceeding? If TRUE the first value will be one half of the first value of x. Default is FALSE.
cumulate  should the result be calculated as cumulative sum? Default is FALSE.

Value

numeric vector with the calculated midpoins

x <- t(apply(tab, 2, Midx, incl.zero=TRUE, cumulate=TRUE))
text(tab, x=x, y=b, col="red")
MixColor

*Compute the Convex Combination of Two Colors*

**Description**

This function can be used to compute the result of color mixing (it assumes additive mixing).

**Usage**

```r
MixColor(col1, col2, amount1 = 0.5)
```

**Arguments**

- `col1`: the first color.
- `col2`: the second color.
- `amount1`: the amount of color1. The amount of color2 results in \(1 - \text{amount1}\).

**Value**

The mixed color as hexstring

# a mix between red and yellow with rates 3:7
MixColor("red", "yellow", 0.3)
```

---

Mode

*Mode, Most Frequent Value(s)*

**Description**

Calculate the mode, the most frequent value, of a numeric or character vector x.

**Usage**

```r
Mode(x, na.rm = FALSE)
```
Mode

Arguments

x a (non-empty) numeric vector of data values.
na.rm logical. Should missing values be removed? Defaults to FALSE.

Details

The mode is usually useful for qualitative data, sometimes still for an integer vector. For numerical vectors, it is not so much the central tendency property of the mode that is interesting as the information about conspicuous accumulation points, which sometimes can indicate data errors. In Desc() it is integrated in the numeric description to draw the analyst’s attention to strikingly high frequencies of a single value as soon as they exceed a certain threshold. (In a numeric vector we would in general rather expect low numbers of tied values, or we should be aware of the process properties that generates them.)

The handling of NA values follows the standards of the package. As soon as a single NA value occurs, NA is returned as result. This approach can sometimes be conservative when calculating the mode. The mode could be determined unambiguously in cases where the number of missing values is small enough that - regardless of what value they have - they cannot alter the sample mode. The modal frequency could then be determined within a lower and upper range. In the example of x=c(1,1,1,1,2,2,NA) we know that the mode of x is 1 regardless of what the true value is for the one missing value; and we know that the modal frequency must be between 4 and 5. However this is not implemented in the function and further considerations in this direction are left to the user here.

The mode is elsewhere often calculated in a crude and wasteful way by tabulating the frequency for all elements of the vector and returning the most frequent one. This function uses a sophisticated data structure in C++ and is limited to determining the most frequent element only. Therefore it is orders of magnitude faster than other implementations, especially for large numeric vectors with large numbers of distinct values.

You might furthermore consider using density(x)$x[which.max(density(x)$y)] for quantitative data or alternatively use hist().

Another interesting idea for a more robust estimation of the mode:

```
peak <- optimize(function(x, model) predict(model, data.frame(x = x)),
            c(min(x), max(x)),
            maximum = TRUE,
            model = y.loess)
```

```
points(peak$maximum, peak$objective, pch=FILLED.CIRCLE <- 19)
```

Value

The most frequent value as number or character, depending of class(x). If there is more than one, all are returned in a vector.

The modal frequency is attached as attribute named “freq”.

MosesTest

Moses Test of Extreme Reactions

Description
Perform Moses test of extreme reactions, which is a distribution-free non-parametric test for the difference between two independent groups in the extremity of scores (in both directions) that the groups contain. Scores from both groups are pooled and converted to ranks, and the test statistic is the span of scores (the range plus 1) in one of the groups chosen arbitrarily. An exact probability is computed for the span and then recomputed after dropping a specified number of extreme scores from each end of its range. The exact one-tailed probability is calculated.

Usage
MosesTest(x, ...)

## Default S3 method:
MosesTest(x, y, extreme = NULL, ...)

## S4 method for signature 'character'
MosesTest(x, y, extreme = NULL, ...)

## S4 method for signature 'character'
MosesTest(x, y, extreme, na.rm = TRUE, ...)
## S3 method for class 'formula'
MosesTest(formula, data, subset, na.action, ...)

### Arguments

- **x**: numeric vector of data values. x will be treated as control group. Non-finite (e.g. infinite or missing) values will be omitted.
- **y**: numeric vector of data values. y will be treated as experiment group. Non-finite (e.g. infinite or missing) values will be omitted.
- **formula**: a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula formula. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **extreme**: integer, defines the number of extreme values to be dropped from the control group before calculating the span. Default (NULL) is the integer part of 0.05 * `length(x)` or 1, whichever is greater. If extreme is too large, it will be cut down to floor(`length(x)-2`)/2.
- **...**: further arguments to be passed to or from methods.

### Details

For two independent samples from a continuous field, this tests whether extreme values are equally likely in both populations or if they are more likely to occur in the population from which the sample with the larger range was drawn.

Note that the ranks are calculated in decreasing mode.

### Value

A list with class “htest” containing the following components:

- **statistic**: the value of the Moses Test statistic.
- **p.value**: the p-value for the test.
- **method**: the character string “Moses Test of Extreme Reactions”.
- **data.name**: a character string giving the name(s) of the data.

MosesTest(x, y)

MoveAvg

Moving Average

Description
Compute a simple moving average (running mean).

Usage
MoveAvg(x, order, align = c("center", "left", "right"),
        endrule = c("NA", "keep", "constant"))

Arguments
x univariate time series.
order order of moving average.
align specifies whether result should be centered (default), left-aligned or right-aligned.
endrule character string indicating how the values at the beginning and the end (of the
data) should be treated.
"keep" keeps the first and last $k_2$ values at both ends, where $k_2$ is the half-
bandwidth $k_2 = k \% / 2$, i.e., $y[j] = x[j]$ for $j \in \{1, \ldots, k_2; n - k_2 + 1, \ldots, n\}$;
"constant" fill the ends with first and last calculated value in output array
(out[1:k2] = out[k2+1])
"NA" the default, leaves the values to NA, as they are returned by filter.
Details

The implementation is using the function `filter` to calculate the moving average.

Value

Returns a vector of the same size and same class as x.

Author(s)

Andri Signorell <andri@signorell.net>

```

---

### MultinomCI

Confidence Intervals for Multinomial Proportions

Description

Confidence intervals for multinomial proportions are often approximated by single binomial confidence intervals, which might in practice often yield satisfying results, but is properly speaking not correct. This function calculates simultaneous confidence intervals for multinomial proportions either according to the methods of Sison and Glaz, Goodman, Wald, Wald with continuity correction or Wilson.

Usage

```r
MultinomCI(x, conf.level = 0.95, sides = c("two.sided", "left", "right"),
method = c("sisonglaz", "cplus1", "goodman", "wald", "waldcc", "wilson"))
```

Arguments

- `x` A vector of positive integers representing the number of occurrences of each class. The total number of samples equals the sum of such elements.
- `conf.level` confidence level, defaults to 0.95.
- `sides` a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.
- `method` character string specifying which method to use; can be one out of "sisonglaz", "cplus1", "goodman", "wald", "waldcc", "wilson". Method can be abbreviated. See details. Defaults to "sisonglaz".
Details

Given a vector of observations with the number of samples falling in each class of a multinomial distribution, builds the simultaneous confidence intervals for the multinomial probabilities according to the method proposed by the mentioned authors. The R code for Sison and Glaz (1995) has been translated from the SAS code written by May and Johnson (2000). Some approaches for the confidence intervals can potentially yield negative results or values beyond 1. These would be reset such as not to exceed the range of [0, 1].

Value

A matrix with 3 columns:

- est: estimate
- lwr.ci: lower bound of the confidence interval
- upr.ci: upper bound of the confidence interval

The number of rows correspond to the dimension of x.

---

**MultMerge**  
*Merge Multiple Data Frames*

**Description**

Merge multiple data frames by row names, or do other versions of database join operations.

**Usage**

MultMerge(..., all.x = TRUE, all.y = TRUE)

**Arguments**

- **...** data frames to be coerced to one.
- **all.x** logical; if TRUE, then extra rows will be added to the output, one for each row in x that has no matching row in y. These rows will have NAs in those columns that are usually filled with values from y. The default is FALSE, so that only rows with data from both x and y are included in the output.
- **all.y** logical; analogous to all.x.

**Value**

A data frame. The rows are sorted according to the appearance of previously unobserved rownames. So the rownames appearing in the first data frame are first, then the rownames in the second data frame, which have no correspondence in the first data frame and so on. The columns are the remaining columns in x1 and then those in x2 and then those in x3. The result has the row names resulting from the merge.

               rownames=c("A", "B", "C", "D", "E", "F"))
x2 <- SetNames(data.frame(v=letters[1:3], ww=11:13),
               rownames=c("B", "C", "D"))
x3 <- SetNames(data.frame(v=letters[12:16], wwww=22:26),
               rownames=c("A", "C", "E", "G", "J"))

MultMerge(x1, x2, x3)
```

NemenyiTest(x, ...)

## Default S3 method:
NemenyiTest(x, g, dist = c("tukey", "chisq"), out.list = TRUE, ...)

## S3 method for class 'formula'
NemenyiTest(formula, data, subset, na.action, ...)

Arguments

- **x**: a numeric vector of data values, or a list of numeric data vectors.
- **g**: a vector or factor object giving the group for the corresponding elements of *x*. Ignored if *x* is a list.
- **dist**: the distribution used for the test. Can be *tukey* (default) or *chisq*.
- **out.list**: logical, defining if the output should be organized in listform.
- **formula**: a formula of the form *lhs ~ rhs* where *lhs* gives the data values and *rhs* the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.
Details

Nemenyi proposed a test based on rank sums and the application of the family-wise error method to control Type I error inflation, if multiple comparisons are done. The Tukey and Kramer approach uses mean rank sums and can be employed for equally as well as unequally sized samples without ties.

Value

A list of class htest, containing the following components:

- statistic: Nemenyi test
- p.value: the p-value for the test
- null.value: is the value of the median specified by the null hypothesis. This equals the input argument mu.
- alternative: a character string describing the alternative hypothesis.
- method: the type of test applied
- data.name: a character string giving the names of the data.

### NPV

Short Selection of Financial Mathematical Functions

**Description**

Calculate the one period returns, the net present value (NPV()), the internal rate of return (IRR()) of a sequence of payments. NPVFixBond() returns the net present value for a fixed-rate bond, YTM() the yield to maturity for a bond.

**Usage**

\[
\text{OPR(K, D = NULL, log = FALSE)}
\]
\[
\text{NPV(i, cf, t = seq(along = cf) - 1)}
\]
\[
\text{IRR(cf, t = seq(along = cf) - 1, interval = c(-1.5, 1.5), ...)}
\]
\[
\text{NPVFixBond(i, Co, RV, n)}
\]
\[
\text{YTM(Co, PP, RV, n)}
\]

**Arguments**

- **i**: the interest rate
- **cf**: numeric vector with the payments
- **t**: periods
- **K**: the capital at time t
- **D**: dividend at time t
- **log**: logical, determining if the simple returns (default) or log returns are to be calculated.
interval a vector containing the end-points of the interval to be searched for the root in the function IRR.

Co coupon payments of a fixed-rate bond

PP purchase price for a fixed-rate bond

RV redemption value

n the term of the bond, total number of periods

... the dots are passed to the UnirootAll function in IRR

Details

The one period returns are calculated as

\[ r_t = \frac{D_t + K_t - K_{t-1}}{K_t - 1} \]

Value

a numeric value

# several IRR solutions
IRR(cf = c(-100, 500, -600))

# no solution
IRR(cf = c(-100, 400, -600))

# negative and huge solution
IRR(cf = c(-100, 1000, -600), interval = c(-1.5, 1000))

Description

Calculates odds ratio by unconditional maximum likelihood estimation (wald), conditional maximum likelihood estimation (mle) or median-unbiased estimation (midp). Confidence intervals are calculated using normal approximation (wald) and exact methods (midp, mle).
Usage

OddsRatio(x, conf.level = NULL, ...)  

## S3 method for class 'glm'
OddsRatio(x, conf.level = NULL, digits = 3, use.profile = TRUE, ...)

## S3 method for class 'multinom'
OddsRatio(x, conf.level = NULL, digits = 3, ...)

## S3 method for class 'zeroinfl'
OddsRatio(x, conf.level = NULL, digits = 3, ...)

## Default S3 method:
OddsRatio(x, conf.level = NULL, y = NULL, method = c("wald", "mle", "midp"),  
           interval = c(0, 1000), ...)

Arguments

x  a vector or a 2 × 2 numeric matrix, resp. table.

y  NULL (default) or a vector with compatible dimensions to x. If y is provided,  
   table(x,y,...) will be calculated.

digits  the number of fixed digits to be used for printing the odds ratios.

method  method for calculating odds ratio and confidence intervals. Can be one out of  
        "wald", "mle", "midp". Default is "wald" (not because it is the best, but because  
        it is the most commonly used.)

conf.level  confidence level. Default is NA for tables and numeric vectors, meaning no con-  
            fidence intervals will be reported. 0.95 is used as default for models.

interval  interval for the function uniroot that finds the odds ratio median-unbiased esti-  
          mate and midp exact confidence interval.

use.profile  logical. Defines if profile approach should be used, which normally is a good  
             choice. Calculating profile can however take ages for large datasets and not be  
             necessary there. So we can fallback to normal confidence intervals.

...  further arguments are passed to the function table, allowing i.e. to set useNA.  
     This refers only to the vector interface.

Details

If a 2 × 2 table is provided the following table structure is preferred:

<table>
<thead>
<tr>
<th></th>
<th>disease=0</th>
<th>disease=1</th>
</tr>
</thead>
<tbody>
<tr>
<td>exposed=0 (ref)</td>
<td>n00</td>
<td>n01</td>
</tr>
<tr>
<td>exposed=1</td>
<td>n10</td>
<td>n11</td>
</tr>
</tbody>
</table>

however, for odds ratios the following table is equivalent:
If the table to be provided to this function is not in the preferred form, the function `Rev()` can be used to "reverse" the table rows, resp. -columns. Reversing columns or rows (but not both) will lead to the inverse of the odds ratio.

In case of zero entries, 0.5 will be added to the table.

**Value**

- a single numeric value if conf.level is set to `NA`
- a numeric vector with 3 elements for estimate, lower and upper confidence interval if conf.level is provided

Distributions of Order Statistics

Description

Density function, distribution function and random generation for a selected Order statistic of a given number of independent variables from a specified distribution.

Usage

dOrder(x, densfun, distnfun, ..., distn, mlen = 1, j = 1,
       largest = TRUE, log = FALSE)
pOrder(q, distnfun, ..., distn, mlen = 1, j = 1, largest = TRUE,
       lower.tail = TRUE)
rOrder(n, quantfun, ..., distn, mlen = 1, j = 1, largest = TRUE)

Arguments

x, q

Number of observations.
densfun, distnfun, quantfun

Density, distribution and quantile function of the specified distribution. The density function must have a log argument (a simple wrapper can always be constructed to achieve this).
Parameters of the specified distribution.

distn A character string, optionally specified as an alternative to densfun, distnfun and quantfun such that the density, distribution and quantile functions are formed upon the addition of the prefixes d, p and q respectively.

mlen The number of independent variables.

j The Order statistic, taken as the jth largest (default) or smallest of mlen, according to the value of largest.

largest Logical; if TRUE (default) use the jth largest Order statistic, otherwise use the jth smallest.

log Logical; if TRUE, the log density is returned.

lower.tail Logical; if TRUE (default) probabilities are \( P[X \leq x] \), otherwise \( P[X > x] \).

Value
dOrder gives the density function, pOrder gives the distribution function and qOrder gives the quantile function of a selected Order statistic from a sample of size mlen, from a specified distribution. rOrder generates random deviates.

ORToRelRisk

Transform Odds Ratio to Relative Risk

Description

Transform a given odds-ratio (OR) to the respective relative risk (RR).

Usage

ORToRelRisk(or, p0)
Arguments

or numeric vector: OR (odds-ratio).
p0 numeric vector: incidence of the outcome of interest in the nonexposed group.

Details

The function transforms a given odds-ratio (OR) to the respective relative risk (RR). It can also be used to transform the limits of confidence intervals.

It uses the formula of Zhang and Yu (1998).

Value

relative risk.

Author(s)

Matthias Kohl <matthias.kohl@stamats.de>

logisticOR

## p0
p0 <- c(0.05, 0.12, 0.32, 0.27, 0.40, 0.40)

## Compute corrected RR
## helper function
ORToRelRisk.mat <- function(or, p0){
  res <- matrix(NA, nrow = nrow(or), ncol = ncol(or))
  ...)
for(i in seq_len(nrow(or)))
  res[i,] <- ORToRelRisk(or[i,], p0[i])
  dimnames(res) <- dimnames(or)
  res
}
RR <- ORToRelRisk.mat(logisticOR, p0)
round(RR, 2)

## Results are not completely identical to Zhang and Yu (1998)
## what probably is caused by the fact that the logistic OR values
## provided in the table are rounded and not true values.

---

**Description**

Return outliers following Tukey’s boxplot definition.

**Usage**

Outlier(x, method = c("boxplot"), value = TRUE, na.rm = FALSE)

**Arguments**

- **x**: a (non-empty) numeric vector of data values.
- **method**: the method to be used. So far only Tukey’s boxplot rule is implemented.
- **value**: logical. If FALSE, a vector containing the (integer) indices of the outliers is returned, and if TRUE (default), a vector containing the matching elements themselves is returned.
- **na.rm**: logical. Should missing values be removed? Defaults to FALSE.

**Details**

Outlier detection is a tricky problem and should be handled with care. We implement only Tukey’s boxplot rule as a rough idea of spotting extreme values.

**Value**

the values of x lying outside the whiskers in a boxplot or the indices of them

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

boxplot
Examples

Outlier(d.pizza$temperature, na.rm=TRUE)

# it's the same as the result from boxplot
sort(d.pizza$temperature[Outlier(d.pizza$temperature, value=FALSE, na.rm=TRUE)])
b <- boxplot(d.pizza$temperature, plot=FALSE)
sort(b$out)

# nice to find the corresponding rows
d.pizza[Outlier(d.pizza$temperature, value=FALSE, na.rm=TRUE), ]

# outliers for the each driver
tapply(d.pizza$temperature, d.pizza$driver, Outlier, na.rm=TRUE)

# the same as:
boxplot(temperature ~ driver, d.pizza)$out

PageTest

Exact Page Test for Ordered Alternatives

Description

Performs a Page test for ordered alternatives using an exact algorithm by Stefan Wellek (1989) with unreplicated blocked data.

Usage

PageTest(y, ...)

## Default S3 method:
PageTest(y, groups, blocks, ...)

## S3 method for class 'formula'
PageTest(formula, data, subset, na.action, ...)

Arguments

y         either a numeric vector of data values, or a data matrix.
groups    a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
blocks    a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
formula   a formula of the form a ~ b | c, where a, b and c give the data values and corresponding groups and blocks, respectively.
**Details**

`PageTest` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the `groups`.

The implemented alternative is, that the location parameter will be monotonically greater along the `groups`,

\[ H_A : \theta_1 \leq \theta_2 \leq \theta_3 \ldots \] (where at least one inequality is strict).

If the other direction is required, the order of the groups has to be reversed.

The Page test for ordered alternatives is slightly more powerful than the Friedman analysis of variance by ranks.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. `NA`'s are not allowed in `groups` or `blocks`; if `y` contains `NA`'s, corresponding blocks are removed.

For small values of `k` (methods) or `N` (data objects), ‘PageTest’ will calculate the exact p-values. For ‘`k,N > 15,Inf`’, a normal approximation is returned. Only one of these values will be returned.

**Value**

A list with class "htest" containing the following components:

- `statistic` the L-statistic with names attribute “L”.
- `p.value` the p-value of the test.
- `method` the character string "Page test for ordered alternatives".
- `data.name` a character string giving the names of the data.

**Note**

Special thanks to Prof. S. Wellek for porting old GAUSS code to R.

**Author(s)**

Stefan Wellek <stefan.wellek@zi-mannheim.de> (exact p-values), Andri Signorell <andri@signorell.net> (interface) (strongly based on R-Core code)

**PairApply**

### Pairwise Calculations

**Description**

Implements a logic to run pairwise calculations on the columns of a data.frame or a matrix.

**Usage**

PairApply(x, FUN = NULL, ..., symmetric = FALSE)

**Arguments**

- **x**: a list, a data.frame or a matrix with columns to be processed pairwise.
- **FUN**: a function to be calculated. It is assumed, that the first 2 arguments denominate x and y.
- **...**: the dots are passed to FUN.
- **symmetric**: logical. Does the function yield the same result for FUN(x, y) and FUN(y, x)? If TRUE just the lower triangular matrix is calculated and transposed. Default is FALSE.
Details

This code is based on the logic of cor() and extended for asymmetric functions.

Value

A matrix with the results of FUN.

Author(s)

Andri Signorell <andri@signorell.net>

# ... and the list interface
lst <- as.list(dfrm)
PairApply(lst, FUN = CramerV, symmetric=TRUE)
 ParseFormula

Parse a Formula and Create a Model Frame

Description

Create a model frame for a formula object, by handling the left hand side the same way the right hand side is handled in model.frame. Especially variables separated by + are interpreted as separate variables.

Usage

ParseFormula(formula, data = parent.frame(), drop = TRUE)

Arguments

formula an object of class "formula" (or one that can be coerced to that class): a symbolic description for the variables to be described.
data an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which lm is called.
drop if drop is TRUE, unused factor levels are dropped from the result when creating interaction terms. The default is to drop all unused factor levels.

Details

This is used by Desc.formula for describing data by groups while remaining flexible for using I(...) constructions, functions or interaction terms.

Value

a list of 3 elements

formula the formula which had to be parsed
lhs a list of 3 elements:
  mf: data.frame, the model.frame of the left hand side of the formula
  mf.eval: data.frame, the evaluated model.frame of the left hand side of the formula
  vars: the names of the evaluated model.frame
rhs a list of 3 elements:
  mf: data.frame, the model.frame of the right hand side of the formula
  mf.eval: data.frame, the evaluated model.frame of the right hand side of the formula
  vars: the names of the evaluated model.frame
Description

A parser for simple SAS dataline command texts. A data.frame is being built with the column-names listed in the input section. The data object will be created in the given environment.

Usage

ParseSASDatalines(x, env = .GlobalEnv, overwrite = FALSE)

Arguments

x the SAS text
env environment in which the dataset should be created.
logical. If set to TRUE, the function will silently overwrite a potentially existing object in env with the same name as declared in the SAS DATA section. If set to FALSE (default) an error will be raised if there already exists an object with the same name.

Details

The SAS function DATA is designed for quickly creating a dataset from scratch. The whole step normally consists out of the DATA part defining the name of the dataset, an INPUT line declaring the variables and a DATALINES command followed by the values.

The default delimiter used to separate the different variables is a space (thus each variable should be one word). The $ after the variable name indicates that the variable preceding contain character values and not numeric values. Without specific instructions, SAS assumes that variables are numeric. The function will fail, if it encounters a character in the place of an expected numeric value. Each new row in datalines will create a corresponding unique row in the dataset. Notice that a ; is not needed after every row, rather it is included at the end of the entire data step.

More complex command structures, i.e. other delimiters (dlm), in the INPUT-section are not (yet) supported.

Value

a data.frame

PasswordDlg  

**Description**

Brings up a tcltk dialog centered on the screen, designed for entering passwords while displaying only ****.

**Usage**

PasswordDlg()

**Value**

the entered password

**Author(s)**

Markus Naepflin <markus@naepfl.in>

**Examples**

```r
## Not run:
pw <- PasswordDlg()
pw
## End(Not run)
```

PDFManual  

**Get PDF Manual of a Package From CRAN**

**Description**

PDF versions of the manual are usually not included as vignettes in R packages. Still this format is convenient for reading and doing full text search.

This function creates the appropriate link to the pdf file on CRAN and opens the pdf manual in a browser window.

**Usage**

PDFManual(package)

**Arguments**

package name of the package.
Author(s)
Andri Signorell <andri@signorell.net>

Examples

## Not run:
PDFManual(DescTools)

## End(Not run)

PearsonTest

Pearson Chi-Square Test for Normality

Description
Performs the Pearson chi-square test for the composite hypothesis of normality.

Usage

PearsonTest(x, n.classes = ceiling(2 * (n^(2/5))), adjust = TRUE)

Arguments

x a numeric vector of data values. Missing values are allowed.
n.classes The number of classes. The default is due to Moore (1986).
adjust logical; if TRUE (default), the p-value is computed from a chi-square distribution
with n.classes-3 degrees of freedom, otherwise from a chi-square distribution
with n.classes-1 degrees of freedom.

Details
The Pearson test statistic is $P = \sum(C_i - E_i)^2/E_i$, where $C_i$ is the number of counted and $E_i$
the number of expected observations (under the hypothesis) in class $i$. The classes are build is
such a way that they are equiprobable under the hypothesis of normality. The p-value is computed
from a chi-square distribution with n.classes-3 degrees of freedom if adjust is TRUE and from a
chi-square distribution with n.classes-1 degrees of freedom otherwise. In both cases this is not
(!) the correct p-value, lying somewhere between the two, see also Moore (1986).

Value
A list of class htest, containing the following components:

- statistic the value of the Pearson chi-square statistic.
- p.value the p-value for the test.
- method the character string “Pearson chi-square normality test”.
- data.name a character string giving the name(s) of the data.
n.classes the number of classes used for the test.
df the degrees of freedom of the chi-square distribution used to compute the p-value.

Note

The Pearson chi-square test is usually not recommended for testing the composite hypothesis of normality due to its inferior power properties compared to other tests. It is common practice to compute the p-value from the chi-square distribution with \( n\cdot classes - 3 \) degrees of freedom, in order to adjust for the additional estimation of two parameters. (For the simple hypothesis of normality (mean and variance known) the test statistic is asymptotically chi-square distributed with \( n\cdot classes - 1 \) degrees of freedom.) This is, however, not correct as long as the parameters are estimated by \( \text{mean}(x) \) and \( \text{var}(x) \) (or \( \text{sd}(x) \)), as it is usually done, see Moore (1986) for details. Since the true p-value is somewhere between the two, it is suggested to run \( \text{PearsonTest} \) twice, with \( \text{adjust} = \text{TRUE} \) (default) and with \( \text{adjust} = \text{FALSE} \). It is also suggested to slightly change the default number of classes, in order to see the effect on the p-value. Eventually, it is suggested not to rely upon the result of the test.

The function call \( \text{PearsonTest}(x) \) essentially produces the same result as the S-PLUS function call \( \text{chisq.gof}((x-\text{mean}(x))/\text{sqrt} \cdot \text{var}(x)), n\cdot \text{param.est}=2) \).

PercTable

Percentage Table

Description

Prints a 2-way contingency table along with percentages, marginal, and conditional distributions. All the frequencies are nested into one single table.

Usage

```r
## Default S3 method:
PercTable(x, y = NULL, ...)

## S3 method for class 'table'
PercTable(tab, row.vars = NULL, col.vars = NULL, justify = "right",
          freq = TRUE, rfrq = "100", expected = FALSE, residuals = FALSE,
          stdres = FALSE, margins = NULL, digits = NULL, ...)

## S3 method for class 'formula'
PercTable(formula, data, subset, na.action, ...)

## S3 method for class 'PercTable'
print(x, vsep = NULL, ...)

Margins(tab, ...)
```

Arguments

- `x, y` objects which can be interpreted as factors (including character strings). `x` and `y` will be tabulated via `table(x, y)`. If `x` is a matrix, it will be coerced to a table via `as.table(x)`.
- `tab` a r x c-contingency table
- `row.vars` a vector of row variables (see Details).
- `col.vars` a vector of column variables (see Details). If this is left to NULL the table structure will be preserved.
- `justify` either "left" or "right" for defining the alignment of the table cells.
- `freq` boolean. Should absolute frequencies be included? Defaults to TRUE.
- `rfrq` a string with 3 characters, each of them being 1 or 0. The first position means total percentages, the second means row percentages and the third column percentages. "011" produces a table output with row and column percentages.
- `expected` the expected counts under the null hypothesis.
- `residuals` the Pearson residuals, (observed - expected) / sqrt(expected).
stdres

standardized residuals, (observed - expected) / sqrt(V), where V is the residual cell variance (for the case where x is a matrix, n * p * (1 - p) otherwise).

margins

a vector, consisting out of 1 and/or 2. Defines the margin sums to be included. 1 stands for row margins, 2 for column margins, c(1,2) for both. Default is NULL (none).

digits

integer. With how many digits should the relative frequencies be formatted? Default can be set by DescToolsOptions(digits=x).

formula

a formula of the form lhs ~ rhs where lhs will be tabled versus rhs (table(lhs,rhs)).

data

an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset

an optional vector specifying a subset of observations to be used.

na.action

a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

vsep

logical, defining if an empty row should be introduced between the table rows. Default is FALSE, if only a table with one single description (either frequencies or percents) should be returned and TRUE in any other case.

... the dots are passed from PercTable.default() to PercTable.table() and from Margins to the function Freq.

Details

PercTable prints a 2-dimensional table. The absolute and relative frequencies are nested into one flat table by means of `ftable`. `row.vars` resp. `col.vars` can be used to define the structure of the table. `row.vars` can either be the names of the dimensions (included percentages are named "idx") or numbers (1:3, where 1 is the first dimension of the table, 2 the second and 3 the percentages). Use Sort() if you want to have your table sorted by rows.

The style in which numbers are formatted is selected by `Fmt()` from the DescTools options. Absolute frequencies will use `Fmt("abs")` and `Fmt("per")` will do it for the percentages. The options can be changed with `Fmt(abs=as.fmt(...))` which is basically a "fmt"-object containing any format information used in `Format`.

Margins() returns a list containing all the one dimensional margin tables of a n-dimensional table along the given dimensions. It uses `margin.table()` for all the dimensions and adds the appropriate percentages.

Value

Returns an object of class "ftable".

There are similar functions in package `sfsmisc printTable2` and package `vcd table2d_summary`, both lacking some of the flexibility we needed here.

Examples

```r
# Perctable example

# Create a table
tab <- table(driver=d.pizza$driver, area=d.pizza$area)

# Call PercTable function
PercTable(tab=tab, col.vars=2)

# Call with margins
PercTable(tab=tab, col.vars=2, margins=c(1,2))
PercTable(tab=tab, col.vars=2, margins=2)
PercTable(tab=tab, col.vars=2, margins=1)
PercTable(tab=tab, col.vars=2, margins=NULL)

# Call with rfrq
PercTable(tab=tab, col.vars=2, rfrq="000")

# Just percentages without absolute values
PercTable(tab=tab, col.vars=2, rfrq="110", freq=FALSE)

# Just row percentages in percent format (pfmt = TRUE)
PercTable(tab, freq= FALSE, rfrq="010", pfmt=TRUE, digits=1)

# Just the expected frequencies and the standard residuals
PercTable(tab=tab, rfrq="000", expected = TRUE, stdres = TRUE)

# Rearrange output such that freq are inserted as columns instead of rows
PercTable(tab=tab, col.vars=c(3,2), rfrq="111")

# Putting the areas in rows
PercTable(tab=tab, col.vars=c(3,1), rfrq="100", margins=c(1,2))

# Formula interface with subset
PercTable(driver ~ area, data=d.pizza, subset=wine_delivered==0)

# Sort the table by rows, order first column (Zurich), then third, then row.names (0)
PercTable(tab=Sort(tab, ord=c(1,3,0)))

# Reverse the row variables, so that absolute frequencies and percents
# are not nested together
PercTable(tab, row.vars=c(3, 1))
```
# the vector interface
PermcTable(x=d.pizza$driver, y=d.pizza$area)
PermcTable(x=d.pizza$driver, y=d.pizza$area, margins=c(1,2), rfrq="000", useNA="ifany")

# one dimensional x falls back to the function Freq()
PermcTable(x=d.pizza$driver)

# the margin tables
Margins(Titanic)

---

**Permn**

Number and Samples for Permutations or Combinations of a Set

**Description**

Return the set of permutations for a given set of values. The values can be numeric values, characters or factors. **CombN** computes the number of combinations with and without replacement and order, whereas **CombSet** returns the value sets.

**Usage**

```r
Permn(x, sort = FALSE)
CombN(x, m, repl = FALSE, ord = FALSE)
CombSet(x, m, repl = FALSE, ord = FALSE, as.list = FALSE)
```

**Arguments**

- `x` a vector of numeric values or characters. Characters need not be unique.
- `m` number of elements to choose. For **CombSet** can `m` be a numeric vector too.
- `repl` logical. Should repetition of the same element be allowed? Defaults to FALSE
- `ord` logical. Does the order matter? Default is FALSE.
- `sort` logical, defining if the result set should be sorted. Default is FALSE.
- `as.list` logical, defining if the results should be returned in a flat list, say every sample is a single element of the resulting list. Default is FALSE.

**Details**

The vector `x` need not contain unique values. The permutations will automatically be filtered for unique sets, if the same element is given twice or more.

**Value**

- a matrix with all possible permutations or combinations of the values in `x` for **Permn** and **CombSet** if `m` contains more than one element the result will be a list of matrices or a flat list if `as.list` is set to TRUE
- an integer value for **CombN**

CombSet(x=x, m=c(1, 3, 5), as.list=TRUE)

Phrase

Phrasing Results of t-Test

Description

Formulating the results of a comparison of means is quite common. This function assembles a
descriptive text about the results of a t-test, describing group sizes, means, p-values and confidence
intervals.
Usage

Phrase(x, g, glabels = NULL, xname = NULL, unit = NULL, lang = "engl", na.rm = FALSE)

Arguments

x  a (non-empty) numeric vector of data values.
g  a vector or factor object giving the group for the corresponding elements of x. The number of levels must equal 2.
glabels  the labels of the two groups, if left to NULL, the levels will be used.
xname  the name of the variable to be used in the text.
unit  an optional unit for be appended to the numeric results.
lang  the language to be used. Only english (default) and german implemented (so far).
na.rm  logical, should NAs be omitted? Defaults to FALSE.

Value

a text

**PlotACF**

*Combined Plot of a Time Series and Its ACF and PACF*

Description

Combined plot of a time Series and its autocorrelation and partial autocorrelation
Usage

PlotACF(series, lag.max = 10 * log10(length(series)), ...)  
PlotGACF(series, lag.max = 10 * log10(length(series)), type = "cor", ylab = NULL, ...)

Arguments

series            univariate time series.
lag.max           integer. Defines the number of lags to be displayed. The default is 10 * log10(length(series)).
type              character string giving the type of acf to be computed. Allowed values are "cor" (the default), "cov" or "part" for autocorrelation, covariance or partial correlation.
ylab              a title for the y axis: see title.
...                the dots are passed to the plot command.

Details

PlotACF plots a combination of the time series and its autocorrelation and partial autocorrelation.  
PlotGACF is used as subfunction to produce the acf- and pacf-plots.

Author(s)

Markus Huerzeler (ETH Zurich), some minor modifications Andri Signorell <andri@signorell.net>

ts

Examples

PlotACF(AirPassengers)

Description

Produce a stacked area plot, or add polygons to an existing plot.

Usage

## Default S3 method:
PlotArea(x, y = NULL, prop = FALSE, add = FALSE, xlab = NULL, ylab = NULL, col = NULL, frame.plot = FALSE, ...)

## S3 method for class 'formula'
PlotArea(formula, data, subset, na.action, ...)
Arguments

x numeric vector of x values, or if y=NULL a numeric vector of y values. Can also be a 1-dimensional table (x values in names, y values in array), matrix or 2-dimensional table (x values in row names and y values in columns), a data frame (x values in first column and y values in subsequent columns), or a time-series object of class ts/ts.

y numeric vector of y values, or a matrix containing y values in columns.

prop whether data should be plotted as proportions, so stacked areas equal 1.

add whether polygons should be added to an existing plot.

xlab label for x axis.

ylab label for y axis.

col fill color of polygon(s). The default is a vector of gray colors.

frame.plot a logical indicating whether a box should be drawn around the plot.

formula a formula, such as y ~ x or cbind(y1,y2) ~ x, specifying x and y values. A dot on the left-hand side, formula = . ~ x, means all variables except the one specified on the right-hand side.

data a data frame (or list) from which the variables in formula should be taken.

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NA values. Defaults to getOption("na.action").

... further arguments are passed to matplot and polygon.

Value

Matrix of cumulative sums that was used for plotting.

### PlotBag

**Bivariate Boxplot**

**Description**

PlotBag() creates a two-dimensional boxplot called "bagplot" based on two numerical variables `x` and `y`. `plot.PlotBag()` is the plotting routine for a bagplot object. `compute.PlotBag()` contains the computation logic for the object.

**Usage**

```r
PlotBag(x, y, factor = 3, na.rm = FALSE, approx.limit = 300,
   show.outlier = TRUE, show.whiskers = TRUE,
   show.looppoints = TRUE, show.bagpoints = TRUE,
   show.loophull = TRUE, show.baghull = TRUE,
   create.plot = TRUE, add = FALSE, pch = 16, cex = 0.4,
   dkmethod = 2, precision = 1, verbose = FALSE,
   debug.plots = "no", col.loophull = "#aaccff",
   col.looppoints = "#3355ff", col.baghull = "#7799ff",
   col.bagpoints = "#000088", transparency = FALSE, ...)
```

```r
PlotBagPairs(dm, trim = 0.0, main, numeric.only = TRUE,
```
```r
factor = 3, approx.limit = 300, pch = 16,
cex = 0.8, precision = 1, col.loophull = "#aaccff",
col.loopponts = "#3355ff", col.baghull = "#7799ff",
col.bagpoints = "#000088", ...)

compute.bagplot(x, y, factor = 3, na.rm = FALSE, approx.limit = 300,
dkmethod = 2, precision = 1, verbose = FALSE, debug.plots = "no")

### S3 method for class 'bagplot'
plot(x, show.outlier = TRUE, show.whiskers = TRUE,
    show.looppoints = TRUE, show.bagpoints = TRUE,
    show.loophull = TRUE, show.baghull = TRUE, add = FALSE,
pch = 16, cex = .4, verbose = FALSE, col.loophull = "#aaccff",
col.loopponts = "#3355ff", col.baghull = "#7799ff",
col.bagpoints = "#000088", transparency = FALSE,...)
```

**Arguments**

- **x**: x values of a data set; in `PlotBag`: an object of class `PlotBag` computed by `compute.PlotBag`
- **y**: y values of the data set
- **factor**: factor defining the loop
- **na.rm**: if TRUE 'NA' values are removed otherwise exchanged by median
- **approx.limit**: if the number of data points exceeds `approx.limit` a sample is used to compute some of the quantities; default: 300
- **show.outlier**: if TRUE outlier are shown
- **show.whiskers**: if TRUE whiskers are shown
- **show.looppoints**: if TRUE loop points are plotted
- **show.bagpoints**: if TRUE bag points are plotted
- **show.loophull**: if TRUE the loop is plotted
- **show.baghull**: if TRUE the bag is plotted
- **create.plot**: if FALSE no plot is created
- **add**: if TRUE the bagplot is added to an existing plot
- **pch**: sets the plotting character
- **cex**: sets characters size
- **dkmethod**: 1 or 2, there are two method of approximating the bag, method 1 is very rough (only based on observations
- **precision**: precision of approximation, default: 1
- **verbose**: automatic commenting of calculations
- **debug.plots**: if TRUE additional plots describing intermediate results are constructed
- **col.loophull**: color of loop hull
A bagplot is a bivariate generalization of the well known boxplot. It has been proposed by Rousseeuw, Ruts, and Tukey. In the bivariate case the box of the boxplot changes to a convex polygon, the bag of bagplot. In the bag are 50 percent of all points. The fence separates points within the fence from points outside. It is computed by increasing the the bag. The loop is defined as the convex hull containing all points inside the fence. If all points are on a straight line you get a classical boxplot. 

In case you want to plot multiple (overlapping) bagplots, you may want plots that are semi-transparent. For this you can use the transparency flag. If \texttt{transparency==TRUE} the alpha layer is set to ‘99’ (hex). This causes the bagplots to appear semi-transparent, but ONLY if the output device is PDF and opened using: \texttt{pdf(file=’filename.pdf’,version=’1.4’)}. For this reason, the default is \texttt{transparency==FALSE}. This feature as well as the arguments to specify different colors has been proposed by Wouter Meuleman.

In the case of very large data sets subsets of the data are used for constructing the bagplot. A data set is very large if there are more data points than \texttt{approx.limit}. \texttt{xydata} are the input data structured in a two column matrix.

**Note**

Version of bagplot: 10/2012

PlotBubble

**Draw a Bubble Plot**

**Description**

Draw a bubble plot, defined by a pair of coordinates x, y to place the bubbles, an area definition configuring the dimension and a color vector setting the color of the bubbles. The legitimation to define a new function instead of just using plot(symbols(...)) is the automated calculation of the axis limits, ensuring that all bubbles will be fully visible.

**Usage**

PlotBubble(x, ...)

## Default S3 method:
PlotBubble(x, y, area, col = NA, cex = 1, border = par("fg"),
  xlim = NULL, ylim = NULL, na.rm = FALSE, ...)

## S3 method for class 'formula'
PlotBubble(formula, data = parent.frame(), ..., subset, ylab = varnames[response])

**Arguments**

- **x, y** the x and y co-ordinates for the centres of the bubbles. They can be specified in any way which is accepted by `xy.coords`.
- **area** a vector giving the area of the bubbles.
- **col** colors for the bubbles, passed to `symbol`. The default NA (or also NULL) means do not fill, i.e., draw transparent bubbles.
- **cex** extension factor for the area.
- **border** the border color for the bubbles. The default means `par("fg")`. Use `border = NA` to omit borders.
- **xlim, ylim** axes limits.
- **na.rm** logical, should NAs be omitted? Defaults to TRUE.
- **formula** a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
- **data** an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset** an optional vector specifying a subset of observations to be used.
- **ylab** the y-label for the plot used in the formula interface.
- **...** the dots are passed to the `plot` function.
PlotCandlestick

Details

Argument `inches` controls the sizes of the symbols. If `TRUE` (the default), the symbols are scaled so that the largest dimension of any symbol is one inch. If a positive number is given the symbols are scaled to make largest dimension this size in inches (so `TRUE` and 1 are equivalent). If `inches` is `FALSE`, the units are taken to be those of the appropriate axes. This behaviour is the same as in `symbols`.

Note

A legend can be added with `BubbleLegend`.

PlotBubble(x = state.x77[,"Income"], y = state.x77[,"Life Exp"], cex=.00004, 
  area = state.x77[,"Population"], col = cols[state.region], border="grey50", 
  panel.first=grid(), xlab="Income", ylab="Life Exp.", las=1
)

BubbleLegend(x = "topright", area = c(20000, 10000, 1000), cex=.00004, frame=NA, 
  cols=cols[1:3], labels = c(20000, 10000, 1000), cex.names=0.7)

legend(x="bottomright", fill=cols[1:4], legend=levels(state.region))
```

PlotCandlestick

Plot Candlestick Chart

Description

Plot a candlestick chart. This is used primarily to describe price movements of a security, derivative, or currency over time. Candlestick charts are a visual aid for decision making in stock, foreign exchange, commodity, and option trading.
Usage

PlotCandlestick(x, y, xlim = NULL, ylim = NULL, 
    col = c("springgreen4","firebrick"), 
    border = NA, args.grid = NULL, ...)

Arguments

x a numeric vector for the x-values. Usually a date.
y the y-values in a matrix (or a data.frame that can be coerced to a matrix) with 4 
columns, whereas the first column contains the open price, the second the high, 
the third the lowest and the 4th the close price of daily stock prices.
xlim the x limits (x1, x2) of the plot. The default value, NULL, indicates that the range 
of the finite values to be plotted should be used.
ylim the y limits of the plot.
col color for the body. To better highlight price movements, modern candlestick 
charts often replace the black or white of the candlestick body with colors such 
as red for a lower closing and blue or green for a higher closing.
border the border color of the rectangles. Default is NA, meaning no border will be 
plotted.
args.grid the arguments of a potential grid. Default is NULL, which will have a grid plotted. 
If arguments are provided, they have to be organized as list with the names of 
the arguments. (For example: ..., args.grid = list(col="red"))
...
the dots are passed to plot() command

Details

Candlesticks are usually composed of the body (black or white), and an upper and a lower shadow 
(wick): the area between the open and the close is called the real body, price excursions above and 
below the real body are called shadows. The wick illustrates the highest and lowest traded prices 
of a security during the time interval represented. The body illustrates the opening and closing 
trades. If the security closed higher than it opened, the body is white or unfilled, with the opening 
price at the bottom of the body and the closing price at the top. If the security closed lower than it 
opened, the body is black, with the opening price at the top and the closing price at the bottom. A 
candlestick need not have either a body or a wick.

```

PlotCashFlow

### Description

A cash flow plot is a plot used in finance and allows you to graphically depict the timing of the cash flows as well as their nature as either inflows or outflows. An "up" arrow represents money received and a "down" arrow money paid out.

### Usage

```r
PlotCashFlow(x, y, xlim = NULL, labels = y)
```

### Arguments

- `x` time period of the cashflows (in and out)
- `y` amount of the cashflows
- `xlim` range of the x-axis, defaults to `range(x)`.
- `labels` the labels of the cashflows will be printed outside the arrows.

Examples

PlotCashFlow(x=c(6:9, 13:15), y=-c(rep(40, 4), rep(50,3)),
xlim=c(6,17), labels=c(rep(40, 4), rep(50,3)))

PlotCashFlow(x=c(6,8,9,12,17), y=c(10,30,40,50,70))

PlotCirc

Plot Circular Plot

Description
This visualising scheme represents the unidirectional relationship between the rows and the columns of a contingency table.

Usage

PlotCirc(tab, acol = rainbow(sum(dim(tab))), aborder = "darkgrey",
rcol = SetAlpha(acol[1:nrow(tab)], 0.5), rborder = "darkgrey",
gap = 5, main = "", labels = NULL, cex.lab = 1.0, las = 1,
adj = NULL, dist = 2)

Arguments
dtabtab a table to be visualised.
dacolacol the colors for the peripheral annuli.
daborderaborder the border colors for the peripheral annuli.
drcolrcol the colors for the ribbons.
drborderrborder the border colors for the ribbons.
dgcdagap the gap between the entities in degrees.
dmaimaingap the main title, defaults to "".
dlablabelslables the labels. Defaults to the column names and rownames of the table.
dldaslasialignment of the labels, 1 means horizontal, 2 radial and 3 vertical.
dajdadjadjustments for the labels. (Left: 0, Right: 1, Mid: 0.5)
ddistdist gives the distance of the labels from the outer circle. Default is 2.
dcex.labcex.lab the character extension for the labels.
Details

The visual scheme of representing relationships can be applied to a table, given the observation that a table cell is a relationship (with a value) between a row and column. By representing the row and columns as segments along the circle, the information in the corresponding cell can be encoded as a link between the segments. In general, the cell represents a unidirectional relationship (e.g. row->column) - in this relationship the role of the segments is not interchangeable (e.g. (row,col) and (col,row) are different cells). To identify the role of the segment, as a row or column, the ribbon is made to terminate at the row segment but slightly away from the column segment. In this way, for a given ribbon, it is easy to identify which segment is the row and which is the column.

Value

the calculated points for the labels, which can be used to place userdefined labels.

Examples

tab <- matrix(c(2,5,8,3,10,12,5,7,15), nrow=3, byrow=FALSE)
dimnames(tab) <- list(c("A","B","C"), c("D","E","F"))
tab

PlotCirc(tab,
    acol = c("dodgerblue","seagreen2","limegreen","olivedrab2","goldenrod2","tomato2"),
    rcol = SetAlpha(c("red","orange","olivedrab1"), 0.5)
)

tab <- table(d.pizza$weekday, d.pizza$operator)
par(mfrow=c(1,2))
PlotCirc(tab, main="weekday ~ operator")
PlotCirc(t(tab), main="operator ~ weekday")
Description

This function produces a graphical display of a correlation matrix. The cells of the matrix can be shaded or colored to show the correlation value.

Usage

PlotCorr(x, cols = colorRampPalette(c(Pal()[2], "white", Pal()[1]), space = "rgb") (20),
breaks = seq(-1, 1, length = length(cols) + 1),
border = "grey", lwd = 1,
args.colorlegend = NULL, xaxt = par("xaxt"), yaxt = par("yaxt"),
cex.axis = 0.8, las = 2, mar = c(3, 8, 8, 8), mincor = 0,
main = "", clust = FALSE, ...)

Arguments

x  x is a correlation matrix to be visualized.
cols the colors for shading the matrix. Uses the package's option "col1" and "col2" as default.
breaks a set of breakpoints for the colours: must give one more breakpoint than colour. These are passed to image() function. If breaks is specified then the algorithm used follows cut, so intervals are closed on the right and open on the left except for the lowest interval.
border color for borders. The default is grey. Set this argument to NA if borders should be omitted.
lwd line width for borders. Default is 1.
args.colorlegend list of arguments for the ColorLegend. Use NA if no color legend should be painted.
xaxt parameter to define, whether to draw an x-axis, defaults to "n".
yaxt parameter to define, whether to draw an y-axis, defaults to "n".
cex.axis character extension for the axis labels.
las the style of axis labels.
mar sets the margins, defaults to mar = c(3, 8, 8, 8) as we need a bit more room on the right.
mincor numeric value between 0 and 1, defining the smallest correlation that is to be displayed. If this is >0 then all correlations with a lower value are suppressed.
main character, the main title.
clust logical. If set to TRUE, the correlations will be clustered in order to aggregate similar values.
... the dots are passed to the function image, which produces the plot.
Value

no values returned.

))
PlotCorr(m[idx, idx])
```

---

**PlotDot**

**Cleveland’s Dot Plots**

**Description**

Draw a Cleveland dot plot. This is an extended version of `dotchart` with an added option for error bars and an add argument.

**Usage**

```r
PlotDot(x, labels = NULL, groups = NULL, gdata = NULL,
        cex = par("cex"), pch = NULL, gpch = 21, bg = par("bg"),
        color = par("fg"), gcolor = par("fg"), lcolor = "gray", lbcolor = par("fg"),
        xlim = NULL, main = NULL, xlab = NULL, ylab = NULL,
        xaxt=NULL, yaxt=NULL, add = FALSE, args.errbars = NULL, ...)
```

**Arguments**

- **x**
  - either a vector or matrix of numeric values (NAs are allowed). If `x` is a matrix the overall plot consists of juxtaposed dotplots for each row. Inputs which satisfy `is.numeric(x)` but not `is.vector(x) || is.matrix(x)` are coerced by `as.numeric`, with a warning.
labels a vector of labels for each point. For vectors the default is to use names(x) and for matrices the row labels dimnames(x)[[1]].
groups an optional factor indicating how the elements of x are grouped. If x is a matrix, groups will default to the columns of x.
gdata data values for the groups. This is typically a summary such as the median or mean of each group.
cex the character size to be used. Setting cex to a value smaller than one can be a useful way of avoiding label overlap. Unlike many other graphics functions, this sets the actual size, not a multiple of par("cex").
pch the plotting character or symbol to be used. Default is 21.
gpch the plotting character or symbol to be used for group values.
bg the background color of plotting characters or symbols to be used; use par(bg=*) to set the background color of the whole plot.
color the color(s) to be used for points and labels.
gcolor the single color to be used for group labels and values.
lcolor the color(s) to be used for the horizontal lines.
lbicolor the color(s) to be used for labels.
xlim horizontal range for the plot, see plot.window, e.g.
main overall title for the plot, see title.
xlab, ylab axis annotations as in title.
xaxt a character which specifies the x axis type. Specifying "n" suppresses plotting of the axis.
yaxt a character which specifies the y axis type. Specifying "n" suppresses plotting of the axis.
add logical specifying if bars should be added to an already existing plot; defaults to FALSE.
args.errbars optional arguments for adding error bars. All arguments for ErrBars can be supplied. If left to NULL (default), no error bars will be plotted.
... graphical parameters can also be specified as arguments.

Details

This function is invoked for its side effect, which is to produce two variants of dotplots as described in Cleveland (1985).

Dot plots are a reasonable substitute for bar plots.

Value

Return the y-values used for plotting.

```

---

**PlotECDF**

**Empirical Cumulative Distribution Function**

**Description**

Faster alternative for plotting the empirical cumulative distribution function (ecdf). The function offers the option to construct the ecdf on the base of a histogram, which makes sense, when x is large. So the plot process is much faster, without loosing much precision in the details.

**Usage**

```r
PlotECDF(x, breaks = NULL, col = Pal()[1], ylab = "", lwd = 2,
 xlab = NULL, cex.axis = NULL, ...)
```

**Arguments**

- `x` numeric vector of the observations for ecdf.
- `breaks` will be passed directly to `hist`. If left to NULL, no histogram will be used.
- `col` color of the line.
- `ylab` label for the y-axis.
- `lwd` line width.
- `xlab` label for the x-axis.
- `cex.axis` cex for the axis
- `...` arguments to be passed to subsequent functions.
Details

The stats function `plot.ecdf` is fine for vectors that are not too large. However for \( n \sim 1e7 \) we would observe a dramatic performance breakdown (possibly in combination with the use of `do.call`).

`PlotECDF` is designed as alternative for quicker plotting the ecdf for larger vectors. If `breaks` are provided as argument, a histogram with that number of breaks will be calculated and the ecdf will use those frequencies instead of respecting every single point.

Note that a plot will rarely need more than \(~1’000\) points on `x` to have a sufficient resolution on usual terms. `PlotFdist` will also use this number of breaks by default.

Value

no value returned, use `plot.ecdf` if any results are required.

`plot.ecdf`, `PlotFdist`

Examples

```r
PlotECDF(d.pizza$temperature)
```

```r
# make large vector
x <- rnorm(n=1e7)
```

```r
# plot only 1000 points instead of 1e7
PlotECDF(x, breaks=1000)
```
Arguments

xy xy data matrix, rows represent individuals and columns attributes.

which.row defines a permutation of the rows of the input matrix.

fill logic. If set to TRUE, only the first nc attributes of the faces are transformed, nc is the number of columns of x.

nr number of columns of faces on graphics device

nc number of rows of faces

scale logic. If set to TRUE, attributes will be normalized.

byrow if(byrow==TRUE), x will be transposed.

main title.

labels character strings to use as names for the faces.

col a vector of colors used for the parts of the faces. Colors are recycled in the order: "nose", "eyes", "hair", "face", "lips", "ears". Default is NA, which will omit colors.

Details

The features parameters of this implementation are:

- 1 height of face
- 2 width of face
- 3 shape of face
- 4 height of mouth
- 5 width of mouth
- 6 curve of smile
- 7 height of eyes
- 8 width of eyes
- 9 height of hair
- 10 width of hair
- 11 styling of hair
- 12 height of nose
- 13 width of nose
- 14 width of ears
- 15 height of ears
For details look at the literate program of `faces`.

**Value**

Information about usage of variables for face elements is returned invisibly.

**Note**

Based on version 12/2009.

**Examples**

```r
PlotFaces(rbind(1:3,5:3,3:5,5:7))
data(longley)
PlotFaces(longley[1:9,])
set.seed(17)
PlotFaces(matrix(sample(1:1000,128,), 16, 8), main="random faces")
```
means <- lapply(iris[-5], tapply, iris$Species, mean)
m <- t(do.call(rbind, means))
m <- cbind(m, matrix(rep(1, 11*3), nrow=3))

# define the colors, first for all faces the same
col <- replicate(3, c("orchid1", "olivedrab", "goldenrod4",
                     "peachpuff", "darksalmon", "peachpuff3"))
rownames(col) <- c("nose","eyes","hair","face","lips","ears")
# change haircolor individually for each face
col[3, ] <- c("lightgoldenrod", "coral3", "sienna4")

z <- PlotFaces(m, nr=1, nc=3, col=col)

# print the used coding
print(z$info, right=FALSE)

---

PlotFdist  
**Frequency Distribution Plot**

**Description**

This function is designed to give a univariate graphic representation of a numeric vectors frequency distribution. It combines a histogram, a density curve, a boxplot and the empirical cumulative distribution function (ecdf) in one single plot. A rug as well as a model distribution curve (e.g. a normal curve) can optionally be superposed. This results in a dense and informative picture of the facts. Still the function remains flexible as all possible arguments can be passed to the single components (hist, boxplot etc.) as a list (see examples).

**Usage**

PlotFdist(x, main = deparse(substitute(x)), xlab = ",", xlim = NULL, 
args.hist = NULL, args.rug = NA, args.dens = NULL, 
args.curve = NA, args.boxplot = NULL, args.ecdf = NULL, 
args.curve.ecdf = NA, heights = NULL, pdist = NULL, 
na.rm = FALSE, cex.axis = NULL, cex.main = NULL, mar = NULL, las = 1)

**Arguments**

- **x**  
  the numerical variable, whose distribution is to be plotted.

- **main**  
  main title of the plot.

- **xlab**  
  label of the x-axis, defaults to ",". (The name of the variable is typically placed in the main title and would be redundant here.)

- **xlim**  
  range of the x-axis, defaults to a pretty range(x, na.rm = TRUE).
PlotFdist

args.hist list of additional arguments to be passed to the histogram hist(). The defaults chosen when setting args.hist = NULL are more or less the same as in hist. The argument type defines, whether a histogram ("hist") or a plot with type = "h" (for 'histogram' like vertical lines for mass representation) should be used. The arguments for a "h-plot" will be col, lwd, pch.col, pch, pch.bg for the line and for an optional point character on top. The default type used will be chosen on the structure of x. If x is an integer with up to 12 unique values there will be a 'h-plot' and else a histogram!

args.rug list of additional arguments to be passed to the function rug(). Use args.rug = NA if no rug should be added. This is the default. Use args.rug = NULL to add rug with reasonable default values.

args.dens list of additional arguments to be passed to density. Use args.dens = NA if no density curve should be drawn. The defaults are taken from density.

args.curve list of additional arguments to be passed to curve. This argument allows to add a fitted distribution curve to the histogram. By default no curve will be added (args.curve = NA). If the argument is set to NULL, a normal curve with mean(x) and sd(x) will be drawn. See examples for more details.

args.boxplot list of additional arguments to be passed to the boxplot boxplot(). The defaults are pretty much the same as in boxplot. The two additional arguments pch.mean (default 23) and col.meanci (default "grey80") control, if the mean is displayed within the boxplot. Setting those arguments to NA will prevent them from being displayed.

args.ecdf list of additional arguments to be passed to ecdf(). Use args.ecdf = NA if no empirical cumulation function should be included in the plot. The defaults are taken from plot.ecdf.

args.curve.ecdf list of additional arguments to be passed to curve. This argument allows to add a fitted distribution curve to the cumulative distribution function. By default no curve will be added (args.curve.ecdf = NA). If the argument is set to NULL, a normal curve with mean(x) and sd(x) will be drawn. See examples for more details.

heights heights of the plotparts, defaults to c(2,0.5,1.4) for the histogram, the boxplot and the empirical cumulative distribution function, resp. to c(2,1.5) for a histogram and a boxplot only.

pdist distances of the plotparts, defaults to c(0,0), say there will be no distance between the histogram, the boxplot and the ecdf-plot. This can be useful for instance in case that the x-axis has to be added to the histogram.

na.rm logical, should NAs be omitted? Histogram and boxplot could do without this option, but the density-function refuses to plot with missings. Defaults to FALSE.

cex.axis character extension factor for the axes.

cex.main character extension factor for the main title. Must be set in dependence of the plot parts in order to get a harmonic view.

mar A numerical vector of the form c(bottom, left, top, right) which gives the number of lines of outer margin to be specified on the four sides of the plot. The default is c(0,0,3,0).

las numeric in 0,1,2,3; the style of axis labels. See par.
Details

Performance has been significantly improved, but if x is growing large (n > 1e7) the function will take its time to complete. Especially the density curve and the ecdf, but as well as the boxplot (due to the chosen alpha channel) will take their time to calculate and plot. In such cases consider taking a sample, i.e. `PlotFdist(x[sample(length(x), size=5000)])`, the big picture of the distribution won’t usually change much.

    na.rm = TRUE, main = "Airquality - Ozone")

legend(x="topright",
    legend=c(expression(plain("gamma: ") * Gamma * " " * bgroup("(", k * " = " *
        over(bar(x)^2, s^2) * " , " * theta * plain(" = ") * over(s^2, bar(x)), ")") ),
        "kernel density"),
    fill=c(hecru, getOption("col1", hred)), text.width = 0.25)

---

**PlotFun**  

**Plot a Function**

### Description

Plots mathematical expressions in one variable using the formula syntax.

### Usage

```r
PlotFun(FUN, args = NULL, from = NULL, to = NULL, by = NULL,
    xlim = NULL, ylim = NULL, polar = FALSE, type = "l",
    col = par("col"), lwd = par("lwd"), lty = par("lty"),
    pch = NA, mar = NULL, add = FALSE, ...)
```

### Arguments

- **FUN**  
  a mathematical expression defined using the formula syntax: \( f(x) \sim x \). \( x \) and \( y \) can as well be functions of a parameter \( t \): \( y(t) \sim x(t) \) (see examples).

- **args**  
  a list of additional parameters defined in the expression besides the independent variable.

- **from, to**  
  the range over which the function will be plotted.

- **by**  
  number: increment of the sequence.

- **xlim, ylim**  
  NULL or a numeric vector of length 2; if non-NULL it provides the defaults for `c(from, to)` and, unless `add=TRUE`, selects the x-limits of the plot - see `plot.window`.

- **polar**  
  logical. Should polar coordinates be used? Defaults to `FALSE`.

- **type**  
  plot type: see `plot.default`
col colors of the lines.
lwd line widths for the lines.
lty line type of the lines.
pch plotting 'character', i.e., symbol to use.
mar A numerical vector of the form c(bottom, left, top, right) which gives
the number of lines of margin to be specified on the four sides of the plot. The
default is c(3, 3, 3, 3).
add logical; if TRUE add to an already existing plot; if NA start a new plot taking
the defaults for the limits and log-scaling of the x-axis from the previous plot. Taken
as FALSE (with a warning if a different value is supplied) if no graphics device
is open.
... the dots are passed to the plot, resp. lines function.

Details

A function can be plotted with `curve`. This function here adds some more features, one enabling
to use a formula for defining the function to plot. This enables as well a parametric equation to be entered straight forward. Parameters of a function can be set separatedly. The aspect ratio y/x will be set to 1 by default. (See `plot.window` for details.)

If the argument axes (given in the dots) is not set to FALSE centered axis at a horizontal and vertical
position of 0 will be drawn, containing major and minor ticks.

---

**PlotLinesA**

**Plot Lines**

---

**Description**

Plot the columns of one matrix against the columns of another. Adds a legend on the right at the endpoints of lines.
Usage

PlotLinesA(x, y, col = 1:5, lty = 1, lwd = 1, lend = par("lend"),
  xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL, xaxt = NULL, yaxt = NULL,
  cex = 1, args.legend = NULL, main = NULL, grid = TRUE, mar = NULL,
  pch = NA, pch.col = par("fg"), pch.bg = par("bg"), pch.cex = 1, ...)

Arguments

  x, y  vectors or matrices of data for plotting. The number of rows should match. If
         one of them are missing, the other is taken as y and an x vector of 1:n is used.
         Missing values (NAs) are allowed.

  col   vector of colors. Colors are used cyclically.

  lty, lwd, lend  vector of line types, widths, and end styles. The first element is for the first
                   column, the second element for the second column, etc., even if lines are not
                   plotted for all columns. Line types will be used cyclically until all plots are
                   drawn.

  xlab, ylab   titles for x and y axes, as in plot.

 xlim, ylim   ranges of x and y axes, as in plot.

  xaxt, yaxt  a character which specifies the x axis type. Specifying "n" suppresses plotting
              of the axis. The standard value is "s", any value other than "n" implies plotting.

  cex        character expansion factor relative to current par("cex").

  args.legend  list of additional arguments for the legend; names of the list are used as argument
                  names. If set to NA, the legend will be suppressed.

  main       an overall title for the plot.

  grid       logical adds an nx by ny rectangular grid to an existing plot.

  mar        the margins of the plot.

  pch        character string or vector of 1-characters or integers for plotting characters, see
              points. The first character is the plotting-character for the first plot, the second
              for the second, etc. The default is the digits (1 through 9, 0) then the lowercase
              and uppercase letters. If no points should be drawn set this argument to NA (this
              is the default).

  pch.col    vector of colors for the points. Colors are used cyclically. Ignored if pch = NA.

  pch.bg     vector of background (fill) colors for the open plot symbols given by pch = 21:25 as in points. The default is set to par("bg"). Ignored if pch = NA.

  pch.cex    vector of character expansion sizes, used cyclically. This works as a multiple of
              par("cex"). Default is 1.0. Ignored if pch = NA.

  ... the dots are sent to matplot.

Details

This function is rather a template, than a function. It wraps matplot to generate a lines plot and
adds a rather sophisticated legend on the right side, while calculating appropriate margins. A grid
option is included (as panel.first does not work in matplot).
As in matplot, the first column of x is plotted against the first column of y, the second column of x against the second column of y, etc. If one matrix has fewer columns, plotting will cycle back through the columns again. (In particular, either x or y may be a vector, against which all columns of the other argument will be plotted.)

# example from MASS
shoes <- list(
              A = c(13.2, 8.2, 10.9, 14.3, 10.7, 6.6, 9.5, 10.8, 8.8, 13.3),
              B = c(14, 8.8, 11.2, 14.2, 11.8, 6.4, 9.8, 11.3, 9.3, 13.6))

PlotLinesA(do.call(rbind, shoes), xlim=c(0.75,2.25), col=1, main="shoes",
            pch=21, pch.bg="white", pch.col=1, pch.cex=1.5)

# let's define some arbitrary x-coordinates
PlotLinesA(x=c(1,2,6,8,15), y=VADeaths)

PlotLog

Logarithmic Plot

Description

The base function grid() does not support logarithmic scales very well. Especially when more lines are required, grids have to be created manually. PlotLog creates a plot with at least one logarithmic axis and places a logarithmic grid in the background of the data.

Usage

PlotLog(x, ..., args.grid = NULL, log = "xy")
Arguments

x  the coordinates of points in the plot. Alternatively, a single plotting structure, function or any R object with a plot method can be provided.

...  the dots are passed on to the function plot().

args.grid  a list of arguments for the grid. This contains line type, line width and line color, separately for major gridlines and for minor gridlines. 

args.grid=list(lwd=1,lty=3,col="grey85",col.min="grey60") are used as default. If the argument is set to NA, no grid will be plotted.

log  a character string which contains "x" if the x axis is to be logarithmic, "y" if the y axis is to be logarithmic and "xy" or "yx" if both axes are to be logarithmic.

Value

nothing

Author(s)

Andri Signorell <andri@signorell.net>

axis

Examples

PlotLog(brain ~ body, data=MASS::Animals, log="xy", 
xlim=c(.01, 1e5), ylim=c(.1, 1e4), main="Animal brain/body size", 
pch=21, bg="grey", cex=1.5)
Arguments

x     numeric vector of x values.
y     numeric vector of y values (of same length as x).
grp    grouping variable(s), typically factor(s), all of the same length as x.
xlim    the x limits of the plot.
ylim    the y limits of the plot.
col    the colors for lines and points. Uses rainbow() colors by default.
mardens which marginal densities to plot. Can be set to either just x or y, or both ("all", latter being the default).
pch    a vector of plotting characters or symbols.
pch.cex magnification to be used for plotting characters relative to the current setting of cex.
main    a main title for the plot, see also title.
na.rm logical, should NAs be omitted? Defaults to FALSE.
args.legend list of additional arguments for the legend. args.legend set to NA prevents a legend from being drawn.
args.dens list of additional arguments to be passed to density. Use args.dens = NA if no density curve should be drawn. The defaults are taken from density.
... further arguments are passed to the function plot().

Examples

# best seen with: x11(7.5, 4.7)

# just one variable with marginal densities
PlotMarDens( y=d.pizza$temperature, x=d.pizza$delivery_min, grp=1
    , xlab="delivery_min", ylab="temperature", col=SetAlpha("brown", 0.4)
    , pch=15, lwd=3
    , panel.first= grid(), args.legend=NA
    , main="Temp ~ delivery"
)

# use a group variable
PlotMarDens( y=d.pizza$temperature, x=d.pizza$delivery_min, grp=d.pizza$area
    , xlab="delivery_min", ylab="temperature", col=c("brown","orange","lightsteelblue")
    , panel.first=list( grid() )
    , main = "temperature ~ delivery_min | area"
)
# reset layout
par(mfrow=c(1,1))
**PlotMiss**  
*Plot Missing Data*

**Description**
Takes a data frame and displays the location of missing data. The missings can be clustered and be displayed together.

**Usage**
```r
PlotMiss(x, col = hred, bg = SetAlpha(hecru, 0.3), clust = FALSE, 
       main = NULL, ...)
```

**Arguments**
- `x`: a data.frame to be analysed.
- `col`: the colour of the missings.
- `bg`: the background colour of the plot.
- `clust`: logical, defining if the missings should be clustered. Default is `FALSE`.
- `main`: the main title.
- `...`: the dots are passed to `plot`.

**Details**
A graphical display of the position of the missings can be help to detect dependencies or patterns within the missings.

**Value**
if clust is set to TRUE, the new order will be returned invisibly.

**Author(s)**
Andri Signorell <andri@signorell.net>, following an idea of Henk Harmsen <henk@carbonmetrics.com>

**See Also**
- `hclust`, `CountCompCases`

**Examples**
```r
PlotMiss(d.pizza, main="Missing pizza data")
```
Description

Plot monthly or seasonal effects of a univariate time series

Usage

PlotMonth(x, type = "l", labels, xlab = "", ylab = deparse(substitute(x)), ...)

Arguments

x univariate time series

labels todo

type todo

xlab a title for the x axis: see title.

ylab a title for the y axis: see title.

... the dots are passed to the plot command.

Details

todo

Author(s)

Markus Huerzeler, ETH Zurich

See Also

ts

Examples

PlotMonth(AirPassengers)
Description

Plots a mosaic on the current graphics device.

Usage

PlotMosaic(x, main = deparse(substitute(x)), horiz = TRUE, cols = NULL,
off = 0.02, mar = NULL, xlab = NULL, ylab = NULL,
cex = par("cex"), las = 2, ...)

Arguments

x          a contingency table in array form, with optional category labels specified in the
dimnames(x) attribute. The table is best created by the table() command. So far
only 2-way tables are allowed.
main       character string for the mosaic title.
horiz      logical, defining the orientation of the mosaicplot. TRUE (default) makes a hori-
           zontal plot.
cols       the colors of the plot.
off         the offset between the rectangles. Default is 0.02.
mar         the margin for the plot.
xlab, ylab  x- and y-axis labels used for the plot; by default, the first and second element of
            names(dimnames(X)) (i.e., the name of the first and second variable in X).
cex         numeric character expansion factor; multiplied by par("cex") yields the final
            character size. NULL and NA are equivalent to 1.0.
las         the style of axis labels. 0 - parallel to the axis, 1 - horizontal, 2 - perpendicular,
            3 - vertical.
...         additional arguments are passed to the text function.

Details

The reason for this function to exist are the unsatisfying labels in base mosaicplot.

Value

list with the midpoints of the rectangles

Author(s)

Andri Signorell <andri@signorell.net>
PlotMultiDens

References

mosaicplot

Examples

PlotMosaic(HairEyeColor[,1])

PlotMultiDens  Plot Multiple Density Curves

Description

Multiple density curves are plotted on the same plot. The function plots the density curves in the defined colors and linetypes, after having calculated the globally appropriate xlim- and ylim-values. A legend can directly be included.

Usage

PlotMultiDens(x, ...)

## Default S3 method:
PlotMultiDens(x, xlim = NULL, ylim = NULL, col = Pal(), lty = "solid",
lwd = 2, fill = NA, xlab = "x", ylab = "density", args.dens = NULL,
args.legend = NULL, na.rm = FALSE, flipxy = FALSE, ...)  

## S3 method for class 'formula'
PlotMultiDens(formula, data, subset, na.action, ...)

Arguments

x a list of vectors whose densities are to be plotted. Use split to separate a vector by groups. (See examples)
xlim, ylim xlim, ylim of the plot.
col colors of the lines, defaults to Pal(), returning the default palette.
lty line type of the lines.
lwd line widths for the lines.
fill colors for fill the area under the density curve. If set to NA (default) there will be no color.
xlab, ylab a title for the x, resp. y axis. Defaults to "x" and "density".
args.dens  list of additional arguments to be passed to the density function. If set to NULL the defaults will be used. Those are \(n = 4096\) \((2^{12})\) and kernel = "epanechnikov".

args.legend  list of additional arguments to be passed to the legend function. Use args.legend = NA if no legend should be added.

na.rm  should NAs be omitted? Defaults to FALSE.

flipxy  logical, should x- and y-axis be flipped? Defaults to FALSE.

formula  a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data  an optional matrix or data frame (or similar: see \texttt{model.frame}) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset  an optional vector specifying a subset of observations to be used.

na.action  a function which indicates what should happen when the data contain NAs. Defaults to \texttt{getOption("na.action")}.

...  the dots are passed to plot(...).

Details

All style arguments, density arguments and data list elements will be recycled if necessary. The argument \texttt{flipxy} leads to exchanged x- and y-values. This option can be used to plot density curves with a vertical orientation for displaying marginal densities.

Value

data.frame with 3 columns, containing the \texttt{bw}, \texttt{n} and \texttt{kernel} parameters used for the list elements. The number of rows correspond to the length of the list \texttt{x}.

Note

Consider using:

```r
library(lattice)
densityplot(~ delivery_min | driver, data=d.pizza)
```

as alternative when not all curves should be plotted in the same plot.

Examples

```r
x <- rnorm(1000,0,1)
y <- rnorm(1000,0,2)
z <- rnorm(1000,2,1.5)

# the input of the following function MUST be a numeric list
PlotMultiDens(list(x=x,y=y,z=z))

# use area fill
PlotMultiDens(list(x=x,y=y,z=z), fill=SetAlpha(c("red","green","blue"), 0.4))

PlotMultiDens( x=split(d.pizza$delivery_min, d.pizza$driver), na.rm=TRUE
, main="delivery time ~ driver", xlab="delivery time [min]", ylab="density"
, lwd=1:7, lty=1:7
, panel.first=grid())

# this example demonstrates the definition of different line types and -colors
# an is NOT thought as recommendation for good plotting practice... :-)

# the formula interface
PlotMultiDens(delivery_min ~ driver, data=d.pizza)

# recycling of the density parameters
res <- PlotMultiDens(x=split(d.pizza$temperature, d.pizza$driver),
  args.dens = list(bw=c(5,2), kernel=c("rect","epanechnikov")), na.rm=TRUE)
res

# compare bandwidths
PlotMultiDens(x=split(d.pizza$temperature, d.pizza$driver)[1],
  args.dens = list(bw=c(1:5)), na.rm=TRUE,
  args.legend=NA, main="Compare bw")
legend(x="topleft", legend=gettextf("bw = %s", 1:5), fill=rainbow(5))
```

---

**PlotPairs**

**Extended Scatterplot Matrices**

**Description**

A matrix of scatterplots is produced. The upper triangular matrices contain nothing else than the correlation coefficient. The diagonal displays a histogram of the variable. The lower triangular matrix displays a scatterplot superposed by a smoother. It’s possible to define groups to be differentiated by color and also by individual smoothers. The used code is not much more than the `pairs()` code and some examples, but condenses it to a practical amount.

**Usage**

```r
PlotPairs(x, g = NULL, col = 1, pch = 19, col.smooth = 1, main = "",
  upper = FALSE, ...)
```
Arguments

- **x**: the coordinates of points given as numeric columns of a matrix or data frame. Logical and factor columns are converted to numeric in the same way that `data.matrix` does. Will directly be passed on to `pairs`.
- **g**: a group variable
- **col**: color for point character
- **pch**: point character
- **col.smooth**: color for the smoother(s)
- **main**: the main title
- **upper**: logical, determines if the correlation coefficients should be displayed in the upper triangular matrix (default) or in the lower one.
- **...**: additional arguments passed to `pairs` function.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

- `pairs`

Examples

```r
PlotPairs(iris[,1:4], g=iris$Species, main = "Anderson's Iris Data -- 3 species",
col=c(hred, hblue, hgreen), col.smooth=c("black", hred, hblue, hgreen))
```

---

PlotPolar

**Plot Values on a Circular Grid**

Description

PlotPolar creates a polar coordinate plot of the radius r in function of the angle theta. 0 degrees is drawn at the 3 o’clock position and angular values increase in a counterclockwise direction.

Usage

```r
PlotPolar(r, theta = NULL, type = "p", rlim = NULL, main = "", lwd = par("lwd"),
lty = par("lty"), col = par("col"), pch = par("pch"), fill = NA,
cex = par("cex"), mar = c(2, 2, 5, 2), add = FALSE, ...)
```
Arguments

- **r**: a vector of radial data.
- **theta**: a vector of angular data specified in radians.
- **type**: one out of c("p", "l", "h"), the plot type, defined following the definition in plot type. "p" means points, "l" will connect the points with lines and "h" is used to plot radial lines from the center to the points. Default is "p".
- **rlim**: the r limits (r1, r2) of the plot.
- **main**: a main title for the plot, see also title.
- **lwd**: a vector of line widths, see par.
- **lty**: a vector of line types, see par.
- **col**: The colors for lines and points. Multiple colors can be specified so that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in the first colour specified.
- **pch**: a vector of plotting characters or symbols: see points.
- **fill**: fill color, defaults to NA (none).
- **cex**: a numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of par("cex"). NULL and NA are equivalent to 1.0.
- **mar**: A numerical vector of the form c(bottom, left, top, right) which gives the number of lines of margin to be specified on the four sides of the plot.
- **add**: defines whether points should be added to an existing plot.
- **...**: further arguments are passed to the plot command.

Details

The function is rather flexible and can produce quite a lot of different plots. So it is also possible to create spider webs or radar plots.

**PlotPyramid**

*Draw a Back To Back Pyramid Plot*

**Description**

Pyramid plots are a common way to display the distribution of age groups.

**Usage**

```r
PlotPyramid(lx, rx = NA, ylab = "", ylab.x = 0,  
  col = c("red", "blue"), border = par("fg"),  
  main = "", lxlab = "", rxlab = "")
```
xlim = NULL, gapwidth = NULL,
xaxt = TRUE, args.grid = NULL, cex.axis = par("cex.axis"),
cex.lab = par("cex.axis"), cex.names = par("cex.axis"),
adj = 0.5, rev = FALSE, ...)

Arguments

1x either a vector or matrix of values describing the bars which make up the plot.
If 1x is a vector, it will be used to construct the left barplot. If 1x is a matrix the
first column will be plotted to the left side and the second to the right side. Other
columns are ignored.

rx a vector with the values used to build the right barplot. 1x and rx should be of
equal length.

ylab a vector of names to be plotted either in the middle or at the left side of the plot.
If this argument is omitted, then the names are taken from the names attribute of
1x if this is a vector.

ylab.x the x-position of the y-labels.

col the color(s) of the bars. If there are more than one the colors will be recycled.

border the border color of the bars. Set this to NA if no border is to be plotted.

main overall title for the plot.

1xlabel a label for the left x axis.

rxlabel a label for the right x axis.

xlim limits for the x axis. The first value will determine the limit on the left, the
second the one on the right.

gapwidth the width of a gap in the middle of the plot. If set to 0, no gap will be plotted.
Default is NULL which will make the gap as wide, as it is necessary to plot the
longest ylab.

xaxt a character which specifies the x axis type. Specifying "n" suppresses plotting
of the axis.

args.grid list of additional arguments for the grid. Set this argument to NA if no grid should
be drawn.

cex.axis expansion factor for numeric axis labels.

cex.lab expansion factor for numeric variable labels.

cex.names expansion factor for y labels (names).

adj one or two values in [0, 1] which specify the x (and optionally y) adjustment of
the labels.

rev logical, if set to TRUE the order of data series and names will be reversed.

... the dots are passed to the barplot function.
Details

Pyramid plots are a common way to display the distribution of age groups in a human population. The percentages of people within a given age category are arranged in a barplot, typically back to back. Such displays can be used to distinguish males vs. females, differences between two different countries or the distribution of age at different timepoints. The plot type can also be used to display other types of opposed bar charts with suitable modification of the arguments.

Value

A numeric vector giving the coordinates of all the bar midpoints drawn, useful for adding to the graph.

PlotQQ  

QQ-Plot for Any Distribution

Description

Create a QQ-plot for a variable of any distribution. The assumed underlying distribution can be defined as a function of f(p), including all required parameters. Confidence bands are provided by default.

Usage

PlotQQ(x, qdist=qnorm, main = NULL, xlab = NULL, ylab = NULL, datax = FALSE, add = FALSE, 
    args.qqline = NULL, conf.level = 0.95, args.cband = NULL, ...)

Arguments

x  the data sample
qdist  the quantile function of the assumed distribution. Can either be given as simple function name or defined as own function using the required arguments. Default is qnorm(). See examples.
main  the main title for the plot. This will be "Q-Q-Plot" by default
xlab  the xlab for the plot
ylab  the ylab for the plot
datax  logical. Should data values be on the x-axis? Default is FALSE.
add  logical specifying if the points should be added to an already existing plot; defaults to FALSE.
args.qline arguments for the qqline. This will be estimated as a line through the 25% and 75% quantiles by default, which is the same procedure as \texttt{qqline()} does for normal distribution (instead of set it to \texttt{abline(a = 0, b = 1)}). The quantiles can however be overwritten by setting the argument \texttt{probs} to some user defined values. Also the method for calculating the quantiles can be defined (default is 7, see \texttt{quantile}). The line defaults are set to \texttt{col = par("fg")}, \texttt{lwd = par("lwd")} and \texttt{lty = par("lty")}. No line will be plotted if \texttt{args.qqline} is set to \texttt{NA}.

conf.level confidence level for the confidence interval. Set this to \texttt{NA}, if no confidence band should be plotted. Default is 0.95. The confidence intervals are calculated pointwise method based on a Kolmogorov-Smirnov distribution.

args.cband list of arguments for the confidence band, such as color or border (see \texttt{DrawBand}).

... the dots are passed to the \texttt{plot} function.

Details
The function generates a sequence of points between 0 and 1 and transforms those into quantiles by means of the defined assumed distribution.

Note
The code is inspired by the tip 10.22 "Creating other Quantile-Quantile plots" from R Cookbook and based on R-Core code from the function \texttt{qqline}. The calculation of confidence bands are rewritten based on an algorithm published in the package \texttt{BoutrosLab.plotting.general}.

w <- rweibull(100, shape=2)
PlotQQ(w, qdist = function(p) qweibull(p, shape=4))

z <- rchisq(100, df=5)
PlotQQ(z, function(p) qchisq(p, df=5),
    args.qqline=list(col=2, probs=c(0.1, 0.6)),
    main=expression("Q-Q plot for" ~~ \{chi^2\}[nu == 3]))
abline(0,1)
\end{verbatim}
408

PlotTernary
# add 5 random sets
for(i in 1:5){
z <- rchisq(100, df=5)
PlotQQ(z, function(p) qchisq(p, df=5), add=TRUE, args.qqline = NA,
col="grey", lty="dotted")
}

PlotTernary

Ternary or Triangular Plots

Description
PlotTernary plots in a triangle the values of three variables. Useful for mixtures (chemistry etc.).
Usage
PlotTernary(x, y = NULL, z = NULL, args.grid = NULL, lbl = NULL, main = "",...)
Arguments
x

vector of first variable. Will be placed on top of the triangle.

y

vector of second variable (the right corner).

z

vector of third variable (on the left corner).

args.grid

list of additional arguments for the grid. Set this argument to NA if no grid should
be drawn. The usual color and linetype will be used.

main

overall title for the plot.

lbl

the labels for the corner points. Default to the names of x, y, z.

...

the dots are sent to points

## End(Not run)

PlotTreemap

Create a Treemap

Description

Creates a treemap where rectangular regions of different size, color, and groupings visualize the elements.

Usage

PlotTreemap(x, grp = NULL, labels = NULL, cex = 1, text.col = "black",
            col = rainbow(length(x)), labels.grp = NULL, cex.grp = 3,
            text.col.grp = "black", border.grp = "grey50",
            lwd.grp = 5, main = "")

Arguments

- **x**: a vector storing the values to be used to calculate the areas of rectangles.
- **grp**: a vector specifying the group (i.e. country, sector, etc.) to which each element belongs.
- **labels**: a vector specifying the labels.
- **cex**: the character extension for the area labels. Default is 1.
- **text.col**: the text color of the area labels. Default is "black".
- **col**: a vector storing the values to be used to calculate the color of rectangles.
- **labels.grp**: a character vector specifying the labels for the groups.
- **cex.grp**: the character extension for the group labels. Default is 3.
text.col.grp  the text color of the group labels. Default is "black".

border.grp   the border color for the group rectangles. Default is "grey50". Set this to NA if no special border is desired.

lwd.grp      the linewidth of the group borders. Default is 5.

main         a title for the plot.

Details

A treemap is a two-dimensional visualization for quickly analyzing large, hierarchical data sets. Treemaps are unique among visualizations because they provide users with the ability to see both a high level overview of data as well as fine-grained details. Users can find outliers, notice trends, and perform comparisons using treemaps. Each data element contained in a treemap is represented with a rectangle, or a cell. Treemap cell arrangement, size, and color are each mapped to an attribute of that element. Treemap cells can be grouped by common attributes. Within a group, larger cells are placed towards the bottom left, and smaller cells are placed at the top right.

Value

returns a list with groupwise organized midpoints in x and y for the rectangles within a group and for the groups themselves.

**PlotVenn**  
*Plot a Venn Diagram*

**Description**

This function produces Venn diagrams for up to 5 datasets.

**Usage**

```r
PlotVenn(x, col = "transparent", plotit = TRUE, labels = NULL)
```

**Arguments**

- `x`: the list with the sets to be analysed. Those can be factors or something coercable to a factor.
- `col`: the colors for the sets on the plot.
- `plotit`: logical. Should a plot be produced or just the results be calculated.
- `labels`: special labels for the plot. By default the names of the list `x` will be used. If those are missing, the LETTERS A..E will be chosen. Set this argument to NA, if no labels at all should be plotted.

**Details**

The function calculates the necessary frequencies and plots the venn diagram.

**Value**

a list with 2 elements, the first contains a table with the observed frequencies in the given sets. The second returns a data.frame with the xy coordinates for the labels in the venn diagram, the specific combination of factors and the frequency in that intersection area. The latter can be 0 as well.

r.venn
```

PlotViolin

*Plot Violins Instead of Boxplots*

Description

This function serves the same utility as side-by-side boxplots, only it provides more detail about the different distribution. It plots violins instead of boxplots. That is, instead of a box, it uses the density function to plot the density. For skewed distributions, the results look like "violins". Hence the name.

Usage

```r
PlotViolin(x, ...)
```

## Default S3 method:

```r
PlotViolin(x, ..., horizontal = FALSE, bw = "SJ", na.rm = FALSE,
   names = NULL, args.boxplot = NULL)
```

## S3 method for class 'formula'

```r
PlotViolin(formula, data, subset, na.action, ...)
```
Arguments

x Either a sequence of variable names, or a data frame, or a model formula
horizontal logical indicating if the density plots should be horizontal; default FALSE means vertical arrangement.
bw the smoothing bandwidth (method) being used by density. bw can also be a character string giving a rule to choose the bandwidth. See bw.nrd. The default has been switched from "nrd0" to "SJ", following the general recommendation in Venables & Ripley (2002).
In case of a method, the average computed bandwidth is used.
na.rm logical, should NAs be omitted? The density-function can't do with missings. Defaults to FALSE.
names a vector of names for the groups.
formula a formula, such as y ~ grp, where y is a numeric vector of data values to be split into groups according to the grouping variable grp (usually a factor).
data a data.frame (or list) from which the variables in formula should be taken.
subset an optional vector specifying a subset of observations to be used for plotting.
na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
... The dots are passed to polygon. Notably, you can set the color to red with col="red", and a border color with border="blue"
args.boxplot list of arguments for a boxplot to be superposed to the densityplot. By default (NULL) a black boxplot will be drawn. Set this to NA to suppress the boxplot.

Value

If a boxplot was drawn then the function returns a list with the following components:

stats a matrix, each column contains the extreme of the lower whisker, the lower hinge, the median, the upper hinge and the extreme of the upper whisker for one group/plot. If all the inputs have the same class attribute, so will this component.
n a vector with the number of observations in each group.
conf a matrix where each column contains the lower and upper extremes of the notch.
out the values of any data points which lie beyond the extremes of the whiskers.
group a vector of the same length as out whose elements indicate to which group the outlier belongs.
names a vector of names for the groups.

Note

This function is based on violinplot (package UsingR). Some adaptions were made in the interface, such as to accept the same arguments as boxplot does. Moreover the function was extended by the option to have a boxplot superposed.
Author(s)

John Verzani, Andri Signorell <andri@signorell.net>

References

The code is based on the boxplot function from R/base.

Examples

# make a "violin"
x <- c(rnorm(100), rnorm(50,5))

PlotViolin(x, col = "brown")

par(mfrow=c(1,2))
f <- factor(rep(1:5, 30))
# make a quintet. Note also choice of bandwidth
PlotViolin(x ~ f, col = SetAlpha("steelblue",0.3), bw = "SJ", main="Vertical")

# and the same, but in horizontal arrangement
PlotViolin(x ~ f, col = SetAlpha("steelblue",0.3), bw = "SJ", horizontal = TRUE,
             las=1, main="Horizontal")

# example taken from boxplot
boxplot(count ~ spray, data = InsectSprays, col = "lightgray", main="Boxplot")
PlotViolin(count ~ spray, data = InsectSprays, col = "lightgray", main="Violinplot")

# groupwise density plots defined the same way as in boxplot
boxplot(len ~ supp*dose, data = ToothGrowth,
        main = "Guinea Pigs' Tooth Growth",
        xlab = "Vitamin C dose mg", ylab = "tooth length",
        col=c("yellow", "orange"), lty=c(1,2))

b <- PlotViolin(len ~ supp*dose, data = ToothGrowth,
                main = "Guinea Pigs' Tooth Growth",
                xlab = "Vitamin C dose mg", ylab = "tooth length",
                col=c("yellow", "orange"), lty=c(1,2))

# use points, if the medians deserve special attention
points(x=1:6, y=b$stats[3,], pch=21, bg="white", col="black", cex=1.2)
Description

This plot can be used to graphically display a correlation matrix by using the linewidth between the nodes in proportion to the correlation of two variables. It will place the elements homogenously around a circle and draw connecting lines between the points.

Usage

PlotWeb(m, col = c(hred, hblue), lty = NULL, lwd = NULL, args.legend=NULL, pch = 21, pt.cex = 2, pt.col = "black", pt.bg = "darkgrey", cex.lab = 1, las = 1, adj = NULL, dist = 0.5, ...)

Arguments

m a symmetric matrix of numeric values
col the color for the connecting lines
lty the line type for the connecting lines, the default will be par("lty").
lwd the line widths for the connecting lines. If left to NULL it will be linearly scaled between the minimum and maximum value of m.
args.legend list of additional arguments to be passed to the legend function. Use args.legend = NA if no legend should be added.
pch the plotting symbols appearing in the plot, as a non-negative numeric vector (see points, but unlike there negative values are omitted) or a vector of 1-character strings, or one multi-character string.
pt.cex expansion factor(s) for the points.
pt.col the foreground color for the points, corresponding to its argument col.
pt.bg the background color for the points, corresponding to its argument bg.
las alignment of the labels, 1 means horizontal, 2 radial and 3 vertical.
adj adjustments for the labels. (Left: 0, Right: 1, Mid: 0.5)
dist gives the distance of the labels from the outer circle. Default is 2.
cex.lab the character extension for the labels.
... dots are passed to plot.

Details

The function uses the lower triangular matrix of m, so this is the order colors, linewidth etc. must be given, when the defaults are to be overrun.

Value

A list of x and y coordinates, giving the coordinates of all the points drawn, useful for adding other elements to the plot.

PlotCorr

Examples

```r
m <- cor(d.pizza[, which(sapply(d.pizza, IsNumeric, na.rm=TRUE))[-c(1:2)]],
    use="pairwise.complete.obs")
PlotWeb(m=m, col=c(hred, hblue), main="Pizza Correlation")

# let's describe only the significant corrs and start with a dataset
d.m <- d.pizza[, which(sapply(d.pizza, IsNumeric, na.rm=TRUE))[-c(1:2)]]

# get the correlation matrix
m <- cor(d.m, use="pairwise.complete.obs")

# let's get rid of all non significant correlations
cctest <- PairApply(d.m, function(x, y) cor.test(x, y)$p.value, symmetric=TRUE)

# ok, got all the p-values, now replace > 0.05 with NAs
m[cctest > 0.05] <- NA
# How does that look like now?
Format(m, na.form = ". ", leading="drop", digits=3, align = "right")

PlotWeb(m, las=2, cex=1.2)

# define line widths
PlotWeb(m, lwd=abs(m[lower.tri(m)] * 10))
```

PMT

Periodic Payment of an Annuity.

Description

PMT computes the periodic payment of an annuity. IPMT calculates what portion of a period payment is going towards interest in a particular period and PPMT what portion of a period payment is going towards principal in a particular period. RBAL yields the remaining balance in a particular period.

Usage

```r
PMT(rate, nper, pv, fv = 0, type = 0)
IPMT(rate, per, nper, pv, fv = 0, type = 0)
PPMT(rate, per, nper, pv, fv = 0, type = 0)
RBAL(rate, per, nper, pv, fv = 0, type = 0)
```
PMT

Arguments

rate specifies the interest rate.
per specifies the period of the payment to be applied to interest or to principal.
nper specifies the number of payment periods.
 pv specifies the present value or the lump-sum amount that a series of future payments is worth currently. pv can be 0 if a positive fv argument is included.
fv specifies the future value or a cash balance that you want to attain after the last payment is made. Default is 0.
type specifies the number 0 or 1 and indicates when payments are due. Default is 0.

Value

a numeric value

PoissonCI

Poisson Confidence Interval

Description

Computes the confidence intervals of a poisson distributed variable’s lambda. Several methods are implemented, see details.

Usage

PoissonCI(x, n = 1, conf.level = 0.95, sides = c("two.sided","left","right"), method = c("exact", "score", "wald", "byar"))

Arguments

x
number of events.
n
time base for event count.
conf.level
confidence level, defaults to 0.95.
sides
a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.
method
character string specifying which method to use: can be one out of "wald", "score", "exact" or "byar". Method can be abbreviated. See details. Defaults to "score".

Details

The Wald interval uses the asymptotic normality of the test statistic.

Byar’s method is quite a good approximation. Rothman and Boice (1979) mention that these limits were first proposed by Byar (unpublished).

Value

A vector with 3 elements for estimate, lower confidence intervall and upper for the upper one.

PolarGrid

Plot a Grid in Polar Coordinates

Description

PolarGrid adds a polar grid to an existing plot. The number of radial gridlines are set by ntheta and the tangential lines by nr. Labels for the angular grid and the radial axis can be provided.

Usage

PolarGrid(nr = NULL, ntheta = NULL, col = "lightgray", lty = "dotted", lwd = par("lwd"), rlabels = NULL, alabels = NULL, lblradians = FALSE, cex.lab = 1, las = 1, adj = NULL, dist = NULL)

Arguments

nr

number of circles. When NULL, as per default, the grid aligns with the tick marks on the corresponding default axis (i.e., tickmarks as computed by axTicks). When NA, no circular grid lines are drawn.

ntheta

number of radial grid lines. Defaults to 12 uniformly distributed between 0 and 2*pi (each pi/3).
col character or (integer) numeric; color of the grid lines.

lty character or (integer) numeric; line type of the grid lines.

lwd non-negative numeric giving line width of the grid lines.

rlabels the radius labels. Use NA if no labels should be to be added.

alabels the labels for the angles, they are printed on a circle outside the plot. Use NA for no angle labels.

lblradians logic, defines if angle labels will be in degrees (default) or in radians.

cex.lab the character extension for the labels.

las alignment of the labels, 1 means horizontal, 2 radial and 3 vertical.

adj adjustments for the labels. (Left: 0, Right: 1, Mid: 0.5) The default is 1 for the levels on the right side of the circle, 0 for labels on the left and 0.5 for labels exactly on north on south.

dist gives the radius for the labels, in user coordinates. Default is par("usr")[2] * 1.07.

PostHocTest  Post-Hoc Tests

Description

A convenience wrapper for computing post-hoc test after having calculated an ANOVA.
Usage

PostHocTest(x, ...)  
  
  ## S3 method for class 'aov'
  PostHocTest(x, which = NULL,
               method = c("hsd", "bonferroni", "lsd", "scheffe", "newmankeuls", "duncan"),
               conf.level = 0.95, ordered = FALSE, ...)
  
  ## S3 method for class 'table'
  PostHocTest(x, method = c("none", "fdr", "BH", "BY", "bonferroni",
                         "holm", "hochberg", "hommel"),
               conf.level = 0.95, ...)
  
  ## S3 method for class 'PostHocTest'
  print(x, digits =getOption("digits", 3), ...)
  
Arguments

x an aov object.

method one of "hsd", "bonf", "lsd", "scheffe", "newmankeuls", defining the method
         for the pairwise comparisons.
         For the post hoc test of tables the methods of p.adjust can be supplied. See the
detail there.

which a character vector listing terms in the fitted model for which the intervals should
        be calculated. Defaults to all the terms.

c.conf.level a numeric value between zero and one giving the family-wise confidence level
               to use. If this is set to NA, just a matrix with the p-values will be returned.

ordered a logical value indicating if the levels of the factor should be ordered
         according to increasing average in the sample before taking differences. If ordered is TRUE
         then the calculated differences in the means will all be positive. The significant
         differences will be those for which the lower end point is positive.
         This argument will be ignored if method is not either hsd or newmankeuls.

digits controls the number of fixed digits to print.

... further arguments, not used so far.

Details

The function is designed to consolidate a couple of post-hoc tests with the same interface for input
and output.

Choosing Tests

Different Post Hoc tests use different methods to control FW and PE. Some tests are very conser-
vative. Conservative tests go to great lengths to prevent the user from committing a Type I error.
They use more stringent criterion for determining significance. Many of these tests become more
and more stringent as the number of groups increases (directly limiting the FW and PE error rate).
Although these tests buy you protection against Type I error, it comes at a cost. As the tests become more stringent, you lose Power (1−B). More Liberal tests, buy you Power but the cost is an increased chance of Type I error. There is no set rule for determining which test to use, but different researchers have offered some guidelines for choosing. Mostly it is an issue of pragmatics and whether the number of comparisons exceeds K-1.

Fisher’s LSD
The Fisher LSD (Least Significant Different) sets Alpha Level per comparison. Alpha = .05 for every comparison. df = df error (i.e. df within). This test is the most liberal of all Post Hoc tests. The critical t for significance is unaffected by the number of groups. This test is appropriate when you have 3 means to compare. In general the alpha is held at .05 because of the criterion that you can’t look at LSD’s unless the Anova is significant. This test is generally not considered appropriate if you have more than 3 means unless there is reason to believe that there is no more than one true Null Hypothesis hidden in the means.

Dunn’s (Bonferroni)
Dunn’s t-test is sometimes referred to as the Bonferroni t because it used the Bonferroni PE correction procedure in determining the critical value for significance. In general, this test should be used when the number of comparisons you are making exceeds the number of degrees of freedom you have between groups (e.g. K-1). This test sets alpha per experiment; Alpha = (.05)/c for every comparison. df = df error (c = number of comparisons (K(K-1))/2). This test is extremely conservative and rapidly reduces power as the number of comparisons being made increase.

Newman-Keuls
Newman-Keuls is a step down procedure that is not as conservative as Dunn’s t test. First, the means of the groups are ordered (ascending or descending) and then the largest and smallest means are tested for significant differences. If those means are different, then test smallest with next largest, until you reach a test that is not significant. Once you reach that point then you can only test differences between means that exceed the difference between the means that were found to be non-significant. Newman-Keuls is perhaps one of the most common Post Hoc test, but it is a rather controversial test. The major problem with this test is that when there is more than one true Null Hypothesis in a set of means it will overestimate they FW error rate. In general we would use this when the number of comparisons we are making is larger than K-1 and we don’t want to be as conservative as the Dunn’s test is.

Tukey’s HSD
Tukey HSD (Honestly Significant Difference) is essentially like the Newman-Keul, but the tests between each mean are compared to the critical value that is set for the test of the means that are furthest apart (rmax e.g. if there are 5 means we use the critical value determined for the test of X1 and X5). This Method corrects for the problem found in the Newman-Keuls where the FW is inflated when there is more than one True Null Hypothesis in a set of means. It buys protection against Type I error, but again at the cost of Power. It tends to be the most common test and preferred test because it is very conservative with respect to Type I error when the Null hypothesis is true. In general, HSD is preferred when you will make all the possible comparisons between a large set of means (Six or more means).

Scheffe
The Scheffe Test is designed to protect against a Type I error when all possible complex and simple comparisons are made. That is we are not just looking the possible combinations of comparisons between pairs of means. We are also looking at the possible combinations of comparisons between groups of means. Thus Scheffe is the most conservative of all tests. Because this test does give us the
power.chisq.test

capacity to look at complex comparisons, it essentially uses the same statistic as the Linear Contrasts tests. However, Scheffe uses a different critical value (or at least it makes an adjustment to the critical value of F). This test has less power than the HSD when you are making Pairwise (simple) comparisons, but it has more power than HSD when you are making Complex comparisons. In general, only use this when you want to make many Post Hoc complex comparisons (e.g. more than K-1).

Tables
For tables pairwise chi-square test can be performed, either without correction or with correction for multiple testing following the logic in p.adjust.

Value
an object of type "PostHocTest", which will either be
A) a list of data.frames containing the mean difference, lower ci, upper ci and the p-value, if a conf.level was defined (something else than NA) or
B) a list of matrices with the p-values, if conf.level has been set to NA.

  conf.level=NA)

power.chisq.test

Description
Compute power of test or determine parameters to obtain target power (same as power.anova.test).
Usage

power.chisq.test(n = NULL, w = NULL, df = NULL, sig.level = 0.05, power = NULL)

Arguments

n  total number of observations.
w  effect size.
df  degree of freedom (depends on the chosen test).
sig.level  Significance level (Type I error probability).
power  Power of test (1 minus Type II error probability).

Details

Exactly one of the parameters w, n, power or sig.level must be passed as NULL, and this parameter is determined from the others. Note that the last one has non-NULL default, so NULL must be explicitly passed, if you want to compute it.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with 'method' and 'note' elements.

Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

---

**Description**

A couple of functions to get R-stuff into MS-Powerpoint.

*GetNewPP()* starts a new instance of PowerPoint and returns its handle. A new presentation with one empty slide will be created thereby. The handle is needed for addressing the presentation afterwards.

*GetCurrPP()* will look for a running PowerPoint instance and return its handle. NULL is returned if nothing's found. *PpAddSlide()* inserts a new slide into the active presentation.

*PpPlot()* inserts the active plot into PowerPoint. The image is transferred by saving the picture to a file in R and inserting the file in PowerPoint. The format of the plot can be selected, as well as crop options and the size factor for inserting.

*PpText()* inserts a new textbox with given text and box properties.

**Usage**

```r
GetNewPP(visible = TRUE, template = "Normal")
GetCurrPP()

PpAddSlide(pos = NULL, pp = DescToolsOptions("lastPP"))

PpPlot(type = "png", crop = c(0, 0, 0, 0), picscale = 100, x = 1, y = 1,
       height = NA, width = NA, res=200, dfact=1.6, pp = DescToolsOptions("lastPP"))

PpText(txt, x = 1, y = 1, height = 50, width = 100, fontname = "Calibri", fontsize = 18,
       bold = FALSE, italic = FALSE, col = "black", bg = "white",
       hasFrame = TRUE, pp = DescToolsOptions("lastPP"))
```

**Arguments**

- **visible** logical, should PowerPoint made visible by *GetNewPP()*? Defaults to TRUE.
- **template** the name of the template to be used for the new presentation.
- **pos** position of the new inserted slide within the presentation.
- **type** the format for the picture file, default is "png".
- **crop** crop options for the picture, defined by a 4-elements-vector. The first element is the bottom side, the second the left and so on.
- **picscale** scale factor of the picture in percent, default ist 100.
- **x, y** left/upper xy-coordinate for the plot or for the textbox.
- **height** height in cm, this overrides the picscale if both are given.
width    width in cm, this overrides the picscale if both are given.
res      resolution for the png file, defaults to 200.
dfact    the size factor for the graphic.
txt      text to be placed in the textbox
fontname used font for textbox
fontsize used fontsize for textbox
bold     logic. Text is set bold if this is set to TRUE (default is FALSE).
italic   logic. Text is set italic if this is to TRUE (default is FALSE).
col      font color, defaults to "black".
bg        background color for textbox defaults to "white".
hasFrame logical. Defines if a textbox is to be framed. Default is TRUE.
pp        the pointer to a PowerPoint instance, can be a new one, created by GetNewPP() or the last created by DescToolsOptions("lastPP") (default).

Details
See PowerPoint-objectmodel for further informations.

Value
The functions return the pointer to the created object.

**pRevGumbel**  
"Reverse" Gumbel Distribution Functions

**Description**

Density, distribution function, quantile function and random generation for the "Reverse" Gumbel distribution with parameters location and scale.

**Usage**

```
dRevGumbel (x, location = 0, scale = 1)
pRevGumbel (q, location = 0, scale = 1)
qRevGumbel (p, location = 0, scale = 1)
rRevGumbel (n, location = 0, scale = 1)
qRevGumbelExp(p)
```

**Arguments**

- `x, q`
  
  numeric vector of abscissa (or quantile) values at which to evaluate the density or distribution function.
Primes

p numeric vector of probabilities at which to evaluate the quantile function.
location location of the distribution
scale scale (> 0) of the distribution.
n number of random variates, i.e., length of resulting vector of rRevGumbel().

Value

a numeric vector, of the same length as x, q, or p for the first three functions, and of length n for rRevGumbel().

Author(s)

Werner Stahel; partly inspired by package VGAM. Martin Maechler for numeric cosmetic.

See Also

abline(h=0:1, v = 0, lty=3, col = "gray30"
curve(dRevGumbel(x, scale= 1/2), n=1001, add=TRUE,
col = (col.d <- adjustcolor(2, 0.5)), lwd=3)
legend("left", c("cdf","pdf"), col=c("black", col.d), lwd=2:3, bty="n")

med <- qRevGumbel(0.5, scale=1/2)
cat("The median is:", format(med,"
")

Primes Find All Primes Less Than n

Description

Find all prime numbers aka ‘primes’ less than n.
Uses an obvious sieve method and some care, working with logical and integers to be quite fast.

Usage

Primes(n)

Arguments

n a (typically positive integer) number.

Details

As the function only uses max(n), n can also be a vector of numbers.
Value
numeric vector of all prime numbers \( \leq n \).

Note
This function was previously published in the package sfsmisc as primes and has been integrated here without logical changes.

Author(s)
Bill Venables (\( \leq n \)); Martin Maechler gained another 40% speed, working with logicals and integers.

See Also
Factorize, GCD, LCM, IsPrime

Examples
```r
(p1 <- Primes(100))
system.time(p1k <- Primes(1000)) # still lightning ..
stopifnot(length(p1k) == 168)
```

PseudoR2  Pseudo R2 Statistics

Description
Although there's no commonly accepted agreement on how to assess the fit of a logistic regression, there are some approaches. The goodness of fit of the logistic regression model can be expressed by some variants of pseudo R squared statistics, most of which being based on the deviance of the model.

Usage
PseudoR2(x, which = NULL)

Arguments
- **x** the glm, polr or multinom model object to be evaluated.
Details

Cox and Snell’s $R^2$ is based on the log likelihood for the model compared to the log likelihood for a baseline model. However, with categorical outcomes, it has a theoretical maximum value of less than 1, even for a "perfect" model.

Nagelkerke’s $R^2$ (also sometimes called Cragg-Uhler) is an adjusted version of the Cox and Snell’s $R^2$ that adjusts the scale of the statistic to cover the full range from 0 to 1.

McFadden’s $R^2$ is another version, based on the log-likelihood kernels for the intercept-only model and the full estimated model.

Veall and Zimmermann concluded that from a set of six widely used measures the measure suggested by McKelvey and Zavoina had the closest correspondance to ordinary least square R2. The Aldrich-Nelson pseudo-R2 with the Veall-Zimmermann correction is the best approximation of the McKelvey-Zavoina pseudo-R2. Efron, Aldrich-Nelson, McFadden and Nagelkerke approaches severely underestimate the "true R2".

Value

the value of the specific statistic. AIC, LogLik, LogLikNull and G2 will only be reported with option "all".

McFadden McFadden pseudo-$R^2$
McFaddenAdj McFadden adjusted pseudo-$R^2$
CoxSnell Cox and Snell pseudo-$R^2$ (also known as ML pseudo-$R^2$)
Nagelkerke Nagelkerke pseudo$R^2$ (also known as CraggUhler $R^2$)
AldrichNelson AldrichNelson pseudo-$R^2$
VeallZimmermann VeallZimmermann pseudo-$R^2$
McKelveyZavoina McKelvey and Zavoina pseudo-$R^2$
Efron Efron pseudo-$R^2$
Tjur Tjur’s pseudo-$R^2$
AIC Akaike’s information criterion
LogLik log-Likelihood for the fitted model (by maximum likelihood)
LogLikNull log-Likelihood for the null model. The null model will include the offset, and an intercept if there is one in the model.
G2 differenz of the null deviance - model deviance

Author(s)

Andri Signorell <andri@signorell.net>
PtInPoly

Description
PtInPoly works out, whether XY-points lie within the boundaries of a given polygon.

Note: Points that lie on the boundaries of the polygon or vertices are assumed to lie within the polygon.

Usage
PtInPoly(pnts, poly.pnts)

References

See Also
logLik, AIC, BIC

Examples
r.glm <- glm(Survived ~ ., data=Untable(Titanic), family=binomial)
PseudoR2(r.glm)
PseudoR2(r.glm, c("McFadden", "Nagel"))
Arguments

- **pnts**: a 2-column matrix or dataframe defining locations of the points of interest
- **poly.pnts**: a 2-column matrix or dataframe defining the locations of vertices of the polygon of interest

Details

The algorithm implements a sum of the angles made between the test point and each pair of points making up the polygon. The point is interior if the sum is 2\pi, otherwise, the point is exterior if the sum is 0. This works for simple and complex polygons (with holes) given that the hole is defined with a path made up of edges into and out of the hole.

This sum of angles is not able to consistently assign points that fall on vertices or on the boundary of the polygon. The algorithm defined here assumes that points falling on a boundary or polygon vertex are part of the polygon.

Value

A 3-column dataframe where the first 2 columns are the original locations of the points. The third column (names `pip`) is a vector of binary values where 0 represents points not with the polygon and 1 within the polygon.

Author(s)

Jeremy VanDerWal <jjvanderwal@gmail.com>

Examples

```r
# define the points and polygon
pnts <- expand.grid(x=seq(1,6,0.1), y=seq(1,6,0.1))
polypnts <- cbind(x=c(2,3,3.5,3.5,3,4,5,4,5,5,4,3,3,2,1,1,1,1,2),
y=c(1,2,2.5,2,1,2,3,4,5,4,5,4,3,3,4,5,4,3,2,2))

# plot the polygon and all points to be checked
plot(rbind(polypnts, pnts))
polygon(polypnts, col=’#99999990’)

# create check which points fall within the polygon
out <- PtInPoly(pnts, polypnts)
head(out)

# identify points not in the polygon with an X
points(out[which(out$pip==0), 1:2], pch=’X’)
```
Quantile

Weighted Quantiles

Description
Compute weighted quantiles (Eurostat definition).

Usage
Quantile(x, weights = NULL, probs = seq(0, 1, 0.25), na.rm = FALSE,
       names = TRUE, type = 7)

Arguments
- x: a numeric vector.
- weights: an optional numeric vector giving the sample weights.
- probs: numeric vector of probabilities with values in [0, 1].
- na.rm: a logical indicating whether missing values in x should be omitted.
- names: logical; if true, the result has a names attribute. Set to FALSE for speedup with many probs.
- type: an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.

Details
The implementation strictly follows the Eurostat definition.

Value
A numeric vector containing the weighted quantiles of values in x at probabilities probs is returned. Unlike quantile, this returns an unnamed vector.

Author(s)
Andreas Alfons and Matthias Templ

References

See Also
Median

Examples
Quantile(d.pizza$temperature, rep(c(1:3), length.out=nrow(d.pizza)))
Lagged Quotients

Description

Returns suitably lagged and iterated quotients

Usage

Quot(x, lag = 1, quotients = 1, ...)

Arguments

x  
a numeric vector or matrix containing the values to be used for calculating the quotients.

lag  
an integer indicating which lag to use.

quotients  
an integer indicating the order of the quotient.

...  
further arguments to be passed to or from methods.

Details

NA's propagate.

Value

If x is a vector of length n and quotients = 1, then the computed result is equal to the successive quotients x[(1+lag):n] - x[1:(n-lag)].

If quotients is larger than one this algorithm is applied recursively to x. Note that the returned value is a vector which is shorter than x.

If x is a matrix then the division operations are carried out on each column separately.

x <- cumprod(cumprod(1:10))
Quot(x, lag = 2)
Quot(x, quotients = 2)
Range

(Robust) Range

Description

 Determines the range of the data, which can possibly be trimmed before calculating the extreme values. The robust range version is calculated on the basis of the trimmed mean and variance (see Details).

Usage

Range(x, trim = NULL, robust = FALSE, na.rm = FALSE, ...)

Arguments

x a numeric vector.
trim the fraction (0 to 0.5) of observations to be trimmed from each end of x before the mean is computed. Values of trim outside that range are taken as the nearest endpoint. Default is 0 for robust=FALSE and 0.2 for robust=TRUE
robust logical, determining whether the robust or the conventional range should be returned.
na.rm a logical value indicating whether NA values should be stripped before the computation proceeds.
... the dots are sent to RobRange and can be used to set fac (See details).

Details

The R base function range returns the minimum and maximum value of a numeric object. Here we return the span of a (possibly trimmed) numeric vector, say the difference of maximum and minimum value.

If robust is set to TRUE the function determines the trimmed mean m and then the "upper trimmed mean" s of absolute deviations from m, multiplied by fac (fac is 3 by default). The robust minimum is then defined as m-fac*s or min(x), whichever is larger, and similarly for the maximum.

Value

If trim is zero (the default), the arithmetic mean of the values in x is computed, as a numeric or complex vector of length one. If x is not logical (coerced to numeric), numeric (including integer) or complex, NA_real_ is returned, with a warning.

If trim is non-zero, a symmetrically trimmed mean is computed with a fraction of trim observations deleted from each end before the mean is computed.

`range, min, max`

Examples

```r
x <- c(0:10, 50)
xm <- Range(x)
c(xm, Range(x, trim = 0.10))

x <- c(rnorm(20), rnorm(3, 5, 20))
Range(x, robust=TRUE)

# compared to
Range(x)
```

---

**Recode**

**Recode a Factor**

Description

Combining or rearranging a factor can be tedious if it has many levels. `Recode` supports this step by accepting a direct definition of new levels by enumerating old levelnames as argument and adding an "elselevel" option. If new levels are given as integer values they will be translated in the according levels.

Usage

```r
Recode(x, ..., elselevel = NA, use.empty = FALSE, num = FALSE)
```

Arguments

- `x`: the factor whose levels are to be altered.
- `...`: the old levels (combined by `c()` if there are several) named with the new level:
  ```r
  newlevel_a=c("old_a","old_b"),
  newlevel_b=c("old_c","old_d")
  ```
  See examples.
- `elselevel`: the value for levels, which are not matched by newlevel list. If this is set to `NULL`, the elselevels will be left unchanged. If set to `NA` (default) non matched levels will be set to `NA`.
- `use.empty`: logical. Defines how a new level, which can’t be found in `x`, should be handled. Should it be left in the level’s list or be dropped? The default is `FALSE`, which drops empty levels.
- `num`: logical. If set to `TRUE` the result will be numeric.

Value

the factor having the new levels applied.
Recode

Andri Signorell <andri@signorell.net>

See Also

factor, levels
There's another solution in the package car.

Examples

```r
set.seed(1984)
x <- factor(sample(1:15, 20, replace=TRUE))
levels(x) <- paste("old", levels(x), sep="_")

y <- Recode(x,
  "new_1" = c("old_1","old_4","old_5"),
  "new_2" = c("old_6","old_10","old_11"),
  "new_3" = c("old_12","old_13"),
  elselevel = "other")
data.frame(x=x, y=y)

x <- factor(letters[1:6])
z1 <- Recode(x, AB=c("a","b"), CD=c("c","d"), elselevel="none of these")
z2 <- Recode(x, AB=c("a","b"), CD=c("c","d"), elselevel=NA)
z3 <- Recode(x, AB=c("a","b"), CD=c("c","d"), elselevel=NULL)
z4 <- Recode(x, AB=c("a","b"), GH=c("g","h"), elselevel=NA, use.empty=TRUE)
z5 <- Recode(x, AB=c("a","b"), GH=c("g","h"), elselevel=NA, use.empty=FALSE)
data.frame(z1, z2, z3, z4, z5)
lapply(data.frame(z1, z2, z3, z4, z5), levels)

# empty level GH exists in z4...
table(z4, useNA="ifany")
# and is dropped in z5
table(z5, useNA="ifany")

# use integers to define the groups to collapse
set.seed(1972)
(likert <- factor(sample(1:10, size=15, replace=TRUE),
  levels=1:10, labels=gettextf("(%s)", 1:10)))
Recode(likert, det=1:6, pas=7:8, pro=9:10)

# or directly turned to numeric
Recode(likert, "1"=1:6, "2"=7:8, "5"=9:10, num=TRUE)
```
Recycle

Recyle a List of Elements

Description

This function recycles all supplied elements to the maximal dimension.

Usage

Recycle(...)

Arguments

... a number of vectors of elements.

Value

a list of the supplied elements
attr("maxdim") contains the maximal dimension of the recycled list

Author(s)

Andri Signorell <andri@signorell.net>

See Also

rep, replicate

Examples

Recycle(x=1:5, y=1, s=letters[1:2])

z <- Recycle(x=letters[1:5], n=2:3, sep=c("-", " "))
sapply(1:attr(z, "maxdim"), function(i) paste(rep(z$x[i], times=z$n[i]), collapse=z$sep[i]))

RelRisk

Relative Risk

Description

Computes the relative risk and its confidence intervals. Confidence intervals are calculated using normal approximation ("wald"), ("score") or by using odds ratio ("use.or")

Usage

RelRisk(x, y = NULL, conf.level = NA, method = c("score", "wald", "use.or"), delta = 0.5, ...)

RelRisk

Relative Risk

Description

Computes the relative risk and its confidence intervals. Confidence intervals are calculated using normal approximation ("wald"), ("score") or by using odds ratio ("use.or")

Usage

RelRisk(x, y = NULL, conf.level = NA, method = c("score", "wald", "use.or"), delta = 0.5, ...)
Arguments

x  a numeric vector or a 2x2 numeric matrix, resp. table.
y NULL (default) or a vector with compatible dimensions to x. If y is provided, table(x,y,...) will be calculated.
conf.level confidence level. Default is NA, meaning no confidence intervals will be reported.
method method for calculating odds ratio and confidence interval. Can be one out of "score", "wald", "use.or". Default is "score".
delta small constant to be added to the numerator for calculating the log risk ratio (Wald method). Usual choice is 0.5 although there does not seem to be any theory behind this. (Dewey, M. 2006)
... further arguments are passed to the function table, allowing i.e. to set useNA.

Details

This function expects the following table structure:

<table>
<thead>
<tr>
<th></th>
<th>disease=0</th>
<th>disease=1</th>
</tr>
</thead>
<tbody>
<tr>
<td>exposed=0</td>
<td>n00</td>
<td>n01</td>
</tr>
<tr>
<td>exposed=1</td>
<td>n10</td>
<td>n11</td>
</tr>
</tbody>
</table>

If the table to be provided is not in the preferred form, use the function Rev() to "reverse" the table rows, -columns, or both.

Value

If conf.level is not NA then the result will be a vector with 3 elements for estimate, lower confidence intervall and upper for the upper one. Else the relative risk will be reported as a single value.

Author(s)

Andri Signorell <andri@signorell.net>, based on code of Yongyi Min and Michael Dewey

**Rename**

*Change Names of a Named Object*

Description

Rename changes the names of a named object.

Usage

\[
\text{Rename}(x, \ldots, \text{gsub}=\text{FALSE}, \text{fixed}=\text{TRUE}, \text{warn}=\text{TRUE})
\]

Arguments

- **x**
  Any named object
- **\ldots**
  A sequence of named arguments, all of type character
- **gsub**
  a logical value; if TRUE, \text{gsub} is used to change the row and column labels of the resulting table. That is, instead of substituting whole names, substrings of the names of the object can changed.
- **fixed**
  a logical value, passed to \text{gsub}. If TRUE, substitutions are by fixed strings and not by regular expressions.
- **warn**
  a logical value; should a warning be issued if those names to change are not found?

Details

This function changes the names of \(x\) according to the remaining arguments. If \text{gsub} is \text{FALSE}, argument tags are the old names, the values are the new names. If \text{gsub} is \text{TRUE}, arguments are substrings of the names that are substituted by the argument values.

Value

The object \(x\) with new names defined by the \ldots arguments.

Note

This function was previously published in the package **memisc** as \text{rename} and has been integrated here without logical changes.

reorder.factor

Reorder the Levels of a Factor

Description
Reorder the levels of a factor

Usage
```r
## S3 method for class 'factor'
reorder(x, X, FUN, ..., 
    order = is.ordered(x), new.order, sort = SortMixed)
```

Arguments
- `x` factor
- `X` auxillary data vector
- `FUN` function to be applied to subsets of `X` determined by `x`, to determine factor order
- `...` optional parameters to `FUN`
- `order` logical value indicating whether the returned object should be an ordered factor
- `new.order` a vector of indexes or a vector of label names giving the order of the new factor levels
- `sort` function to use to sort the factor level names, used only when `new.order` is missing
Details

This function changes the order of the levels of a factor. It can do so via three different mechanisms, depending on whether, X and FUN, new.order or sort are provided.

If X and FUN are provided: The data in X is grouped by the levels of x and FUNC is applied. The groups are then sorted by this value, and the resulting order is used for the new factor level names.

If new.order is provided: For a numeric vector, the new factor level names are constructed by reordering the factor levels according to the numeric values. For vectors, new.order gives the list of new factor level names. In either case levels omitted from new.order will become missing (NA) values.

If sort is provided (as it is by default): The new factor level names are generated by applying the supplied function to the existing factor level names. With sort=mixedsort the factor levels are sorted so that combined numeric and character strings are sorted in according to character rules on the character sections (including ignoring case), and the numeric rules for the numeric sections. See mixedsort for details.

Value

A new factor with reordered levels

# drop out the '300 MG' level
trt6 <- reorder(trt, new.order=c("PLACEBO", "600 MG", "1200 MG"))
summary(trt6)

---

**Rev**

*Reverse Elements of a Vector or the Rows/Columns of Matrices, Tables or Data.frames*

**Description**

Rev provides a reversed version of its argument. It wraps the base function `rev` and provides an additional method for matrices and higher dimensional tables, such as to reverse the order of rows and columns.

**Usage**

Rev(x, ...)

## S3 method for class 'matrix'
Rev(x, margin, ...)

## S3 method for class 'table'
Rev(x, margin, ...)

## S3 method for class 'data.frame'
Rev(x, margin, ...)

**Arguments**

x  
a vector, a matrix or a higher dimensional table to be reversed.

margin  
vector of dimensions which to be reversed (1 for rows, 2 for columns, etc.).

...  
the dots are passed to the matrix, resp. table interface.

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

`rev`, `order`, `sort`, `seq`
Examples

```
tab <- matrix( c( 1, 11, 111,
                2, 22, 222,
                3, 33, 333), byrow=TRUE, nrow=3)

Rev(tab, margin=1)
Rev(tab, margin=2)

# reverse both dimensions
Rev(tab, margin=c(1,2))
```

---

RevWeibull  

**The Reverse Weibull Distribution**

Description

Density function, distribution function, quantile function and random generation for the reverse (or negative) Weibull distribution with location, scale and shape parameters.

Usage

```
dRevWeibull(x, loc=0, scale=1, shape=1, log = FALSE)
pRevWeibull(q, loc=0, scale=1, shape=1, lower.tail = TRUE)
qRevWeibull(p, loc=0, scale=1, shape=1, lower.tail = TRUE)
rRevWeibull(n, loc=0, scale=1, shape=1)

dNegWeibull(x, loc=0, scale=1, shape=1, log = FALSE)
pNegWeibull(q, loc=0, scale=1, shape=1, lower.tail = TRUE)
qNegWeibull(p, loc=0, scale=1, shape=1, lower.tail = TRUE)
rNegWeibull(n, loc=0, scale=1, shape=1)
```

Arguments

- `x, q` Vector of quantiles.
- `p` Vector of probabilities.
- `n` Number of observations.
- `loc, scale, shape` Location, scale and shape parameters (can be given as vectors).
- `log` Logical; if TRUE, the log density is returned.
- `lower.tail` Logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \)

Details

The reverse (or negative) Weibull distribution function with parameters \( loc = a \), \( scale = b \) and \( shape = s \) is

\[
G(z) = \exp \left\{- \left[ \frac{z-a}{b} \right]^s \right\}
\]

for \( z < a \) and one otherwise, where \( b > 0 \) and \( s > 0 \).
Value

dRevWeibull and dNegWeibull give the density function, pRevWeibull and pNegWeibull give the
distribution function, qRevWeibull and qNegWeibull give the quantile function, rRevWeibull and
rNegWeibull generate random deviates.

Note

Within extreme value theory the reverse Weibull distribution (also known as the negative Weibull
distribution) is often referred to as the Weibull distribution. We make a distinction to avoid confu-
sion with the three-parameter distribution used in survival analysis, which is related by a change of
sign to the distribution given above.

## [1] 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9

Description

Converting a RGB-color to a named R-Color means looking for a color in the R-palette, which is
nearest to the given RGB-color. This function uses the minimum of squared distance ("euclidean")
or the minimum absolute distance ("manhattan") as proximity measure.
RgbToLong() converts a RGB-color to a long integer in numeric format. LongToRGB() does it the
other way round.

Usage

RgbToCol(col, method = "rgb", metric = "euclidean")

RgbToLong(col)
LongToRgb(col)
Arguments

- **col**: the color in rgb code, say a matrix with the red, green and blue code in the rows.
- **method**: character string specifying the color space to be used. Can be "rgb" (default) or "hsv".
- **metric**: character string specifying the metric to be used for calculating distances between the colors. Available options are "euclidean" (default) and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.

Details

It may not be clear from the start which method, rgb or hsv, yield the more natural results. Trying and comparing is a recommended strategy. Moreover the shortest numerical distance will not always be the best choice, when comparing the colours visually.

Value

the name of the nearest found R color.

Author(s)

Andri Signorell <andri@signorell.net>

```

### RndPairs

*Create Pairs of Correlated Random Numbers*

Description

Create pairs of correlated random numbers.

Usage

```r
RndPairs(n, r, rdist1 = rnorm(n = n, mean = 0, sd = 1),
         rdist2 = rnorm(n = n, mean = 0, sd = 1))
RndWord(size, length, x = LETTERS, replace = TRUE, prob = NULL)
```
### Arguments

- **n**: number of pairs. If length(n) > 1, the length is taken to be the number required.
- **r**: the correlation between the two sets.
- **rdist1, rdist2**: the distribution of the random vector X1 and X2. Default is standard normal distribution.
- **size**: a non-negative integer giving the number of artificial words to build.
- **length**: a non-negative integer giving the length of the words.
- **x**: elements to choose from.
- **replace**: Should sampling be with replacement?
- **prob**: a vector of probability weights for obtaining the elements of the vector being sampled.

### Value

A data.frame with 2 columns, X1 and X2 containing the random numbers.

### Author(s)

Andri Signorell <andri@signorell.net>

### See Also

- `runif`, `rnorm`, `Random` and friends

### Examples

```r
# produce 100 pairs of a normal distributed random number with a correlation of 0.7
d.frm <- RndPairs(n=100, r=0.7)

plot(d.frm)
lines(lm(X2 ~ X1,d.frm))

# change the distribution
d.frm <- RndPairs(n=100, r=0.7, rdist2 = rlnorm(n = 100, meanlog = 1, sdlog = .8))
d.frm <- RndPairs(n=100, r=0.7, rdist2 = runif(n = 100, -1, 4))

x <- StrCap(sapply(sample(3:15, 10), function(i) RndWord(1, i, x=letters)))

# produce some artificial words with defined probabilities for the letters
p <- c(6.51,1.89,3.06,5.08,17.4,1.66,3.01,4.76,7.55,0.27,1.21,3.44,2.53,9.78,2.51,0.79,0.02,7.27,6.15,4.35,0.67,1.89,0.03,0.04,1.13)
sapply(sample(3:15, 10), function(i) RndWord(1, i, x=letters, prob=p))
```
RobScale

Robust Scaling With Median and Mad

Description

RobScale is a wrapper function for robust standardization, using median and mad instead of mean and sd.

Usage

RobScale(x, center = TRUE, scale = TRUE)

Arguments

x
a numeric matrix(like object).

center
a logical value defining whether x should be centered by the median. Centering is done by subtracting the column medians (omitting NAs) of x from their corresponding columns. If center is FALSE, no centering is done.

scale
a logical value defining whether x should be scaled by the mad. Scaling is done by dividing the (centered) columns of x by their mad. If scale is FALSE, no scaling is done.

Value

the centered, scaled matrix. The numeric centering and scalings used (if any) are returned as attributes "scaled:center" and "scaled:scale"

Author(s)

Andri Signorell <andri@signorell.net>

See Also

scale, sweep

Examples

x <- d.pizza$temperature
plot(x=seq_along(x), y=RobScale(x), xlim=c(0,100))

Convert Roman Numerals to Integers

Description
Convert roman numerals to integers

Usage
RomanToInt(x)

Arguments
x character vector containing roman numerals

Details
This function will convert roman numerals to integers without the upper bound imposed by R (3899), ignoring case.

Value
A integer vector with the same length as roman. Character strings which are not valid roman numerals will be converted to NA.

Author(s)
Gregory R. Warnes <greg@warnes.net>

as.roman

Examples
RomanToInt( c('I', 'V', 'X', 'C', 'L', 'D', 'M') )

# works regardless of case
RomanToInt( 'MMXVI' )
RomanToInt( 'mmxvi' )

# works beyond R's limit of 3899
val.3899 <- 'MMMDCXXCIX'
val.3900 <- 'MMMCM'
val.4000 <- 'MMMM'
as.numeric(as.roman( val.3899 ))
as.numeric(as.roman( val.3900 ))
as.numeric(as.roman( val.4000 ))
Description

Rotate a geometric structure by an angle theta around a centerpoint xy.

Usage

Rotate(x, y = NULL, mx = NULL, my = NULL, theta = pi/3, asp = 1)

Arguments

- x, y: vectors containing the coordinates of the vertices of the polygon, which has to be rotated. The coordinates can be passed in a plotting structure (a list with x and y components), a two-column matrix, .... See `xy.coords`.
- mx, my: xy-coordinates of the center of the rotation. If left to NULL, the centroid of the structure will be used.
- theta: angle of the rotation
- asp: the aspect ratio for the rotation. Helpful for rotate structures along an ellipse.

Value

The function invisibly returns a list of the coordinates for the rotated shape(s).

Author(s)

Andri Signorell <andri@signorell.net>

See Also

polygon, DrawRegPolygon, DrawEllipse, DrawArc

Examples

# let's have a triangle

# and rotate
sapply( (0:3) * pi/6, function(theta) {
  xy <- Rotate( x=x, theta=theta )
polygon(xy, col=SetAlpha("blue", 0.2))}
RoundTo

) )
abline(v=0, h=0)

<table>
<thead>
<tr>
<th>RoundTo</th>
<th>Round to Multiple</th>
</tr>
</thead>
</table>

Description
Returns a number rounded to the nearest specified multiple.

Usage
RoundTo(x, multiple = 1, FUN = round)

Arguments
- x: numeric. The value to round.
- multiple: numeric. The multiple to which the number is to be rounded. Default is 1.
- FUN: the rounding function as character or as expression. Can be one out of trunc, ceiling, round (default) or floor.

Details
There are several functions to convert to integers. `round` rounds to the nearest integer or to any number of digits. Using a negative number rounds to a power of ten, so that `round(x,-3)` rounds to thousands. Each of `trunc`, `floor` and `ceiling` round in a fixed direction, towards zero, down and up respectively. `round` is documented to round to even, so `round(2.5)` is 2.

RoundTo uses `round(x/multiple)*multiple` to get the result. So if `x` is equally close to two multiples, the multiple with the smaller absolute value will be returned when `round(x/multiple)` is even (and the greater when it’s odd).

If FUN is set to ceiling it will always round up, and if set to floor it will always round down. See examples for comparison).

Value
the rounded value

Author(s)
Andri Signorell <andri@signorell.net>

See Also
`round, trunc, ceiling, floor`
Examples

RoundTo(10, 3)  # Rounds 10 to a nearest multiple of 3 (9)
RoundTo(-10, -3)  # Rounds -10 to a nearest multiple of -3 (-9)

RoundTo(1.3, 0.2)  # Rounds 1.3 to a nearest multiple of 0.2 (1.2)
RoundTo(-1.3, 0.2)  # Rounds -1.3 to a nearest multiple of 0.2 (-1.2)
RoundTo(5, -2)  # Returns an error, because -2 and 5 have different signs

# Round down
RoundTo(c(1,-1) * 1.2335, 0.05, floor)
RoundTo(c(1,-1) * 1233.5, 100, floor)

# Round up
RoundTo(c(1,-1) * 1.2335, 0.05, ceiling)
RoundTo(c(1,-1) * 1233.5, 100, ceiling)

# Round towards zero
RoundTo(c(1,-1) * 1.2335, 0.05, trunc)
RoundTo(c(1,-1) * 1233.5, 100, trunc)

x <- c(-1.5,-1.3, 1.3, 1.5)
cbind(x = x,
      round = RoundTo(x, 0.2, FUN=round),
      trunc = RoundTo(x, 0.2, FUN=trunc),
      ceiling = RoundTo(x, 0.2, FUN=ceiling),
      floor = RoundTo(x, 0.2, FUN=floor))

x <- -10:10
cbind(x = x,
      round = RoundTo(x, 2, FUN=round),
      trunc = RoundTo(x, 2, FUN=trunc),
      ceiling = RoundTo(x, 2, FUN=ceiling),
      floor = RoundTo(x, 2, FUN=floor))

RSessionAlive

How Long Has the RSession Been Running?

Description

RSessionAlive() returns the time the R session has been running in hours. The function uses powershell in Windows and is thus restricted to run in windows only. RTempdirAlive() does the same for temporary directories, but runs on all systems.

Usage

RSessionAlive()
RTempdirAlive()
Value
time in hours

Sys.getenv

---

**RunsTest**

*Runs Test for Randomness*

**Description**

Performs a test whether the elements of x are serially independent - say, whether they occur in a random order - by counting how many runs there are above and below a threshold. If y is supplied a two sample Wald-Wolfowitz-Test testing the equality of two distributions against general alternatives will be computed.

**Usage**

```
RunsTest(x, ...)
```

## Default S3 method:
```
RunsTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
    exact = NULL, correct = TRUE, na.rm = FALSE, ...)
```

## S3 method for class 'formula'
```
RunsTest(formula, data, subset, na.action, ...)
```

**Arguments**

- `x`: a dichotomous vector of data values or a (non-empty) numeric vector of data values.
- `y`: an optional (non-empty) numeric vector of data values.
- `formula`: a formula of the form `lhs ~ rhs` where `lhs` gives the data values and `rhs` the corresponding groups.
- `data`: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset`: an optional vector specifying a subset of observations to be used.
- `na.action`: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`. 
alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "less" or "greater".

exact a logical indicating whether an exact p-value should be computed. By default exact values will be calculated for small vectors with a total length <= 30 and the normal approximation for longer ones.

correct a logical indicating whether to apply continuity correction when computing the test statistic. Default is TRUE. Ignored if exact is set to TRUE. See details.

na.rm defines if NAs should be omitted. Default is FALSE.

... further arguments to be passed to or from methods.

Details

The runs test for randomness is used to test the hypothesis that a series of numbers is random. The 2-sample test is known as the Wald-Wolfowitz test.

For a categorical variable, the number of runs correspond to the number of times the category changes, that is, where \( x_i \) belongs to one category and \( x_{i+1} \) belongs to the other. The number of runs is the number of sign changes plus one.

For a numeric variable \( x \) containing more than two values, a run is a set of sequential values that are either all above or below a specified cutpoint, typically the median. This is not necessarily the best choice. If another threshold should be used use a code like: \( \text{RunsTest}(x > \text{mean}(x)) \).

The exact distribution of runs and the p-value based on it are described in the manual of SPSS "Exact tests" [link](http://www.sussex.ac.uk/its/pdfs/SPSS_Exact_Tests_21.pdf).

The normal approximation of the runs test is calculated with the expected number of runs under the null

\[
\mu_r = \frac{2n_0n_1}{n_0 + n_1} + 1
\]

and its variance

\[
\sigma_r^2 = \frac{2n_0n_1(2n_0n_1 - n_0 - n_1)}{(n_0 + n_1)^2 \cdot (n_0 + n_1 - 1)}
\]

as

\[
\hat{z} = \frac{r - \mu_r + c}{\sigma_r}
\]

where \( n_0, n_1 \) the number of values below/above the threshold and \( r \) the number of runs.

Setting the continuity correction correct = TRUE will yield the normal approximation as SAS (and SPSS if \( n < 50 \)) does it, see [link](http://support.sas.com/kb/33/092.html). The \( c \) is set to \( c = 0.5 \) if \( r < \frac{2n_0n_1}{n_0 + n_1} + 1 \) and to \( c = -0.5 \) if \( r > \frac{2n_0n_1}{n_0 + n_1} + 1 \).

Wald-Wolfowitz with Ties. Ideally there should be no ties in the data used for the Wald-Wolfowitz test. In practice there is no problem with ties within a group, but if ties occur between members of the different groups then there is no unique sequence of observations. For example the data sets A: 10,14,17,19,34 and B: 12,13,17,19,22 can give four possible sequences, with two possible values for \( r \) (7 or 9). The "solution" to this is to list every possible combination, and calculate the test statistic for each one. If all test statistics are significant at the chosen level, then one can reject the null hypothesis. If only some are significant, then Siegel (1956) suggests that the average of the P-values
is taken. Help for finding all permutations of ties can be found at: https://stackoverflow.com/questions/47565066/all-possible-permutations-in-factor-variable-when-ties-exist-in-r

However this solutions seems quite coarse and in general, the test should not be used if there are more than one or two ties. We have better tests to distinguish between two samples!

Value

A list with the following components.

- statistic: \( z \), the value of the standardized runs statistic, if not exact p-values are computed.
- parameter: the number of runs, the total number of zeros \( m \) and ones \( n \)
- p.value: the p-value for the test.
- data.name: a character string giving the names of the data.
- alternative: a character string describing the alternative hypothesis.

Run Length Encoding rle

Examples

```r
# x will be coerced to a dichotomous variable
RunsTest(x)

x <- c(13, 3, 14, 14, 1, 14, 3, 8, 14, 17, 9, 14, 13, 2, 16, 1, 3, 12, 13, 14)
RunsTest(x)
# this will be treated as
RunsTest(x > median(x))

plot((x < median(x)) - 0.5, type="s", ylim=c(-1,1))
abline(h=0)

set.seed(123)
x <- sample(0:1, size=100, replace=TRUE)
```
Sample

Random Samples and Permutations

Description

Sample takes a sample of the specified size from the elements of x using either with or without replacement. The function does the same as the base::sample() and offers additionally an interface for data frames.

Usage

Sample(x, size, replace = FALSE, prob = NULL)

Arguments

x
either a vector of one or more elements from which to choose, or a positive integer.

size
a positive number, the number of items to choose from.

replace
a non-negative integer giving the number of items to choose.

prob
should sampling be with replacement?

Value

sampled elements in the same structure as x
SampleTwins

Author(s)

Andri Signorell <andri@signorell.net>

See Also

sample

Examples

sample(d.pizza, size=5)

Description

Draw a twin sample out of a population for a given recordset, by matching some strata criteria.

Usage

SampleTwins(x, stratanames = NULL, twins, method = c("srswor", "srswr", "poisson", "systematic"), pik, description = FALSE)

Arguments

x
the data to draw the sample from

stratanames
the stratanames to use

twins
the twin sample

method
method to select units; the following methods are implemented: simple random sampling without replacement (srswor), simple random sampling with replacement (srswr), Poisson sampling (poisson), systematic sampling (systematic); if "method" is missing, the default method is "srswor". See Strata.

pik
vector of inclusion probabilities or auxiliary information used to compute them; this argument is only used for unequal probability sampling (Poisson and systematic). If an auxiliary information is provided, the function uses the inclusion-probabilities function for computing these probabilities. If the method is "srswr" and the sample size is larger than the population size, this vector is normalized to one.

description
a message is printed if its value is TRUE; the message gives the number of selected units and the number of the units in the population. By default, the value is FALSE.
**Value**

The function produces an object, which contains the following information:

- **id**: the identifier of the selected units.
- **stratum**: the unit stratum.
- **prob**: the final unit inclusion probability.

Strata, sample

**Examples**

```r
m <- rbind(matrix(rep("nc",165), 165, 1, byrow=TRUE),
            matrix(rep("sc", 70), 70, 1, byrow=TRUE))
m <- cbind.data.frame(m, c(rep(1, 100), rep(2,50), rep(3,15),
                          rep(1,30), rep(2,40)), 1000*runif(235))
names(m) <- c("state","region","income")

# this would be our sample to be reproduced by a twin sample
d.smp <- m[sample(nrow(m), size=10, replace=TRUE),]

# draw the sample
s <- SampleTwins(x = m, stratanames=c("state","region"), twins = d.smp, method="srswor")
d.twin <- m[s$hid,]
d.twin
```

`SaveAs` saves an R object under a different name.

**Description**

An R object cannot be saved in binary mode under a different name using the default `save()` function. `SaveAs()` extends the save function for this option.

**Usage**

```r
SaveAs(x, objectname, file, ...)
```
ScheffeTest

Arguments

- `x` the object to save
- `objectname` the new name for the object.
- `file` a (writable binary-mode) connection or the name of the file where the data will be saved (when tilde expansion is done).
- `...` the dots are passed to the save function.

Author(s)

Andri Signorell <andri@signorell.net>

`save`

Examples

```r
x <- stats::runif(20)
SaveAs(x=x, objectname="NewX", file = "NewXFile.rda")
unlink("NewXFile.rda")
```

ScheffeTest

**Scheffe Test for Pairwise and Otherwise Comparisons**

Description

Scheffe’s method applies to the set of estimates of all possible contrasts among the factor level means, not just the pairwise differences considered by Tukey’s method.

Usage

```r
ScheffeTest(x, ...) 
```

```r
## S3 method for class 'aov'
ScheffeTest(x, which = NULL, contrasts = NULL, conf.level = 0.95, ...)
```

```r
## Default S3 method:
ScheffeTest(x, g = NULL, which = NULL, contrasts = NULL, conf.level = 0.95, ...)
```
Arguments

- **x**: either a fitted model object, usually an `aov` fit, when `g` is left to `NULL` or a response variable to be evaluated by `g` (which mustn’t be `NULL` then).
- **g**: the grouping variable.
- **which**: character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
- **contrasts**: a $r \times c$ matrix containing the contrasts to be computed, while $r$ is the number of factor levels and $c$ the number of contrasts. Each column must contain a full contrast (“sum”) adding up to 0. Note that the argument `which` must be defined, when non default contrasts are used. Default value of `contrasts` is `NULL`. In this case all pairwise contrasts will be reported.
- **conf.level**: numeric value between zero and one giving the confidence level to use. If this is set to `NA`, just a matrix with the p-values will be returned.
- **...**: further arguments, currently not used.

Value

A list of classes `c("PostHocTest")`, with one component for each term requested in `which`. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr.ci` giving the lower end point of the interval, `upr.ci` giving the upper end point and `pval` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "PostHocTest". The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

fm1 <- aov(breaks ~ wool + tension, data = warpbreaks)
ScheffeTest(x=fm1)
ScheffeTest(x=fm1, which="tension")
TukeyHSD(fm1)
```
# some special contrasts
y <- c(7, 33, 26, 27, 14, 19, 6, 11, 18, 14, 18, 19, 14, 9, 12, 6,
24, 7, 10, 1, 10, 42, 25, 8, 28, 30, 22, 17, 32, 28, 6, 1, 15, 9, 15,
2, 37, 13, 18, 23, 1, 3, 4, 6, 2)
group <- factor(c(1, 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2,
3, 3, 3, 4, 4, 4, 4, 4, 4, 4, 5, 5, 5, 5, 5, 5, 5, 6, 6, 6, 6, 6, 6, 6, 6, 6))

r.aov <- aov(y ~ group)
ScheffeTest(r.aov, contrasts=matrix( c(1,-0.5,-0.5,0,0,0,
                                  0,0,1,-0.5,-0.5), ncol=2) )

# just p-values:
ScheffeTest(r.aov, conf.level=NA)

---

**SD** *(Weighted) Standard Deviation*

**Description**
This function computes the standard deviation of the values in `x`. If `na.rm` is TRUE then missing values are removed before computation proceeds.

**Usage**

```r
SD(x, weights = NULL, na.rm = FALSE, ...)
```

**Arguments**

- `x` a numeric vector or an R object which is coercible to one by `as.double(x)`.
- `weights` a numerical vector of weights the same length as `x` giving the weights to use for elements of `x`.
- `na.rm` logical. Should missing values be removed?
- `...` further arguments passed to or from other methods.

**Details**
Like `var` this uses denominator $n - 1$.
The standard deviation of a zero-length vector (after removal of NAs if `na.rm = TRUE`) is not defined and gives an error. The standard deviation of a length-one vector is NA.

**See Also**

`var` for its square, and `mad`, the most robust alternative.

**Examples**

```r
SD(1:2)^2
```
Send a Mail Using Outlook as Mail Client

Description

Sending emails in R can be required in some reporting tasks. As we already have RDCOMClient available we wrap the send code in a function.

Usage

SendOutlookMail(to, cc = NULL, bcc = NULL, subject, body, attachment = NULL)

Arguments

to a vector of recipients
cc a vector of recipients receiving a carbon copy
bcc a vector of recipients receiving a blind carbon copy
subject the subject of the mail
body the body text of the mail
attachment a vector of paths to attachments

Value

Nothing is returned

Author(s)

Andri Signorell <andri@signorell.net> strongly based on code of Franziska Mueller

See Also

ToXL

Examples

## Not run:
SendOutlookMail(to=c("me@microsoft.com", "you@rstudio.com"), subject = "Some Info",
body = "Hi all\r Find the files attached\r Regards, Andri",
attachment = c("C:/temp/fileA.txt",
"C:/temp/fileB.txt"))

## End(Not run)
Add an Alpha Channel To a Color

Description

Add transparency to a color defined by its name or number. The function first converts the color to RGB and then appends the alpha channel.

Usage

SetAlpha(col, alpha = 0.5)

Arguments

col vector of two kind of R colors, i.e., either a color name (an element of colors()) or an integer i meaning palette()[i].
alpha the alpha value to be added. This can be any value from 0 (fully transparent) to 1 (opaque). NA is interpreted so as to delete a potential alpha channel. Default is 0.5.

Details

All arguments are recycled as necessary.

Value

Vector with the same length as col, giving the rgb-values extended by the alpha channel as hex-number (#rrggbbaa).

Author(s)

Andri Signorell <andri@signorell.net>

See Also

ColToHex, col2rgb

Examples

SetAlpha("yellow", 0.2)
SetAlpha(2, 0.5)  # red

Canvas(3)
DrawCircle(x=c(-1,0,1), y=c(1,-1,1), r.out=2, col=SetAlpha(2:4, 0.4))

x <- rnorm(15000)
par(mfrow=c(1,2))
plot(x, type="p", col="blue" )
plot(x, type="p", col=SetAlpha("blue", .2), main="Better insight with alpha channel" )
SetNames

Description

This is a convenience function that sets the names of an object and returns it including the new names. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just that the names can be assigned. In addition to the function setNames in base R the user can decide, whether rownames, colnames or simply the names are to be set. Names are recycled.

Usage

SetNames(x, ...)

Arguments

x an object for which a names attribute will be meaningful

... the names to be assigned to the object. This should be a character vector of names named rownames, colnames or names. Setting rownames=NULL would remove existing rownames. All kind of names can be changed at the same time. Default would be names. Abbreviations are supported.

Value

An object of the same sort as object with the new names assigned.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

setNames, Rename

Examples

SetNames(1:5, names=letters[1:5])

# the default, if no argument names are provided, is "names"
SetNames(1:5, letters[1:5])

tab <- table(d.pizza$driver, d.pizza$wine_delivered)
# rownames and columnnames can be set at the same time
SetNames(BinomCI(tab[,1], rowSums(tab)),
    rownames=rownames(tab), colnames=c("perc", "lci", "uci"))
# can also be used to set the names to an empty string
SetNames(diag(6), rownames="", colnames="")

### Shade

**Produce a Shaded Curve**

**Description**

Sometimes the area under a density curve has to be color shaded, for instance to illustrate a p-value or a specific region under the normal curve. This function draws a curve corresponding to a function over the interval \([\text{from}, \text{to}]\). It can plot also an expression in the variable \text{xname}, default \text{x}.

**Usage**

\[
\text{Shade}(\text{expr}, \text{col} = \text{par("fg")}, \text{breaks}, \text{density} = 10, \text{n} = 101, \text{xname} = "x", ...)\]

**Arguments**

- \text{expr}: the name of a function, or a \text{call} or an \text{expression} written as a function of \text{x} which will evaluate to an object of the same length as \text{x}.
- \text{col}: color to fill or shade the shape with. The default is taken from \text{par("fg")}.
- \text{breaks}: numeric, a vector giving the breakpoints between the distinct areas to be shaded differently. Should be finite as there are no plots with infinite limits.
- \text{density}: the density of the lines as needed in \text{polygon}.
- \text{n}: integer; the number of \text{x} values at which to evaluate. Default is 101.
- \text{xname}: character string giving the name to be used for the \text{x} axis.
- \ldots: the dots are passed on to \text{polygon}.

**Details**

Useful for shading the area under a curve as often needed for explaining significance tests.

**Value**

A list with components \text{x} and \text{y} of the points that were drawn is returned invisibly.

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

\text{polygon}, \text{curve}
Examples

```r
curve(dt(x, df=5), xlim=c(-6,6),
    main=paste("Student t-Distribution Probability Density Function, df = ", 5, ")", sep=""),
    type="n", las=1, ylab="probability", xlab="t"

Shade(dt(x, df=5), breaks=c(-6, qt(0.025, df=5), qt(0.975, df=5), 6),
    col=c(hred, hblue), density=c(20, 7))
```

---

**Shapiro-Francia Test for Normality**

**Description**

Performs the Shapiro-Francia test for the composite hypothesis of normality.

**Usage**

```r
ShapiroFranciaTest(x)
```

**Arguments**

- `x` a numeric vector of data values, the number of which must be between 5 and 5000. Missing values are allowed.

**Details**

The test statistic of the Shapiro-Francia test is simply the squared correlation between the ordered sample values and the (approximated) expected ordered quantiles from the standard normal distribution. The p-value is computed from the formula given by Royston (1993).

**Value**

A list of class `htest`, containing the following components:

- `statistic` the value of the Shapiro-Francia statistic.
- `p.value` the p-value for the test.
- `method` the character string “Shapiro-Francia normality test”.
- `data.name` a character string giving the name(s) of the data.

**Note**

The Shapiro-Francia test is known to perform well, see also the comments by Royston (1993). The expected ordered quantiles from the standard normal distribution are approximated by `qnorm(ppoints(x, a = 3/8))`, being slightly different from the approximation `qnorm(ppoints(x, a = 1/2))` used for the normal quantile-quantile plot by `qqnorm` for sample sizes greater than 10.
SiegelTukeyTest

Author(s)
Juergen Gross <gross@statistik.uni-dortmund.de>

ShapiroFranciaTest(runif(100, min = 2, max = 4))

---

SiegelTukeyTest  Siegel-Tukey Test For Equality In Variability

Description
Non-parametric Siegel-Tukey test for equality in variability. The null hypothesis is that the variability of x is equal between two groups. A rejection of the null hypothesis indicates that variability differs between the two groups. SiegelTukeyRank returns the ranks, calculated after Siegel Tukey logic.

Usage
SiegelTukeyTest(x, ...)

## Default S3 method:
SiegelTukeyTest(x, y, adjust.median = FALSE,
    alternative = c("two.sided", "less", "greater"),
    mu = 0, exact = NULL, correct = TRUE, conf.int = FALSE,
    conf.level = 0.95, ...)

## S3 method for class 'formula'
SiegelTukeyTest(formula, data, subset, na.action, ...)

SiegelTukeyRank(x, g, drop.median = TRUE)
Siegel-Tukey Test

Arguments

- **x, y**: numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
- **g**: a vector or factor object giving the group for the corresponding elements of x.
- **adjust.median**: Should between-group differences in medians be leveled before performing the test? In certain cases, the Siegel-Tukey test is susceptible to median differences and may indicate significant differences in variability that, in reality, stem from differences in medians. Default is FALSE.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **mu**: a number specifying an optional parameter used to form the null hypothesis. See Details.
- **exact**: a logical indicating whether an exact p-value should be computed. This is passed directly to wilcox.test.
- **correct**: a logical indicating whether to apply continuity correction in the normal approximation for the p-value.
- **conf.int**: a logical indicating whether a confidence interval should be computed.
- **conf.level**: confidence level of the interval.
- **formula**: a formula of the form `lhs ~ rhs` where `lhs` gives the data values and `rhs` the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
- **drop.median**: logical, defining whether the median of the combined samples should be left out, ensuring that there’s an even number of elements (which is a requirement of the Siegel-Tukey test). Defaults to TRUE.
- **...**: further arguments to be passed to or from methods.

Details

The Siegel-Tukey test has relatively low power and may, under certain conditions, indicate significance due to differences in medians rather than differences in variabilities (consider using the argument adjust.median). Consider also using mood.test or ansari.test.

Value

A list of class htest, containing the following components:

- **statistic**: Siegel-Tukey test (Wilcoxon test on tie-adjusted Siegel-Tukey ranks, after the median adjustment if specified).
- **p.value**: the p-value for the test
null.value is the value of the median specified by the null hypothesis. This equals the input argument mu.

alternative a character string describing the alternative hypothesis.

method the type of test applied

data.name a character string giving the names of the data.

---

**SignTest**

**Sign Test**

**Description**

Performs one- and two-sample sign tests on vectors of data.

**Usage**

SignTest(x, ...)

## Default S3 method:
SignTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
SignTest

mu = 0, conf.level = 0.95, ... )

## S3 method for class 'formula'
SignTest(formula, data, subset, na.action, ...)

Arguments

x numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
y an optional numeric vector of data values: as with x non-finite values will be omitted.
mu a number specifying an optional parameter used to form the null hypothesis. See Details.
alternative is a character string, one of "greater", "less", or "two.sided", or the initial letter of each, indicating the specification of the alternative hypothesis. For one-sample tests, alternative refers to the true median of the parent population in relation to the hypothesized value of the median.
conf.level confidence level for the returned confidence interval, restricted to lie between zero and one.
formula a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample test.

SignTest computes a “Dependent-samples Sign-Test” if both x and y are provided. If only x is provided, the “One-sample Sign-Test” will be computed.

For the one-sample sign-test, the null hypothesis is that the median of the population from which x is drawn is mu. For the two-sample dependent case, the null hypothesis is that the median for the differences of the populations from which x and y are drawn is mu. The alternative hypothesis indicates the direction of divergence of the population median for x from mu (i.e., "greater", "less", "two.sided").

The confidence levels are exact.
SignTest

Value

A list of class htest, containing the following components:

- **statistic**: the S-statistic (the number of positive differences between the data and the hypothesized median), with names attribute “S”.
- **parameter**: the total number of valid differences.
- **p.value**: the p-value for the test.
- **null.value**: is the value of the median specified by the null hypothesis. This equals the input argument mu.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: the type of test applied.
- **data.name**: a character string giving the names of the data.
- **conf.int**: a confidence interval for the median.
- **estimate**: the sample median.

**SmoothSpline**

*Formula Interface For smooth.spline*

**Description**

smooth.spline has no formula interface, which is sometimes inconvenient, if one simply wants to copy a formula of a linear model or a plot to spline.

**Usage**

SmoothSpline(x, ...)

## Default S3 method:
SmoothSpline(x, y = NULL, w = NULL, df, spar = NULL, cv = FALSE,
all.knots = FALSE, nknots = .nknots.smmspl, keep.data = TRUE,
df.offset = 0, penalty = 1, control.spar = list(),
tol = 0.000001 * IQR(x), ...)

## S3 method for class 'formula'
SmoothSpline(formula, data, subset, na.action, ...)
Arguments

- **x**: a vector giving the values of the predictor variable, or a list or a two-column matrix specifying x and y.
- **y**: responses. If y is missing or NULL, the responses are assumed to be specified by x, with x the index vector.
- **w**: optional vector of weights of the same length as x; defaults to all 1.
- **df**: the desired equivalent number of degrees of freedom (trace of the smoother matrix).
- **spar**: smoothing parameter, typically (but not necessarily) in (0, 1]. The coefficient λ of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of spar, see the details below.
- **cv**: ordinary (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; setting it to NA skips the evaluation of leverages and any score.
- **all.knots**: if TRUE, all distinct points in x are used as knots. If FALSE (default), a subset of x[] is used, specifically x[j] where the nknots indices are evenly spaced in 1:n, see also the next argument nknots.
- **nknots**: integer or function giving the number of knots to use when all.knots = FALSE. If a function (as by default), the number of knots is nknots(nx). By default for \(n_x > 49\) this is less than \(n_x\), the number of unique x values, see the Note.
- **keep.data**: logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.
- **df.offset**: allows the degrees of freedom to be increased by df.offset in the GCV criterion.
- **penalty**: the coefficient of the penalty for degrees of freedom in the GCV criterion.
- **control.spar**: optional list with named components controlling the root finding when the smoothing parameter spar is computed, i.e., missing or NULL, see below.

**Note** that this is partly experimental and may change with general spar computation improvements!

**low**: lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).
- **high**: upper bound for spar; defaults to +1.5.
- **tol**: the absolute precision (tolerance) used; defaults to 1e-4 (formerly 1e-3).
- **eps**: the relative precision used; defaults to 2e-8 (formerly 0.00244).
- **trace**: logical indicating if iterations should be traced.
- **maxit**: integer giving the maximal number of iterations; defaults to 500.

Note that spar is only searched for in the interval [low, high].

**tol** a tolerance for same-ness or uniqueness of the x values. The values are binned into bins of size tol and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).

**formula** a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

**data** The data frame from which the formula should be evaluated.
Some

subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... Other arguments to be passed to smooth.spline.

Author(s)
Andri Signorell <andri@signorell.net>

smooth.spline, lines.smooth.spline

Examples

plot(temperature ~ delivery_min, data=d.pizza)
lines(SmoothSpline(temperature ~ delivery_min, data=d.pizza))

Some(x, n = 6L, ...)  
## Default S3 method:
Some(x, n = 6L, ...)  
## S3 method for class 'data.frame'
Some(x, n = 6L, ...)  
## S3 method for class 'matrix'
Some(x, n = 6L, addrownums = TRUE, ...)

Arguments

x an object
n a single integer. If positive, size for the resulting object: number of elements for a vector (including lists), rows for a matrix or data frame or lines for a function. If negative, all but the n last/first number of elements of x.
addrownums if there are no row names, create them from the row numbers.
... arguments to be passed to or from other methods.

Description
For displaying the first and last elements of an object there are the functions head and tail. Sometimes one might want to see more randomly scattered elements. This function returns some random parts of a vector, matrix or a data frame. The order of the elements within the object will be preserved.
Some numeric checks

Details

For matrices, 2-dim tables and data frames, Some() returns some n rows when n > 0 or all but the some n rows when n < 0. Some.matrix() is not exported (unlike head.matrix).

If a matrix has no row names, then Some() will add row names of the form "[n,]" to the result, so that it looks similar to the last lines of x when printed. Setting addrownms = FALSE suppresses this behaviour.

I desisted from implementing interfaces for tables, ftables and functions, as this would not make much sense.

Value

An object (usually) like x but generally smaller.

Author(s)

Andri Signorell, basically copying and just slightly modifying Patrick Burns and R-Core code.

See Also

head

Examples

Some(letters)
Some(letters, n = -6L)

Some(freney.x, n = 10L)
Some(freney.y)

Description

Test if x contains only integer numbers, or if is numeric or if it is zero.

Usage

IsWhole(x, all = FALSE, tol = sqrt(.Machine$double.eps), na.rm = FALSE)
IsZero(x, tol = sqrt(.Machine$double.eps), na.rm = FALSE)
IsNumeric(x, length.arg = Inf, integer.valued = FALSE, positive = FALSE, na.rm = FALSE)
Some numeric checks

Arguments

- **x**: a (non-empty) numeric vector of data values.
- **all**: logical, specifying if the whole vector should be checked. If set to TRUE the function will return the result of all(IsWhole(x)).
- **tol**: tolerance to be used
- **length.arg**: integer, the length of the vector to be checked for.
- **integer.valued**: logical, should x be checked as integer?
- **positive**: logical, is x supposed to be positive?
- **na.rm**: logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.

Details

IsWhole is the suggested solution for checking for an integer value, as is.integer tests for class(x) == "integer" and does NOT test whether x (which might be of class "numeric") contains only integer numbers. (Why not simply implement it in base?)

IsZero tests float numeric values for being zero.

IsNumeric combines a test for numeric and integers.

Value

logical vector of the same dimension as x.

Author(s)

R-Core, Andri Signorell <andri@signorell.net>, Thomas W. Yee

Examples

```r
(x <- seq(1,5, by=0.5))
IsWhole(x) #--> TRUE FALSE TRUE ...

# ... These are people who live in ignorance of the Floating Point Gods.
# These pagans expect ... (Burns, 2011)” the following to be TRUE:
(.1 - .3 / 3) == 0

# they might be helped by
IsZero(.1 - .3 / 3)
```
Description

Calculate Somers’ Delta statistic, a measure of association for ordinal factors in a two-way table. The function has interfaces for a table (matrix) and for single vectors.

Usage

SomersDelta(x, y = NULL, direction = c("row", "column"), conf.level = NA, ...)

Arguments

x a numeric vector or a table. A matrix will be treated as table.

y NULL (default) or a vector with compatible dimensions to x. If y is provided, table(x,y,...) is calculated.

direction direction of the calculation. Can be "row" (default) or "column", where "row" calculates Somers’ D (R | C) ("column dependent").

conf.level confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.

... further arguments are passed to the function table, allowing i.e. to set useNA. This refers only to the vector interface.

Details

Somers’ D(C|R) and Somers’ D(R|C) are asymmetric modifications of \( \tau_b \) and Goodman-Kruskal’s Gamma. CIR indicates that the row variable x is regarded as the independent variable and the column variable y is regarded as dependent. Similarly, RIC indicates that the column variable y is regarded as the independent variable and the row variable x is regarded as dependent. It is logically very similar to Gamma, but differs in that it uses a correction only for pairs that are tied on the dependent variable. As Gamma and the Taus, D is appropriate only when both variables lie on an ordinal scale.

Somers’ D is computed as

\[
D(C|R) = \frac{P - Q}{n^2 - \sum(n_i^2)}
\]

where P equals twice the number of concordances and Q twice the number of discordances and \( n_i \) rowSums(tab). Its range lies [-1, 1]. The interpretation of \( d \) is analogous to Gamma.

Value

a single numeric value if no confidence intervals are requested
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval
Author(s)

Andri Signorell <andri@signorell.net>

References

See Also

There’s an implementation of Somers’s D in Frank Harrell’s *Hmisc* `somers2`, which is quite fast for large sample sizes. However it is restricted to computing Somers’ Dxy rank correlation between a variable x and a binary (0-1) variable y. *ConDisPairs* yields concordant and discordant pairs

Other association measures:

Examples

```r
# example in:
# pp. S. 1821

tab <- as.table(rbind(c(26,26,23,18,9),c(6,7,9,14,23)))

# Somers' D C|R
SomersDelta(tab, direction="column", conf.level=0.95)
# Somers' D R|C
SomersDelta(tab, direction="row", conf.level=0.95)
```

Sort

*Sort a Vector, a Matrix, a Table or a Data.frame*
Sort

Description

Sort a vector, a matrix, a table or a data.frame. The base sort function does not have an interface for classes other than vectors and coerces the whole world to a vector. This means you get a sorted vector as result while passing a matrix to sort.

Sort wraps the base sort function and adds an interface for sorting the rows of the named 2-dimensional data structures by the order of one or more of its columns.

Usage

Sort(x, ...)

## Default S3 method:
Sort(x, ...)
## S3 method for class 'matrix'
Sort(x, ord = NULL, decreasing = FALSE, na.last = TRUE, ...)
## S3 method for class 'table'
Sort(x, ord = NULL, decreasing = FALSE, na.last = TRUE, ...)
## S3 method for class 'data.frame'
Sort(x, ord = NULL, decreasing = FALSE, factorsAsCharacter = TRUE, na.last = TRUE, ...)

Arguments

x
a numeric, complex, character or logical vector, a factor, a table or a data.frame to be sorted.
decreasing
logical. Should the sort be increasing or decreasing?
factorsAsCharacter
logical. Should factors be sorted by the alphabetic order of their labels or by the order or their levels. Default is TRUE (by labels).
ord
vector of integers or column names. Defines the columns in a table, in a matrix or in a data.frame to be sorted for.
0 means row.names, 1:n the columns and n+1 the marginal sum. See examples.
na.last
for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed (see order.)
...
further arguments to be passed to or from methods.

Details

The sort order for factors is the order of their levels (which is particularly appropriate for ordered factors), and usually confusing for unordered factors, whose levels may be defined in the sequence in which they appear in the data (which normally is unordered).

Value

the sorted object.
SortMixed

Sort Strings with Embedded Numbers Based on Their Numeric Order

Description

These functions sort or order character strings containing embedded numbers so that the numbers are numerically sorted rather than sorted by character value. I.e. "Asprin 50mg" will come before "Asprin 100mg". In addition, case of character strings is ignored so that "a", will come before "B" and "C".

Usage

SortMixed(x, decreasing=FALSE, na.last=TRUE, blank.last=FALSE, numeric.type=c("decimal", "roman"), roman.case=c("upper","lower","both") )
OrderMixed(x, decreasing=FALSE, na.last=TRUE, blank.last=FALSE, numeric.type=c("decimal", "roman"), roman.case=c("upper","lower","both") )

Arguments

x vector to be sorted.
decreasing logical. Should the sort be increasing or decreasing? Note that decreasing=TRUE reverses the meanings of na.last and blanks.last.
na.last logical, controlling the treatment of NA values. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed.
blank.last logical, controlling the treatment of blank values. If TRUE, blank values in the data are put last; if FALSE, they are put first; if NA, they are removed.
numeric.type either "decimal" (default) or "roman". Are numeric values represented as decimal numbers (numeric.type="decimal") or as Roman numerals (numeric.type="roman")?
roman.case one of "upper", "lower", or "both". Are roman numerals represented using only capital letters ('IX') or lower-case letters ('ix') or both?

Details

I often have character vectors (e.g. factor labels), such as compound and dose, that contain both text and numeric data. This function is useful for sorting these character vectors into a logical order.

It does so by splitting each character vector into a sequence of character and numeric sections, and then sorting along these sections, with numbers being sorted by numeric value (e.g. "50" comes before "100"), followed by characters strings sorted by character value (e.g. "A" comes before "B") ignoring case (e.g. 'A' has the same sort order as 'a').

By default, sort order is ascending, empty strings are sorted to the front, and NA values to the end. Setting decreasing=TRUE changes the sort order to descending and reverses the meanings of na.last and blank.last.

Parsing looks for decimal numbers unless numeric.type="roman", in which parsing looks for roman numerals, with character case specified by roman.case.

Value

OrderMixed returns a vector giving the sort order of the input elements. SortMixed returns the sorted vector.

sort, order
Examples

## compound & dose labels
Treatment <- c("Control", "Asprin 10mg/day", "Asprin 50mg/day", "Asprin 100mg/day", "Acetomycin 100mg/day", "Acetomycin 1000mg/day")

## ordinary sort puts the dosages in the wrong order
sort(Treatment)

## but SortMixed does the 'right' thing
SortMixed(Treatment)

## Here is a more complex example
x <- rev(c("AA 0.50 ml", "AA 1.5 ml", "AA 500 ml", "AA 1500 ml", "EXP 1", "AA 1e3 ml", "A A A", "1 2 3 A", "NA", NA, "1e2", "", "=", "1A", "1 A", "100", "100A", "Inf")))

OrderMixed(x)

SortMixed(x) # Notice that plain numbers, including 'Inf' show up
# before strings, NAs at the end, and blanks at the
# beginning.

SortMixed(x, na.last=TRUE) # default
SortMixed(x, na.last=FALSE) # push NAs to the front

SortMixed(x, blank.last=FALSE) # default
SortMixed(x, blank.last=TRUE) # push blanks to the end

SortMixed(x, decreasing=FALSE) # default
SortMixed(x, decreasing=TRUE) # reverse sort order

## Roman numerals
chapters <- c("V. Non Sequiturs", "II. More Nonsense", "I. Nonsense", "IV. Nonesensical Citations", "III. Utter Nonsense")
SortMixed(chapters, numeric.type="roman")

## Lower-case Roman numerals
vals <- c("xix", "xii", "mcv", "iii", "iv", "dclxii", "cdxxi", "dcxcii", "cdxcvii", "dcmi", "cci")
(ordered <- SortMixed(vals, numeric.type="roman", roman.case="lower"))
RomanToInt(ordered)
Description
Calculate Spearman correlation coefficient and its confidence interval.

Usage
SpearmanRho(x, y = NULL, use = c("everything", "all.obs", "complete.obs",
"na.or.complete","pairwise.complete.obs"),
conf.level = NA)

Arguments
x a numeric vector, an ordered factor, matrix or data frame. An ordered factor will be coerced to numeric.
y NULL (default) or a vector, an ordered factor, matrix or data frame with compatible dimensions to x. An ordered factor will be coerced to numeric.
use an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
conf.level confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.

Details
The function calculates Spearman’s rho statistic by means of cor(...,method="spearman"). The confidence intervals are calculated via z-Transformation.

Value
Either a single numeric value, if no confidence interval is required,
or a vector with 3 elements for estimate, lower and upper confidence interval.

**Formula Interface for Split**

**Description**

Implementation of a simple formula interface for the `split` function.

**Usage**

```r
## S3 method for class 'formula'
split(x, f, drop = FALSE, data = NULL, ...)
```

**Arguments**

- `x` a formula of the form `y ~ x`.
- `f` a 'factor' in the sense that `as.factor(f)` defines the grouping, or a list of such factors in which case their interaction is used for the grouping.
- `drop` logical indicating if levels that do not occur should be dropped (if `f` is a factor or a list). Defaults to FALSE.
- `data` the data frame from which the formula should be evaluated.
- `...` other arguments to be passed to `split`.

**Author(s)**

Andri Signorell <andri@signorell.net>

x <- 1:10
SplitAt(x, pos=c(3, 8))
```
SplitPath

Split Path In Drive, Path, Filename

Description
Split a full path in its components. This is specifically an issue in Windows and not really interesting for other OSs.

Usage
SplitPath(path, last.is.file = NULL)

Arguments
path a path
last.is.file logical, determining if the basename should be interpreted as filename or as last directory. If set to NULL (default), the last entry will be interpreted if the last character is either \ or / and as filename else.

Value
A list, containing the following components:

normpath the normalized path as returned by normalizePath
drive the drive if the OS is Windows, NA else
dirname the path without directory and without filename
fullfilename the filename including extension
filename the filename without extension
extension the file extension

SplitPath(path)

path &lt; "C:/Documents/Projects/Import/"
SplitPath(path)
SpreadOut

Spread Out a Vector of Numbers To a Minimum Interval

Description

Spread the numbers of a vector so that there is a minimum interval between any two numbers (in ascending or descending order). This is helpful when we want to place textboxes on a plot and ensure, that they do not mutually overlap.

Usage

SpreadOut(x, mindist = NULL, cex = 1.0)

Arguments

x a numeric vector which may contain NAs.
mindist the minimum interval between any two values. If this is left to NULL (default) the function will check if a plot is open and then use 90% of \texttt{strheight()}. cex numeric character expansion factor; multiplied by \texttt{par("cex")} yields the final character size; the default NULL is equivalent to 1.

Details

SpreadOut() starts at or near the middle of the vector and increases the intervals between the ordered values. NAs are preserved. SpreadOut() first tries to spread groups of values with intervals less than mindist out neatly away from the mean of the group. If this doesn’t entirely succeed, a second pass that forces values away from the middle is performed.

SpreadOut() can also be used to avoid overplotting of axis tick labels where they may be close together.

Value

On success, the spread out values. If there are less than two valid values, the original vector is returned.

Note

This function is based on \texttt{plotrix::spreadout()} and has been integrated here with some minor changes.
Stamp

Jim Lemon <jim@bitwrit.com.au>
some extensions Andri Signorell <andri@signorell.net>

See Also

strheight()

Examples

SpreadOut(c(1, 3, 3, 3, 3, 5), 0.2)
SpreadOut(c(1, 2.5, 2.5, 3.5, 3.5, 5), 0.2)
SpreadOut(c(5, 2.5, 2.5, NA, 3.5, 1, 3.5, NA), 0.2)

# this will almost always invoke the brute force second pass
SpreadOut(rnorm(10), 0.5)

Date/Time/Directory Stamp the Current Plot

Description

Stamp the current plot in the extreme lower right corner. A free text or expression can be defined as text to the stamp.

Usage

Stamp(txt = NULL, las = par("las"), cex = 0.6)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>txt</td>
<td>an optional single text string. If it is not given, the function will look for a defined option named stamp. If not found the current date will be taken as text. If the stamp option is defined as expression the function will evaluate it. This can be used to define dynamic texts.</td>
</tr>
<tr>
<td>las</td>
<td>numeric in 1,3, defining direction of the text. 1 means horizontal, 3 vertical. Default is taken from par(&quot;las&quot;).</td>
</tr>
<tr>
<td>cex</td>
<td>numeric character expansion factor; multiplied by par(&quot;cex&quot;) yields the final character size. Defaults to 0.6.</td>
</tr>
</tbody>
</table>

Details

The text can be freely defined as option. If user and date should be included by default, the following option using an expression will help:

DescToolsOptions(stamp=expression(gettextf('"%s/%s",
   Sys.getenv('USERNAME'), Format(Today(), fmt='yyy-mm-dd') )))

For R results may not be satisfactory if `par(mfrow=)` is in effect.

plot(1:20)
Stamp()

StdCoef | Standardized Model Coefficients
--------|---------------------------------

Description
Standardize model coefficients by Standard Deviation or Partial Standard Deviation.

Usage
StdCoef(x, partial.sd = FALSE, ...)
PartialSD(x)

Arguments
x | a fitted model object.
partial.sd | logical, if set to TRUE, model coefficients are multiplied by partial SD, otherwise they are multiplied by the ratio of the standard deviations of the independent variable and dependent variable.
... | additional arguments passed to coefTable, e.g. dispersion.

Details
The standardized coefficients are meant to allow for a comparison of the importance of explanatory variables that have different variances. Each of them shows the effect on the response of increasing its predictor X(j) by one standard deviation, as a multiple of the response’s standard deviation. This is often a more meaningful comparison of the relevance of the input variables.

Note, however, that increasing one X(j) without also changing others may not be possible in a given application, and therefore, interpretation of coefficients can always be tricky. Furthermore, for binary input variables, increasing the variable by one standard deviation is impossible, since an increase can only occur from 0 to 1, and therefore, the standardized coefficient is somewhat counter-intuitive in this case.
Standardizing model coefficients has the same effect as centring and scaling the input variables. “Classical” standardized coefficients are calculated as $\beta_i^* = \beta_i \frac{s_{X_i}}{s_y}$, where $\beta$ is the unstandardized coefficient, $s_{X_i}$ is the standard deviation of associated dependent variable $X_i$ and $s_y$ is SD of the response variable.

If the variables are intercorrelated, the standard deviation of $X_i$ used in computing the standardized coefficients $\beta_i^*$ should be replaced by a partial standard deviation of $X_i$ which is adjusted for the multiple correlation of $X_i$ with the other $X$ variables included in the regression equation. The partial standard deviation is calculated as $s^*_{X_i} = s_{X_i} \sqrt{VIF(X_i)}^{-0.5} \left(\frac{n-1}{n-p}\right)^{0.5}$, where $VIF$ is the variance inflation factor, $n$ is the number of observations and $p$ number of predictors in the model. Coefficient is then transformed as $\beta_i^* = \beta_i s^*_{X_i}$.

Value

A matrix with at least two columns for standardized coefficient estimate and its standard error. Optionally, third column holds degrees of freedom associated with the coefficients.

### Str

**Compactly Display the Structure of any R Object**

**Description**

Basically a wrapper for `str()`, extended with an enumeration for the variables of a data.frame.

**Usage**

```r
Str(x, ...)
```

**Arguments**

- `x` any R object about which you want to have some information.
- `...` dots are passed to `str`.

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

`str`

**Examples**

```r
Str(d.pizza)
```
StrAbbr

String Abbreviation

Description
Abbreviate a character vector. The function includes starting from the first character as many characters as there are needed to result in a vector of unique values.

Usage
`StrAbbr(x, minchar = 1, method = c("left", "fix"))`

Arguments
- `x` character vector to be abbreviated
- `minchar` integer, minimal number of characters for the abbreviations.
- `method` one out of `left` or `fix`. While `left` restricts the result to as many characters are needed to ensure uniqueness, does `fix` yield a vector with all the elements being as long, as the the longest needed substring for differentiating the terms.

Value
The abbreviated strings.

Author(s)
Andri Signorell <andri@signorell.net>

See Also
`abbreviate`, `StrTrunc`, `StrTrim`

Examples
```r
x <- c("Aaron", "Aaramis", "Berta", "Bello", "Claudia", "Cardinale", "Doretta", "Emilia")
StrAbbr(x, minchar=2, method="left")
StrAbbr(x, minchar=2, method="fix")
```
Description

Align a vector of strings to the left, to the right, to the center or to the first occurrence of a specified character, e.g., to the decimal separator. Alignment is achieved by padding the strings with empty spaces (which evidently only will have an alignment effect if the text is displayed with a monospaced font).

Usage

\texttt{StrAlign(x, sep = "\r")}

Arguments

- \texttt{x}: a character vector to be aligned.
- \texttt{sep}: the character on whose position the strings will be aligned. Left alignment can be requested by setting \texttt{sep = "\l"}, right alignment by \texttt{"\r"} and center alignment by \texttt{"\c"}. Mind the backslashes, as if they are omitted, strings would be aligned to the character \texttt{l}, \texttt{r} or \texttt{c} respectively. Default value is \texttt{"\r"}, thus right alignment.

Details

Alignment to the left, right or center leave no room for misinterpretation. The function will determine the maximum string size in the vector, resize all the strings to this size by padding empty spaces either at the beginning or at the end of the strings. When it comes to center strings, it’s not clear where to place strings with an even length in case the maximum length is odd (or vice versa). We will put the shorter distance of an uneven string at the left. Any specific length of the strings can be created by \texttt{StrPad} if required.

In case of a given separator the strings will be aligned towards this separator. If a string does not contain the separator, the affected string will be aligned as if it had a separator as last character. This seems to be a good default, when integer numbers are to be aligned with numerical values. Note that the character length of the resulting strings can exceed the maximum length of the supplied strings.

The character strings will not be pruned of whitespaces, if the requested alignment does not explicitly require it. \texttt{StrTrim} can be used for that.

Value

- a character vector containing the aligned strings

Stratified Sampling

Description

Stratified sampling with equal/unequal probabilities.

Usage

Strata(x, stratanames = NULL, size, method = c("srswor", "srswr", "poisson", "systematic"), pik, description = FALSE)

Arguments

x a data frame or a matrix; its number of rows is n, the population size.
stratanames vector of stratification variables.
size vector of stratum sample sizes (in the order in which the strata are given in the input data set).
method method to select units; implemented are: a) simple random sampling without replacement ("srswor"), b) simple random sampling with replacement ("srswr"), c) Poisson sampling ("poisson"), d) systematic sampling ("systematic") (default is "srswor").
pik vector of inclusion probabilities or auxiliary information used to compute them; this argument is only used for unequal probability sampling (Poisson and systematic). If an auxiliary information is provided, the function uses the inclusion-probabilities function for computing these probabilities. If the method is "srswr"
and the sample size is larger than the population size, this vector is normalized to one.

**description** a message is printed if its value is TRUE; the message gives the number of selected units and the number of the units in the population. By default, the value is FALSE.

**Value**

The function produces an object, which contains the following information:

- `id` the identifier of the selected units.
- `stratum` the unit stratum.
- `prob` the final unit inclusion probability.

**Examples**

```r
# Example from An and Watts (New SAS procedures for Analysis of Sample Survey Data)
# generates artificial data (a 235X3 matrix with 3 columns: state, region, income).
# the variable "state" has 2 categories ('nc' and 'sc').
# the variable "region" has 3 categories (1, 2 and 3).
# the sampling frame is stratified by region within state.
# the income variable is randomly generated
m <- rbind(matrix(rep("nc",165), 165, 1, byrow=TRUE),
           matrix(rep("sc", 70), 70, 1, byrow=TRUE))
m <- cbind.data.frame(m, c(rep(1, 100), rep(2,50), rep(3,15),
                          rep(1, 30), rep(2, 40)), 1000 * runif(235))
names(m) <- c("state", "region", "income")

# computes the population stratum sizes
table(m$region, m$state)

# not run
# nc  sc
# 1 100 30
# 2 50 40
# 3 15 0
# there are 5 cells with non-zero values
# one draws 5 samples (1 sample in each stratum)
# the sample stratum sizes are 10,5,10,4,6, respectively
# the method is 'srswor' (equal probability, without replacement)
```
s <- Strata(m, c("region", "state"), size=c(10, 5, 10, 4, 6), method="srswor")

# extracts the observed data
data.frame(income=m[s$id, "income"], s)

# see the result using a contingency table
table(s$region, s$state)

# The same data as in Example 1
# the method is 'systematic' (unequal probability, without replacement)
# the selection probabilities are computed using the variable 'income'
s <- Strata(m,c("region", "state"), size=c(10, 5, 10, 4, 6),
method="systematic", pik=m$income)

# extracts the observed data
data.frame(income=m[s$id, "income"], s)

# see the result using a contingency table
table(s$region, s$state)

---

**StrCap**

*Capitalize the First Letter of a String*

**Description**

Capitalize the first letter of each element of the string vector.

**Usage**

```r
StrCap(x, method=c("first", "word", "title"))
```

**Arguments**

- `x`: string to be capitalized.
- `method`: one out of "first" (default), "word", "title". "first" will only capitalize the first character of a string. "word" will capitalize all found words and "title" will also capitalize wordwise, but leave out: a, an, the, at, by, for, in, of, on, to, up, and, as, but, s, or and nor.

**Value**

Returns a vector of characters with the first letter capitalized

**Author(s)**

Charles Dupont <charles.dupont@vanderbilt.edu>, Andri Signorell <andri@signorell.net> (methods word and title)
Examples

# capitalize first character
StrCap(c("Hello", "bob", "daN"))
# but not all...
StrCap(c("Hello bob, how are you?", "And you, DANIEL?"))

# wordwise
StrCap(c("Capitalize all words in titles of publications and documents",
        "but Up and UP, not all and all", NA), method="word")

# wordwise omitting the ones listed above
StrCap(c("Capitalize all words in titles of publications and documents",
        "but Up and UP, not all and all", NA), method="title")

# do not touch non alphabetic characters
z <- c("Lorem ipsum dolor", "-- sit amet", "consectetur --", " adipiscing elit ",
        "sed, --(do) / ++$eiusmod")
StrCap(z, method="title")

---

**StrChop**  
*Split a String into a Number of Sections of Defined Length*

Description

Splitting a string into a number of sections of defined length is needed, when we want to split a table given as a number of lines without separator into columns. The cutting points can either be defined by the lengths of the sections or directly by position.

Usage

StrChop(x, len, pos)

Arguments

- **x**  
The string to be cut in pieces.

- **len**  
a vector with the lengths of the pieces.

- **pos**  
a vector of cutting positions. Will be ignored when len has been defined.

Details

If length is going over the end of the string the last part will be returned, so if the rest of the string is needed, it’s possible to simply enter a big number as last part length.

len and pos can’t be defined simultaneously, only alternatively.

Typical usages are

StrChop(x, len)
StrChop(x, pos)
**StrCountW**

Count Words in a String

**Description**

Count the number of words that appear within a character string.

**Usage**

`StrCountW(x)`

**Arguments**

- `x` : a vector of strings to be parsed.

**Details**

This is just a wrapper for a fine regexp. It uses the expression `\b\W+\b` to separate the words. The code `\W` is equivalent to `^[[:alnum:]_]` whereas `[:alnum:]` contains `[:alpha:]` and `[:digit:]`. So everything that is not an alphanumeric character, a digit or a _ (underscore) is used as separator for the words to be counted.

**Value**

an integer defining the number of word in the string

**Examples**

```r
x <- paste(letters, collapse="")
StrChop(x=x, len = c(3,5,2))

# and with the rest integrated
StrChop(x=x, len = c(3, 5, 2, nchar(x)))

# cutpoints at 5th and 10th position
StrChop(x=x, pos=c(5, 10))
```

StrCountW(c("This is a", "text in more", "than one line."))

StrDist
Compute Distances Between Strings

Description
StrDist computes distances between strings following to Levenshtein or Hamming method.

Usage
StrDist(x, y, method = "levenshtein", mismatch = 1, gap = 1, ignore.case = FALSE)

Arguments
x character vector, first string.
y character vector, second string.
method character, name of the distance method. This must be "levenshtein", "normlevenshtein" or "hamming". Default is "levenshtein", the classical Levenshtein distance.
mismatch numeric, distance value for a mismatch between symbols.
gap numeric, distance value for inserting a gap.
ignore.case if FALSE (default), the distance measure will be case sensitive and if TRUE, case is ignored.
Details

The function computes the Hamming and the Levenshtein (edit) distance of two given strings (sequences). The Hamming distance between two vectors is the number mismatches between corresponding entries.

In case of the Hamming distance the two strings must have the same length.

In case of the Levenshtein (edit) distance a scoring and a trace-back matrix are computed and are saved as attributes "ScoringMatrix" and "TraceBackMatrix". The numbers in the trace-back matrix reflect insertion of a gap in string \( y \) (1), match/mismatch (2), and insertion of a gap in string \( x \) (3).

The edit distance is useful, but normalizing the distance to fall within the interval \([0,1]\) is preferred because it is somewhat difficult to judge whether an LD of for example 4 suggests a high or low degree of similarity. The method "normlevenshtein" for normalizing the LD is sensitive to this scenario. In this implementation, the Levenshtein distance is transformed to fall in this interval as follows:

\[
\text{ind} = 1 - \frac{\text{ld}}{\max(\text{length}(x), \text{length}(y))}
\]

where \( \text{ld} \) is the edit distance and \( \max(\text{length}(x), \text{length}(y)) \) denotes that we divide by the length of the larger of the two character strings. This normalization, referred to as the Levenshtein normalized distance (Ind), yields a statistic where 1 indicates perfect agreement between the two strings, and a 0 denotes imperfect agreement. The closer a value is to 1, the more certain we can be that the character strings are the same; the closer to 0, the less certain.

Value

\text{StrDist} returns an object of class "dist"; cf. dist.

Note

For distances between strings and for string alignments see also Bioconductor package Biostrings

## Hamming distance
StrDist(x, y, method="hamming")
```

---

**StrExtract**  
*Extract Part of a String*

---

**Description**

Extract a part of a string, defined as regular expression.

**Usage**

```r
StrExtract(x, pattern, ...)
```

**Arguments**

- `x`: a character vector where matches are sought, or an object which can be coerced by `as.character` to a character vector.
- `pattern`: character string containing a regular expression (or character string for `fixed = TRUE`) to be matched in the given character vector. Coerced by `as.character` to a character string if possible. If a character vector of length 2 or more is supplied, the first element is used with a warning. Missing values are not allowed.
- `...`: the dots are passed to the the internally used function `regexpr()`, which allows to use e.g. Perl-like regular expressions.

**Details**

The function wraps `regexpr` and `regmatches`.

**Value**

A character vector.

**Author(s)**

Andri Signorell <andri@signorell.net>
StrIsNumeric  Does a String Contain Only Numeric Data

Description

Check whether a string does only contain numeric data.

Usage

StrIsNumeric(x)

Arguments

x  a character vector

Value

a logical vector with the same dimension as x

Author(s)

Andri Signorell <andri@signorell.net>

See Also

Other string functions, e.g. StrTrunc

Examples

x <- c("123", "-3.141", "foobar123")
StrIsNumeric(x)
StrLeft, StrRight

Returns the Left Or the Right Part Of a String

Description

Returns the left part or the right part of a string. The number of characters are defined by the argument n. If n is negative, this number of characters will be cut off from the other side.

Usage

\[
\begin{align*}
\text{StrLeft}(x, n) \\
\text{StrRight}(x, n)
\end{align*}
\]

Arguments

- **x**: a vector of strings.
- **n**: a positive or a negative integer, the number of characters to cut. If n is negative, this number of characters will be cut off from the right with StrLeft and from the right with StrRight.
  
  n will be recycled.

Details

The functions StrLeft and StrRight are simple wrappers to \texttt{substr}.

Value

the left (right) n characters of x

Author(s)

Andri Signorell <andri@signorell.net>

See Also

\texttt{substr}, \texttt{StrTrim}

Examples

\[
\begin{align*}
\text{StrLeft}("Hello world!", n=5) \\
\text{StrLeft}("Hello world!", n=-5) \\
\text{StrRight}("Hello world!", n=6) \\
\text{StrRight}("Hello world!", n=-6) \\
\text{StrLeft}(c("Lorem", "ipsum", "dolor","sit","amet"), n=2) \\
\text{StrRight}(c("Lorem", "ipsum", "dolor","sit","amet"), n=c(2,3))
\end{align*}
\]
**StrPad**

*Pad a String With Justification*

**Description**

StrPad will fill a string `x` with defined characters to fit a given length.

**Usage**

`StrPad(x, width = NULL, pad = " ", adj = "left")`

**Arguments**

- `x`: a vector of strings to be padded.
- `width`: resulting width of padded string. If `x` is a vector and `width` is left to `NULL`, it will be set to the length of the largest string in `x`.
- `pad`: string to pad with. Will be repeated as often as necessary. Default is " ".
- `adj`: adjustment of the old string, one of "left", "right", "center". If set to "left" the old string will be adjusted on the left and the new characters will be filled in on the right side.

**Details**

If a string `x` has more characters than `width`, it will be chopped on the length of `width`.

**Value**

the string

**Author(s)**

Christian W. Hoffmann <c-w.hoffmann@sunrise.ch>

some extensions Andri Signorell <andri@signorell.net>

**Examples**

```r
StrPad("My string", 25, "XoX", "center")
# [1] "XoXoXoXMy stringXoXoXoXX"
```
StrPos

Find Position of First Occurrence Of a String

Description

Returns the numeric position of the first occurrence of a substring within a string. If the search string is not found, the result will be NA.

Usage

StrPos(x, pattern, pos = 1, ...)

Arguments

x a character vector in which to search for the pattern, or an object which can be coerced by as.character to a character vector.

pattern character string (search string) containing the pattern to be matched in the given character vector. This can be a character string or a regular expression.

pos integer, defining the start position for the search within x. The result will then be relative to the begin of the truncated string. Will be recycled.

... the dots are passed to the function regexpr.

Details

This is just a wrapper for the function regexpr.

Value

a vector of the first position of pattern in x

Author(s)

Andri Signorell <andri@signorell.net>

See Also

StrChop, regexpr

Examples

StrPos(x = levels(d.pizza$driver), pattern = "t")
StrRev

Reverse a String

Description
Returns a string in reverse order.

Usage
StrRev(x)

Arguments
x a string to be processed.

Value
string

Author(s)
Andri Signorell <andri@signorell.net> solely copying R core code from strsplit example

String functions: nchar, match, grep, regexpr, substr, sub, gsub, StrTrunc, StrDist

Examples
StrRev("home")
StrRev("Anna")

StrSpell

Spell a String Using the NATO Phonetic or the Morse Alphabet

Description
The function splits a string into single characters and returns their representation in either the NATO
phonetic alphabet or the Morse alphabet. The 26 code words in the NATO phonetic alphabet are
assigned to the 26 letters of the English alphabet in alphabetical order as follows: Alfa, Bravo,
Charlie, Delta, Echo, Foxtrot, Golf, Hotel, India, Juliett, Kilo, Lima, Mike, November, Oscar, Papa,
Quebec, Romeo, Sierra, Tango, Uniform, Victor, Whiskey, X-ray, Yankee, Zulu. Digits 0-9 are also
supported.

Usage
StrSpell(x, upr = "CAP", type = c("NATO", "Morse"))
Arguments

- `x` character, the string to be encoded.
- `upr` character, a shortcut to be used to characterise capital letters. Ignored if `type` is set to "Morse". No distinction is made between upper and lower case if `upr` is set to NA or to an empty string "".
- `type` the type of phonetic alphabet, either "NATO" or "Morse".

Value

a character vector containing the code words

Author(s)

Andri Signorell <andri@signorell.net>

References

https://en.wikipedia.org/wiki/NATO_phonetic_alphabet

See Also

strsplit

Examples

# ... ever had to communicate a password by phone? ;-)  
StrSpell("Yailov9teb6i")

paste(StrSpell("Andri", type="Morse"), collapse="|

StrTrim

Remove Leading/Trailing Whitespace From A String

Description

The function removes all spaces, tabs and newlines from the beginning and end of the supplied string. If these whitespace characters occur in the middle of the string, they are preserved. Trimming with method "left" deletes only leading whitespaces, "right" only trailing. Designed for users who were socialized by SQL.

Usage

StrTrim(x, pattern = "\t\n", method = "both")
Arguments

x         the string to be trimmed.
pattern   the pattern of the whitespaces to be deleted, defaults to space, tab and newline: " \t\n".
method    one out of "both" (default), "left", "right". Determines on which side the string should be trimmed.

Details

The functions are defined depending on method as
both: gsub( pattern=gettextf("^[%s]+|[%s]+$", pattern, pattern), replacement="", x=x)
left: gsub( pattern=gettextf("^[%s]+",pattern), replacement="", x=x)
right: gsub( pattern=gettextf("[%s]+$",pattern), replacement="", x=x)

Value

the string x without whitespaces

Author(s)

Andri Signorell <andri@signorell.net>

See Also

String functions: trimws, nchar, match, grep, regexpr, substr, sub, gsub, StrTrunc, StrDist

Examples

StrTrim(" Hello world! ")

StrTrim(" Hello world! ", method="left")
StrTrim(" Hello world! ", method="right")

# user defined pattern
StrTrim(" ..Hello ... world! ", pattern=" / /."")

StrTrunc

Truncate Strings and Add Ellipses If a String is Truncated.

Description

Truncates one or more strings to a specified length, adding an ellipsis (...) to those strings that have been truncated. Use formatC to justify the strings if needed.

Usage

StrTrunc(x, maxlen = 20)
**Description**

Extract all numeric values from a string using a regular expression and return a list of all found values. If there are several, the values can be either pasted and/or casted from characters to numeric values.

**Usage**

```r
StrVal(x, paste = FALSE, as.numeric = FALSE, dec = getOption("OutDec"))
```

---

**Arguments**

- **x**: a vector of strings.
- **maxlen**: the maximum length of the returned strings.

**Value**

The string(s) passed as ‘x’ now with a maximum length of ‘maxlen’ + 3 (for the ellipsis).

**Author(s)**

Andri Signorell,
following an idea of Jim Lemon in `truncString()`

**See Also**

String functions: `nchar`, `match`, `grep`, `regexpr`, `substr`, `sub`, `gsub`, `StrTrim`, `StrDist`
Arguments

- **x**: a character vector
- **paste**: should separately extracted numbers be pasted together? This can be useful to reverse a prior format action. Default is `FALSE`.
- **as.numeric**: logical value, determining if the extracted values should be converted to a number or be returned as characters. Default is `FALSE`.
- **dec**: character string containing a single character. The preferred character to be used as the decimal point. Defaults `getOption("OutDec")`.

Details

If there are multiple numbers in the same string to paste and cast to numeric, pasting will be done first and after pasting the conversion will be performed. So if for example the numbers in `x = "34 way 066"` should be extracted `StrVal(x,paste = TRUE,as.numeric = TRUE)` will lead to `34066`. This is a useful choice for converting formatted numbers having some kind of `bigmark`.

Value

depending on the results the function will return either a character vector, in the case every element of `x` contained only one number, or a list of character vectors containing the found numbers.

Author(s)

Andri Signorell <andri@signorell.net>, Markus Naepflin <markus@naepfl.in> provided an optimized regex

Examples

```r
# a simple vector with only one number per element
StrVal(x=c("week 1", "week 3", "week 4", "week 5"))

# several numbers per element, extract each part, do not paste and return characters
StrVal(x=c("This is 1. place: 45.2", "none", "12.1 but -2.7 follow, 10.2e23 "),
  paste = FALSE, as.numeric = FALSE)

# critical are numbers combined with signs, where we sequentially extract valid numbers
StrVal(x=c("78-23-99", "1e-15-34*789+9", "- 34values"),
  paste = FALSE, as.numeric = FALSE)

# a typical use case for this function is to reverse a previously applied number format
#
x <- c(100000, 4564654632, -456463)
xf <- Format(x, big.mark=""')
StrVal(xf, paste = TRUE, as.numeric = TRUE)
```
StuartMaxwellTest

StrVal(xf, paste = TRUE, as.numeric = FALSE)
StrVal(xf, paste = FALSE, as.numeric = TRUE)
StrVal(xf, paste = FALSE, as.numeric = FALSE)

# use an alternative decimal point
StrVal("8 452,12", dec="",)

StuartMaxwellTest Stuart-Maxwell Marginal Homogeneity Test

Description

This function computes the marginal homogeneity test for a $k \times k$ matrix of assignments of objects
to $k$ categories or an $n \times 2 \times k$ matrix of category scores for $n$ data objects by two raters. The
statistic is distributed as chi-square with $k-1$ degrees of freedom.
It can be viewed as an extention of McNemar test to $k \times k$ table.

Usage

StuartMaxwellTest(x, y = NULL)

Arguments

x either a 2-way contingency table in matrix form, or a factor object.
y a factor object; ignored if x is a matrix.

Details

The null is that the probabilities of being classified into cells [i,j] and [j,i] are the same.
If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be
nonnegative integers. Otherwise, both x and y must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed
from these.

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.
parameter the degrees of freedom.
p.value the p-value of the test.
method a character string indicating what type of test was performed.
data.name a character string giving the name of the data.

Author(s)

Andri Signorell <andri@signorell.net>, based on Code from Jim Lemon
StuartTauC

<table>
<thead>
<tr>
<th>StuartTauC</th>
<th>Stuart τ_c</th>
</tr>
</thead>
</table>

Description

Calculate Stuart’s τ_c statistic, a measure of association for ordinal factors in a two-way table. The function has interfaces for a table (matrix) and for single vectors.

Usage

StuartTauC(x, y = NULL, conf.level = NA, ...)

Arguments

x          a numeric vector or a table. A matrix will be treated as table.
y          NULL (default) or a vector with compatible dimensions to x. If y is provided, table(x,y,...) is calculated.
conf.level confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
...         further arguments are passed to the function table, allowing i.e. to set useNA. This refers only to the vector interface.
Details

Stuart’s \( \tau_c \) makes an adjustment for table size in addition to a correction for ties. \( \tau_c \) is appropriate only when both variables lie on an ordinal scale.

It is estimated by

\[
\tau_c = \frac{m \cdot (P - Q)}{n^2 \cdot (m - 1)}
\]

where \( P \) equals twice the number of concordances and \( Q \) twice the number of discordances, \( n \) is the total amount of observations and \( m = \min(R, C) \). The range of \( \tau_c \) is \([-1, 1]\).

Value

a single numeric value if no confidence intervals are requested,
and otherwise a numeric vector with 3 elements for the estimate, the lower and the upper confidence interval

Author(s)

Andri Signorell <andri@signorell.net>

**SysInfo**  

**System Information**

**Description**

SysInfo is a convenience function to compile some information about the computing system and environment used.

**Usage**

```r
SysInfo()
FindRProfile()
```

**Details**

The function `SysInfo` is mainly used to save the system environment information in ncdf files containing the results of some calculations.

`FindRProfile` returns path candidates where the profile could be found.

**Value**

character string with all version and system information of the current R system

**Author(s)**

Jannis v. Buttler <jbuttlar@bgc-jena.mpg.de>, Andri Signorell <andri@signorell.net>

---

**TextContrastColor**  

**Choose Textcolor Depending on Background Color**

**Description**

Text of a certain color when viewed against certain backgrounds can be hard to see. `TextContrastColor` returns either black or white depending on which has the better contrast.

**Usage**

```r
TextContrastColor(col, white = "white", black = "black", method = c("glynn", "sonego"))
```
Arguments

| col         | vector of any of the three kind of R colors, i.e., either a color name (an element of `colors()`), a hexadecimal string of the form "#rrggbbaa" or "#rrggbbaa" (see `rgb`), or an integer i meaning `palette()[i]`. Non-string values are coerced to integer. |
| white      | the color for the dark backgrounds, default is "white". |
| black      | the color for the bright backgrounds, default is "black" |
| method     | defines the algorithm to be used. Can be one out of "glynn" or "sonego". See details. |

Details

A simple heuristic in defining a text color for a given background color, is to pick the one that is "farthest" away from "black" or "white". The way Glynn chooses to do this is to compute the color intensity, defined as the mean of the RGB triple, and pick "black" (intensity 0) for text color if the background intensity is greater than 127, or "white" (intensity 255) when the background intensity is less than or equal to 127. Sonego calculates 

\[
L = c(0.2, 0.6, 0) \times \frac{\text{col2rgb(color)}}{255}
\]

and returns "black" if \( L \geq 0.2 \) and "white" else.

Value

a vector containing the contrast color (either black or white)

Author(s)

Andri Signorell <andri@signorell.net> based on code of Earl F. Glynn, Stowers Institute for Medical Research, 2004

Examples

# works fine for grays
PlotArea( y=matrix(rep(1, times=3, each=8), ncol=8), x=1:3, 
  col=gray(1:8 / 8), ylab="", xlab="", axes=FALSE )
text( x=2, y=1:8-0.5, levels(d.pizza$driver),
  col=TextContrastColor(gray(1:8 / 8)))

# and not so fine, but still ok, for colors
par(mfrow=c(1,2))
PlotArea( y=matrix(rep(1, times=3, each=12), ncol=12), x=1:3,
  col=rainbow(12), ylab="", xlab="", axes=FALSE, main="method = Glynn" )
text( x=2, y=1:12-0.5, levels(d.pizza$driver),
  col=TextContrastColor(rainbow(12)))

PlotArea( y=matrix(rep(1, times=3, each=12), ncol=12), x=1:3,
  col=rainbow(12), ylab="", xlab="", axes=FALSE, main="method = Sonego" )
text( x=2, y=1:12-0.5, levels(d.pizza$driver),
  col=TextContrastColor(rainbow(12), method="sonego"))
**TextToTable**

*Converts String To a Table*

**Description**

Try to convert a string to a table, by first creating a data.frame using `read.table`. This can then be coerced to a matrix first, and subsequently to a table. The names of the dimensions can be specified.

**Usage**

```
TextToTable(x, dimnames = NULL, ...)
```

**Arguments**

- `x` the string to be interpreted as table.
- `dimnames` the names of the dimensions.
- `...` the dots will be passed to the function `read.table` and can be used for example to specify `header`, `sep` and `row.names` arguments.

**Value**

a table

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

`read.table`, `as.table`, `as.matrix`

**Examples**

```
txt <- "Democrat, Independent, Republican
M, 762, 327, 468
F, 484, 239, 477"

(tab <- TextToTable(txt, header=TRUE, sep="","", dimnames=c("gender", "party")))
```
**TheilU**

*Theil's U Index of Inequality*

**Description**

Calculate Theil's U index of inequality.

**Usage**

```r
TheilU(a, p, type = c(2, 1), na.rm = FALSE)
```

**Arguments**

- `a`
  - a numeric vector with the actual observed values.
- `p`
  - a numeric vector containing the predictions.
- `type`
  - defining the type of Theil's two U measures, see Details. Default is 2.
- `na.rm`
  - logical, indicating whether NA values should be stripped before the computation proceeds. If set to TRUE complete cases of cbind(x,y) will be used. Defaults to FALSE.

**Details**

Theil proposed two error measures, but at different times and under the same symbol U, which has caused some confusion. U type = 1 is taken from Theil (1958, pp. 31-42). The argument `a` represents the actual observations and `p` the corresponding predictions. He left it open whether `a` and `p` should be used as absolute values or as observed and predicted changes. Theil (1966, chapter 2) proposed U type = 2 as a measure of forecast quality: "...where $A_i$ and $P_i$ stand for a pair of predicted and observed changes. ..."

As $U_1$ has some serious disadvantages (see Bliemel 1973) it is recommended to use $U_2$.

`Gini`
The function can be used to add a title to a plot surrounded by a rectangular box. This is useful for plotting several plots in narrow distances.

Usage

TitleRect(label, bg = "grey", border = 1, col = "black", xjust = 0.5, line = 2, ...)

Arguments

- label: the main title
- bg: the background color of the box.
- border: the border color of the box
- col: the font color of the title
- xjust: the x-justification of the text. This can be c(0, 0.5, 1) for left, middle- and right alignment.
- line: on which MARgin line, starting at 0 counting outwards
- ... the dots are passed to the text function, which can be used to change font and similar arguments.

Value

nothing is returned

TitleRect("pressure")
TMod

Comparison Table For Linear Models

Description
Collect the coefficients and some qualifying statistics of linear models and organize it in a table for comparison and reporting. The function supports linear and general linear models.

Usage
TMod(..., FUN = NULL)
ModSummary(x, ...)

## S3 method for class 'lm'
ModSummary(x, conf.level = 0.95, ...)

## S3 method for class 'glm'
ModSummary(x, conf.level = 0.95, ...)

## S3 method for class 'TMod'
plot(x, terms = NULL, intercept = FALSE, ...)

Arguments

x
a (general) linear model object.

...a list of (general) linear models.

conf.level
the level for the confidence intervals.

FUN
function with arguments est, se, tval, pval, lci, uci to display the coefficients. The default function will display the coefficient and significance stars for the p-values.

terms
a vector with the terms of the model formula to be plotted. By default this will be all of them.

intercept
logical, defining whether the intercept should be plotted (default is FALSE).

Details
In order to compare the coefficients of linear models, the user is left to his own devices. R offers no support in this respect. TMod() jumps into the breach and displays the coefficients of several models in tabular form. For this purpose, different quality indicators for the models are displayed, so that a comprehensive comparison of the models is possible. In particular, it is easy to see the effect that adding or omitting variables has on forecast quality.

A plot function for a TMod object will produce a dotchart with the coefficients and their confidence intervals.
**Value**

character table

ToLong, ToWide

Reshape a Vector From Long to Wide Shape Or Vice Versa

Description

Simple reshaping a vector from long to wide or from wide to long shape by means of a single factor.

Usage

ToLong(x, varnames = NULL)
ToWide(x, g, by = NULL, varnames = NULL)

Arguments

x the vector to be reshaped
g the grouping vector to be used for the new columns. The resulting data.frame will return one column per grouplevel.
by a vector to be used to merge the pieces of x. If this is left to NULL the pieces will be merged by rownames in the order they are supplied.
varnames the variable names if not the grouping levels should be used.

Details

ToLong expects x as a matrix or a data.frame and reshapen it to a (long) factor representation. ToWide expects the vectors x, g, by, whereas x being the variable, g the splitting factor and by a vector for rowwise merging.

Value

the reshaped object
TOne

Author(s)

Andri Signorell <andri@signorell.net>

reshape

Examples

d.x <- read.table(header=TRUE, text="
AA BB CC DD EE FF GG
7.9 18.1 13.3 6.2 9.3 8.3 10.6
9.8 14.0 13.6 7.9 2.9 9.1 13.0
6.4 17.4 16.0 10.9 8.6 11.7 17.5
")

ToLong(d.x)

# ToWide by row numbers (by = NULL)
ToWide(PlantGrowth$weight, PlantGrowth$group)

# To wide aligned by key
set.seed(41)
PlantGrowth$nr <- c(sample(12, 10), sample(12, 10), sample(12, 10))
head(PlantGrowth)

ToWide(PlantGrowth$weight, PlantGrowth$group, by=PlantGrowth$nr)

TOne

Create Table One Describing Baseline Characteristics

Description

Create a table summarizing continuous, categorical and dichotomous variables, optionally stratified
by one or more variables, while performing adequate statistical tests.

Usage

TOne(x, grp = NA, add.length = TRUE, colnames = NULL, vnames = NULL, total = TRUE,
align = \"l\", FUN = NULL, TEST = NULL, intref = "high",
fmt.pval = as.fmt(fmt = "*", na.form = " "))

Arguments

x
a data.frame containing all the variables to be included in the table.

grp
the grouping variable.

add.length
logical. If set to TRUE (default), a row with the lengths of the group will be
inserted as first row of the table.
colnames       a vector of columnnames for the result table.

vnames         a vector of variablenames to be placed in the first column instead of the real names.

total          logical, TRUE if totals should be added.

align          the character on whose position the strings will be aligned. Left alignment can be requested by setting sep = "\l", right alignment by "\r" and center alignment by "\c". Mind the backslashes, as if they are omitted, strings would be aligned to the character l, r or c respectively. Default value is "\l", thus left alignment.

FUN             the function to be used as location and dispersion measure (typically mean/sd or alternatively median/IQR). See examples.

TEST           a list of functions to be used to test the variables. Must be named as "num", "cat" and "dich" and be defined as function with arguments (x,g), generating something similar to a p.value. (See examples.)

intref          one out of "high" (default) or "low", defining which value of a dichotomous numeric or logical variable should be reported. Usually this will be 1 or TRUE. Setting it to "low" will report the lower value 0 or FALSE.

fmt.pval         format code or function for the p-values of the tests, default is as.fmt(fmt="p",na.form="")

Details

There are three types of variables currently implemented: numeric, factor and variables with only two levels.

Value

a character matrix

## Not run: -- Send the whole stuff to Word

wrd <- GetNewWrd()
ToWrd(TOne(x = d.pizza[, c("temperature","delivery_min","driver","wine_ordered")],
       grp=d.pizza$quality))

## End(Not run)
**Description**

Send objects like tables, ftabels, lm tables, TOnes or just simple texts to a MS-Word document.

**Usage**

```r
ToWrd(x, font = NULL, ..., wrd = DescToolsOptions("lastWord"))

## S3 method for class 'Freq'
ToWrd(x, font = NULL, main = NULL, ..., wrd = DescToolsOptions("lastWord"))

## S3 method for class 'table'
ToWrd(x, font = NULL, main = NULL, align = NULL,
      tablestyle = NULL, autofit = TRUE,
      row.names = FALSE, col.names = TRUE, ..., wrd = DescToolsOptions("lastWord"))

## S3 method for class 'data.frame'
ToWrd(x, font = NULL, main = NULL, row.names = NULL, ...,
      wrd = DescToolsOptions("lastWord"))

## S3 method for class 'ftable'
ToWrd(x, font = NULL, main = NULL, align = NULL,
      method = "compact", ..., wrd = DescToolsOptions("lastWord"))

## S3 method for class 'TOne'
ToWrd(x, font = NULL, para = NULL, main = NULL, align = NULL,
      autofit = TRUE, ..., wrd = DescToolsOptions("lastWord"))

## S3 method for class 'lm'
ToWrd(x, font = NULL, ..., wrd = DescToolsOptions("lastWord"))

## S3 method for class 'character'
ToWrd(x, font = NULL, para = NULL, style = NULL, bullet = FALSE,
      ..., wrd = DescToolsOptions("lastWord"))

## Default S3 method:
ToWrd(x, font = NULL, ..., wrd = DescToolsOptions("lastWord"))
```

**Arguments**

- `x` the object to be transferred to Word.
- `font` the font to be used to the output. This should be defined as a list containing fontname, fontsize, bold and italic flags: list(name="Arial",size=10,bold=FALSE,italic=TRUE).
- `para` list containing paragraph format properties to be applied to the inserted text. For right align the paragraph one can set: list(alignment="r",LineBefore=0.5). See details for the full set of properties.
a caption for a table. This will be inserted by \texttt{WrdCaption} in Word and can be listed afterwards in a specific index. Default is \texttt{NULL}, which will insert nothing. Ignored if \texttt{x} is not a table.

character vector giving the alignment of the table columns. "l" means left, "r" right and "c" center alignment. The code will be recycled to the length of the number of columns.

string specifying how the "ftable" object is formatted (and printed if used as in \texttt{write.ftable()} or the \texttt{print} method). Can be abbreviated. Available methods are (see the examples):

- "non.compact" the default representation of an "ftable" object.
- "row.compact" a row-compact version without empty cells below the column labels.
- "col.compact" a column-compact version without empty cells to the right of the row labels.
- "compact" a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string \texttt{lsep}.

logical, defining if the columns of table should be fitted to the length of their content.

logical, defining whether the row.names should be included in the output. Default is \texttt{FALSE}.

logical, defining whether the col.names should be included in the output. Default is \texttt{TRUE}.

either the name of a defined Word tablestyle or its index.

character, name of a style to be applied to the inserted text.

further arguments to be passed to or from methods.

logical, defines if the text should be formatted as bullet points.

the pointer to a word instance. Can be a new one, created by \texttt{GetNewWrd()} or an existing one, created by \texttt{GetCurrWrd()}. Default is the last created pointer stored in \texttt{DescToolsOptions("lastWord")}.

The paragraph format can be defined by means of these properties:

- \texttt{LeftIndent, RightIndent, SpaceBefore, SpaceBeforeAuto, SpaceAfter, SpaceAfterAuto, LineSpacingRule, Alignment, WidowControl, KeepWithNext, KeepTogether, PageBreakBefore, NoLineNumber, Hyphenation, FirstLineIndent, OutlineLevel, CharacterUnitLeftIndent, CharacterUnitRightIndent, CharacterUnitFirstLineIndent, LineUnitBefore, LineUnitAfter, MirrorIndents}.

if \texttt{x} is a table a pointer to the table will be returned

```r
## Not run:
# we can't get this through the CRAN test - run it with copy/paste to console

wrd <- GetNewWrd()
ToWrd("This is centered Text in Arial Black\n", 
   para=list(Alignment=wdConst$wdAlignParagraphCenter, 
     SpaceBefore=3, SpaceAfter=6), 
   font=list(name="Arial Black", size=14), 
   wrd=wrd)

sel <- wrd$Selection()$Borders(wdConst$wdBorderBottom)
sel[["LineStyle"]]<- wdConst$wdLineStyleSingle

t1 <- TOne(x = d.pizza[, c("temperature","delivery_min","driver","wine_ordered")], 
   grp=d.pizza$wine_delivered)
ToWrd(t1, font=list(name="Algerian"), wrd=wrd)

tab <- table(d.pizza$driver, d.pizza$area)
ToWrd(tab, font = list(size=15, name="Arial"), row.names = TRUE, col.names = TRUE, 
      main="my Title", wrd=wrd)
ToWrd(tab, font = list(size=10, name="Arial narrow"), 
      row.names = TRUE, col.names=FALSE, wrd=wrd)
ToWrd(tab, font = list(size=15, name="Arial"), align="r", 
      row.names = FALSE, col.names=TRUE, wrd=wrd)
ToWrd(tab, font = list(size=15, name="Arial"), 
      row.names = FALSE, col.names=FALSE, wrd=wrd)
ToWrd(tab, tablestyle = "Mittlere Schattierung 2 - Akzent 4", 
      row.names=TRUE, col.names=TRUE, wrd=wrd)
ToWrd(Format(tab, big.mark = "\n"); digits=0), wrd=wrd)

zz <- ToWrd(Format(tab, big.mark = "\n"); digits=0), wrd=wrd)
zz$Rows(1)$Select()
WrdFont(wrd = wrd) <- list(name="Algerian", size=14, bold=TRUE)

## End(Not run)
```
Description
Send objects like tables, ftables, lm tables, TOnes or just simple texts to a MS-Word document and place a bookmark on them. This has the advantage, that objects in a Word document can be updated later, provided the bookmark name has been stored.

Usage

```r
ToWrdB(x, font = NULL, ..., wrd = DescToolsOptions("lastWord"),
   bookmark = gettextf("bmt%s", round(runif(1, min = 0.1) * 1e+09)))
```

Arguments

- `x`: the object to be transferred to Word.
- `font`: the font to be used to the output. This should be defined as a list containing fontname, fontsize, bold and italic flags: list(name="Arial",size=10,bold=FALSE,italic=TRUE).
- `...`: further arguments to be passed to or from methods.
- `wrd`: the pointer to a word instance. Can be a new one, created by `GetNewWrd()` or an existing one, created by `GetCurrWrd()`. Default is the last created pointer stored in `DescToolsOptions("lastWord")`.
- `bookmark`: the name of the bookmark.

Details
This function encapsulates `ToWrd`, by placing a bookmark over the complete inserted results. The given name can be questioned with `bm$name()`.

Value

a handle to the set bookmark

Author(s)
Andri Signorell <andri@signorell.net>

`ToWrd`, `WrdInsertBookmark`

Examples

```r
## Not run:
# we can't get this through the CRAN test - run it with copy/paste to console
wrd <- GetNewWrd()
bm <- ToWrdB("This is text to be possibly replaced later.")

# get the automatically created name of the bookmark
bm$name()
```
ToWrdPlot

Send a Plot to Word and Bookmark it

Description

Evaluate given plot code to a \texttt{tiff()} device and imports the created plot in the currently open MS-Word document. The imported plot is marked with a bookmark that can later be used for a potential update (provided the bookmark name has been stored).

Usage

\begin{verbatim}
ToWrdPlot(plotcode, width = NULL, height = NULL, scale = 100, res = 300, crop = 0, title = NULL, wrd = DescToolsOptions("lastWord"), bookmark = gettextf("bmp\%s", round(runif(1, min = 0.1) * 1e+09)))
\end{verbatim}

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plotcode</td>
<td>code chunk needed for producing the plot</td>
</tr>
<tr>
<td>bookmark</td>
<td>character, the name of the bookmark</td>
</tr>
<tr>
<td>width</td>
<td>the width in cm of the plot in the Word document (default 15)</td>
</tr>
<tr>
<td>height</td>
<td>the height in cm of the plot in the Word document (default 9.3)</td>
</tr>
<tr>
<td>scale</td>
<td>the scale of the plot (default 100)</td>
</tr>
<tr>
<td>res</td>
<td>the resolution for the graphic (default 300)</td>
</tr>
<tr>
<td>crop</td>
<td>a vector of 4 elements, the crop factor for all 4 sides of a picture in cm (default all 0)</td>
</tr>
<tr>
<td>title</td>
<td>character, the title of the plot to be inserted in the word document</td>
</tr>
<tr>
<td>wrd</td>
<td>the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions(&quot;lastWord&quot;).</td>
</tr>
</tbody>
</table>

Details

An old and persistent problem that has existed for a long time is that as results once were loaded into a Word document the connection broke so that no update was possible. It was only recently that I realized that bookmarks in Word could be a solution for this. The present function evaluates some given plot code chunk using a \texttt{tiff} device and imports the created plot in a word document. The imported plot is given a bookmark, that can be used afterwards for changing or updating the plot.
This function is designed for use with the `DescToolsAddIns` functions `ToWrdPlotWithBookmark()` and `ToWrdWithBookmark()` allowing to assign keyboard shortcuts. The two functions will also insert the newly defined bookmark in the source file in a format, which can be interpreted by the function `UpdateBookmark()`.

**Value**

- a list
  - `plot_hwnd` a windows handle to the inserted plot
  - `bookmark` a windows handle to the bookmark

**Author(s)**

# get the automatically created name of the bookmark
bm$name()
WrdGoto(bm$name())
UpdateBookmark(...)  
## End(Not run)
```

---

### Trim

**Trim a Vector**

**Description**

Clean data by means of trimming, i.e., by omitting outlying observations.

**Usage**

```r
Trim(x, trim = 0.1, na.rm = FALSE)
```
Arguments

- **x**: a numeric vector to be trimmed.
- **trim**: the fraction (0 to 0.5) of observations to be trimmed from each end of x. Values of trim outside that range (and < 1) are taken as the nearest endpoint. If trim is set to a value >1 it’s interpreted as the number of elements to be cut off at each tail of x.
- **na.rm**: a logical value indicating whether NA values should be stripped before the computation proceeds.

Details

A symmetrically trimmed vector \(x\) with a fraction of trim observations (resp. the given number) deleted from each end will be returned. If trim is set to a value >0.5 or to an integer value > \(n/2\) then the result will be NA.

Value

The trimmed vector \(x\). The indices of the trimmed values will be attached as attribute named "trim".

Note

This function is basically an excerpt from the base function `mean`, which allows the vector \(x\) to be trimmed before calculating the mean. But what if a trimmed standard deviation is needed?

Author(s)

R-Core (function mean), Andri Signorell <andri@signorell.net>

```
Student's t-Test Based on Sample Statistics

Description
Performs one and two sample t-tests based on user supplied summary information instead of data as in t.test().

Usage
TTestA(mx, sx, nx, my = NULL, sy = NULL, ny = NULL,
alternative = c("two.sided", "less", "greater"),
mu = 0, paired = FALSE, var.equal = FALSE,
conf.level = 0.95, ...)

Arguments
mx a single number representing the sample mean of x.
my an optional single number representing the sample mean of y.
sx a single number representing the sample standard deviation of x.
sy an optional single number representing the sample standard deviation of y.
nx a single number representing the sample size of x.
ny an optional single number representing the sample size of y.
alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
mu a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
paired paired = TRUE is not supported here and only present for consistency of arguments. Use one-sample-test for the differences instead.
var.equal a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.
conf.level confidence level of the interval.
... further arguments to be passed to or from methods.

Details
alternative = "greater" is the alternative that x has a larger mean than y.
If paired is TRUE then both mx, sx and my, sy must be specified and nx must be equal to ny. If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.
If the input data are effectively constant (compared to the larger of the two means) an error is generated.
Value

A list with class "htest" containing the following components:

- **statistic**: the value of the t-statistic.
- **parameter**: the degrees of freedom for the t-statistic.
- **p.value**: the p-value for the test.
- **conf.int**: a confidence interval for the mean appropriate to the specified alternative hypothesis.
- **estimate**: the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.
- **null.value**: the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: a character string indicating what type of t-test was performed.
- **data.name**: a character string giving the name(s) of the data.

See Also

t.test

Examples

```r
## Classical example: Student's sleep data
mx <- 0.75
my <- 2.33
sx <- 1.789010
sy <- 2.002249
nx <- ny <- 10
TTestA(mx=mx, my=my, sx=sx, sy=sy, nx=nx, ny=ny)

# compare to
with(sleep, t.test(extra[group == 1], extra[group == 2]))

# use the one sample test for the differences instead of paired=TRUE option
x <- with(sleep, extra[group == 1])
y <- with(sleep, extra[group == 2])
TTestA(mx=mean(x-y), sx=sd(x-y), nx=length(x-y))

# compared to
t.test(x, y, paired = TRUE)
```
TukeyBiweight

Calculate Tukey’s Biweight Robust Mean

Description

This calculates a robust average that is unaffected by outliers.

Usage

TukeyBiweight(x, const = 9, na.rm = FALSE, conf.level = NA, ci.type = "bca", R = 1000, ...)

Arguments

- **x**: a numeric vector
- **const**: a constant. *const* is preassigned a value of 9 according to the Cook reference below but other values are possible.
- **na.rm**: logical, indicating whether NA values should be stripped before the computation proceeds. Defaults to FALSE.
- **conf.level**: confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
- **ci.type**: The type of confidence interval required. The value should be any subset of the values “basic”, “stud”, “perc”, “bca” or simply “all” which will compute all four types of intervals.
- **R**: The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case *R* would be a vector of integers where each component gives the number of resamples from each of the rows of weights.
- **...**: the dots are passed to the function `boot`, when confidence intervals are calculated.

Details

This is a one step computation that follows the Affy whitepaper below, see page 22. *const* determines the point at which outliers are given a weight of 0 and therefore do not contribute to the calculation of the mean. *const = 9* sets values roughly +/-6 standard deviations to 0. *const = 6* is also used in tree-ring chronology development. Cook and Kairiukstis (1990) have further details.

An exact summation algorithm (Shewchuk 1997) is used. When some assumptions about the rounding of floating point numbers and conservative compiler optimizations hold, summation error is completely avoided. Whether the assumptions hold depends on the platform, i.e. compiler and CPU.

Value

A numeric mean.
TwoGroups

---

**TwoGroups**

Describe a Variable by a Factor with Two Levels

Description
This function describes a numeric variable by a grouping factor with two levels. First, a descriptive text listing the frequencies and means of the two groups and the results of the significance test is generated. The results of `Desc(x~g)` are reported as they are provided by the function, followed by a plot consisting of a density plot and a box plot. This description makes sense, for example, if the age distribution of a collective is to be represented for both sexes.

Usage
`
TwoGroups(x, g, test = t.test, main = NULL, 
          font.txt = NULL, font.desc = NULL, wrd = NULL, ...)
`

Arguments
- **x**: the numeric variable to describe.
- **g**: the grouping factor (preferably with two levels.)
- **test**: the test to be applied, default is `t.test()`.
- **main**: the main title.
- **font.txt**: the font chosen for the introducing text, when sending the output to Word.
- **font.desc**: the font chosen for the description, when sending the output to Word.
the pointer to a running MS Word instance, as created by GetNewWrd() (for a new one) or by GetCurrWrd() for an existing one. Default is NULL, which will report all results to the console.

the dots are sent to the internally used function Phrase(). They can be used to choose the language (lang) or provide variable name (xname).

Value

list with the results calculated by the used functions

Author(s)

Andri Signorell <andri@signorell.net>

See Also

Desc, PlotMultiDens, Phrase

Examples

```r
x <- d.pizza$temperature
g <- factor(d.pizza$rabate)

# we can change the colors for the plot by setting the DescToolsOptions
DescToolsOptions(col=c(horange, hgreen))
TwoGroups(x, g, main="Temperature ~ Rebate")

# for an output to Word simply define the wrd argument
# wrd <- GetNewWrd()
# TwoGroups(x, g, font.desc=list(name="Consolas", size=8),
# main="Temperature ~ Rebate", wrd=wrd)
```

---

**UncertCoef**

**Uncertainty Coefficient**

**Description**

The uncertainty coefficient $U(C|R)$ measures the proportion of uncertainty (entropy) in the column variable $Y$ that is explained by the row variable $X$. The function has interfaces for a table, a matrix, a data.frame and for single vectors.

**Usage**

```r
UncertCoef(x, y = NULL, direction = c("symmetric", "row", "column"),
conf.level = NA, p.zero.correction = 1/sum(x)^2, ...)
```
Arguments

x  a numeric vector, a factor, matrix or data frame.
y  NULL (default) or a vector, an ordered factor, matrix or data frame with compatible dimensions to x.
direction  direction of the calculation. Can be "row" (default) or "column", where "row" calculates UncertCoef (RIC) ("column dependent").
conf.level  confidence level of the interval. If set to NA (which is the default) no confidence interval will be calculated.
p.zero.correction  slightly nudge zero values so that their logarithm can be calculated
...  further arguments are passed to the function table, allowing i.e. to set useNA. This refers only to the vector interface.

Details

The uncertainty coefficient is computed as

$$U(C|R) = \frac{H(X) + H(Y) - H(XY)}{H(Y)}$$

and ranges from [0, 1].

Value

Either a single numeric value, if no confidence interval is required, or a vector with 3 elements for estimate, lower and upper confidence interval.

Author(s)

Andri Signorell <andri@signorell.net> strongly based on code from Antti Arppe <antti.arppe@helsinki.fi>

---

### Description

The function `unirootAll` searches the interval from lower to upper for several roots (i.e., zero’s) of a function `f` with respect to its first argument.

### Usage

```r
unirootAll(f, interval, lower = min(interval), upper = max(interval),
            tol = .Machine$double.eps^0.2, maxiter = 1000, n = 100, ...)
```

### Arguments

- `f` the function for which the root is sought.
- `interval` a vector containing the end-points of the interval to be searched for the root.
- `lower` the lower end point of the interval to be searched.
- `upper` the upper end point of the interval to be searched.
- `tol` the desired accuracy (convergence tolerance).
- `maxiter` the maximum number of iterations.
- `n` number of subintervals in which the root is sought.
- `...` additional named or unnamed arguments to be passed to `f` (but beware of partial matching to other arguments).

### Details

- `f` will be called as `f(x,...)` for a numeric value of `x`.
- Run `demo(Jacobandroots)` for an example of the use of `unirootAll` for steady-state analysis.
- See also second example of `gradient` This example is discussed in the book by Soetaert and Herman (2009).

### Value

- a vector with the roots found in the interval

### Note

- This is a verbatim copy from rootSolve::uniroot.all (v. 1.7).
Note

The function calls `uniroot`, the basic R-function.

It is not guaranteed that all roots will be recovered.

This will depend on \( n \), the number of subintervals in which the interval is divided.

If the function "touches" the X-axis (i.e. the root is a saddle point), then this root will generally not be retrieved. (but chances of this are pretty small).

Whereas `unitroot` passes values one at a time to the function, `UnirootAll` passes a vector of values to the function. Therefore \( f \) should be written such that it can handle a vector of values. See last example.

Author(s)

Karline Soetaert <karline.soetaert@nioz.nl>

See Also

`uniroot` for more information about input.

Examples

```r
## Mathematical examples

# a well-behaved case...
fun <- function (x) cos(2*x)^3
curve(fun(x), 0, 10, main = "UnirootAll")
All <- UnirootAll(fun, c(0, 10))
points(All, y = rep(0, length(All)), pch = 16, cex = 2)

# a difficult case...
f <- function (x) 1/cos(1+x^2)
AA <- UnirootAll(f, c(-5, 5))
curve(f(x), -5, 5, n = 500, main = "UnirootAll")
points(AA, rep(0, length(AA)), col = "red", pch = 16)
f(AA)  # !!!!

## Vectorisation:

# from R-help Digest, Vol 130, Issue 27
integrand1 <- function(x) 1/x*dnorm(x)
integrand2 <- function(x) 1/(2*x-50)*dnorm(x)
integrand3 <- function(x, C) 1/(x+C)
```
res <- function(C) {
  integrate(integrand1, lower = 1, upper = 50)$value +
  integrate(integrand2, lower = 50, upper = 100)$value -
  integrate(integrand3, C = C, lower = 1, upper = 100)$value
}

# uniroot passes one value at a time to the function, so res can be used as such
uniroot(res, c(1, 1000))

# Need to vectorise the function to use UnirootAll:
res <- Vectorize(res)
UnirootAll(res, c(1, 1000))

---

**Untable**

**Recover Original Data From Contingency Table**

**Description**

Recreates the data.frame out of a contingency table x.

**Usage**

```
Untable(x, ...)
```

## S3 method for class 'data.frame'

```
Untable(x, freq = "Freq", rownames = NULL, ...)
```

## Default S3 method:

```
Untable(x, dimnames = NULL, type = NULL, rownames = NULL, colnames = NULL, ...)
```

**Arguments**

- **x**
  - a numeric vector, a matrix, a table or a data.frame. If x is a vector, a matrix or a table it is interpreted as frequencies which are to be inflated to the original list. If x is a data.frame it is interpreted as a table in frequency form (containing one or more factors and a frequency variable).

- **dimnames**
  - the dimension names of x to be used for expanding. Can be used to expand a weight vector to its original values. If set to NULL (default) the dimnames of x will be used.

- **type**
  - defines the data type generated. This allows to directly define factors or ordered factors, but also numeric values. See examples.

- **rownames**
  - A names vector for the rownames of the resulting data.frame. If set to NULL (default) the names will be defined according to the table’s dimnames.
colnames  A names vector for the colnames of the resulting data.frame. If set to NULL (default) the names will be defined according to the table’s dimnames.

def  character, the name of the frequency variable in case x is a data.frame.

...  further arguments passed to or from functions (not used here).

Details

For x being a vector this reduces to \texttt{rep(...,n)} with n as vector (which is not supported by \texttt{rep()}). NAs in the table will be treated as 0 without raising an error.

Value

a data.frame with the detailed data (even if x was a 1-dimensional table)

Author(s)

Andri Signorell <andri@signorell.net>

            set2=sample(letters[11:15], size=40, replace=TRUE))
Untable(tab)

# return a numeric vector by setting type and coerce to a vector by [,]
Untable(c(6,2,2), type="as.numeric")[,]

# how to produce the original list based on frequencies, given as a data.frame
d.freq <- data.frame(xtabs(Freq ~ Sex + Survived, data=Titanic))

# a data list with each individual
d.data <- Untable(xtabs(c(1364, 126, 367, 344) ~ .,
                        expand.grid(levels(d.freq$Sex),levels(d.freq$Survived))))
head(d.data)

# expand a weights vector
Untable(c(1,4,5), dimnames=list(c("Zurich","Berlin","London")))
Unwhich

# and the same with a numeric vector
Untable(c(1,4,5), dimnames=list(c(5,10,15)), type="as.numeric")[,] # ... which again is nothing else than
rep(times=c(1,4,5), x=c(5,10,15))

# the data.frame interface
d.freq <- data.frame(f1=c("A","A","B","B"), f2=c("C","D","C","D"), Freq=c(1,2,3,4))
Untable(d.freq)

---

### Unwhich

#### Inverse Which

**Description**

The inverse function to `which` creates a logical vector/matrix from indices.

**Usage**

`Unwhich(idx, n, useNames = TRUE)`

**Arguments**

- `idx` the indices as returned by `which`.
- `n` integer, the length of the original vector.
- `useNames` logical, determining if the names of the indices should be preserved.

**Value**

a logical vector of the length n, with TRUE on the positions i.

**Author(s)**

Nick Sabbe

**References**

http://stackoverflow.com/questions/7659833/inverse-of-which

**See Also**

`which`

**Examples**

```r
ll <- c(TRUE, FALSE, TRUE, NA, FALSE, FALSE, TRUE)
names(ll) <- letters[seq(ll)]
i <- which(ll)
# back again (loosing the names of the FALSEs)
Unwhich(i, length(ll))
```
VanWaerdenTest  

van der Waerden Test

Description

Performs a van der Waerden normal scores test.

Usage

VanWaerdenTest(x, ...)

## Default S3 method:
VanWaerdenTest(x, g, ...)

## S3 method for class 'formula'
VanWaerdenTest(formula, data, subset, na.action, ...)

Arguments

x
a numeric vector of data values, or a list of numeric data vectors. Non-numeric elements of a list will be coerced, with a warning.

g
a vector or factor object giving the group for the corresponding elements of x. Ignored with a warning if x is a list.

formula
a formula of the form response ~ group where response gives the data values and group a vector or factor of the corresponding groups.

data
an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset
an optional vector specifying a subset of observations to be used.

na.action
a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

...
further arguments to be passed to or from methods.

Details

VanWaerdenTest performs a van der Waerden test of the null that the location parameters of the distribution of x are the same in each group (sample). The alternative is that they differ in at least one.

The van der Waerden rank scores are defined as the ranks of data, i.e., \( R[i], i = 1, 2, ..., n \), divided by \( 1 + n \) transformed to a normal score by applying the inverse of the normal distribution function, i.e., \( \Phi^{-1}(R[i]/(1 + n)) \). The ranks of data are obtained by ordering the observations from all groups (the same way as kruskal.test does it).

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use VanWaerdenTest(x) to perform the test. If the samples are not yet contained in a list, use VanWaerdenTest(list(x, ...)).
Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list with class "htest" containing the following components:

 statistic the van der Waerden statistic.
 parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic.
 p.value the p-value of the test.
 method the character string "van-der-Waerden normal scores test".
 data.name a character string giving the names of the data.

References

See Also

 normal_test in package coin where the test is implemented in a more general context (but has a quite unpractical interface).

Examples

## Hollander & Wolfe (1973), 116.
## Mucociliary efficiency from the rate of removal of dust in normal
## subjects, subjects with obstructive airway disease, and subjects
## with asbestosis.
## x <- c(2.9, 3.0, 2.5, 2.6, 3.2) \# normal subjects
## y <- c(3.8, 2.7, 4.0, 2.4) \# with obstructive airway disease
## z <- c(2.8, 3.4, 3.7, 2.2, 2.0) \# with asbestosis

VanWaerdenTest(list(x, y, z))

## Equivalently,
## x <- c(x, y, z)
## g <- factor(rep(1:3, c(5, 4, 5)),
## labels = c("Normal subjects",
## "Subjects with obstructive airway disease",
## "Subjects with asbestosis"))

VanWaerdenTest(x, g)

## Formula interface.
require(graphics)
boxplot(Ozone ~ Month, data = airquality)
VanWaerdenTest(Ozone ~ Month, data = airquality)
## Description

Var() computes the variance of x. If x is a matrix variances of the columns of x are computed.

## Usage

Var(x, ...)

### S3 method for class 'Freq'
Var(x, breaks, ...)

### Default S3 method:
Var(x, weights = NULL, na.rm = FALSE, method = c("unbiased", "ML"), ...)

## Arguments

- **x**: a numeric vector, matrix or data frame.
- **weights**: a numerical vector of weights the same length as x giving the weights to use for elements of x.
- **na.rm**: logical. Should missing values be removed?
- **method**: determines the estimator type; if "unbiased" (the default) then the usual unbiased estimate (using Bessel's correction) is returned, if "ML" then it is the maximum likelihood estimate for a Gaussian distribution. Uses stats:cov.wt for both methods.
- **breaks**: breaks for calculating the variance for classified data as composed by Freq.
- **...**: further arguments passed to or from other methods.

## Details

Var is just another interface to Cov.

The denominator n − 1 is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return NA when there is only one observation (whereas S-PLUS has been returning NaN), and fail if x has length zero.

## Value

For r <-Cor(*, use = "all.obs"), it is now guaranteed that all(abs(r) <= 1).

## References

See Also
  - `cor`, `cov` for covariance and correlation matrices
  - `cor.test` for confidence intervals (and tests).
  - `cov.wt` for weighted covariance computation.
  - `sd` for standard deviation (vectors).

Examples

```r
Var(1:10)  # 9.166667
Var(1:5, 1:5) # 2.5

# weighted Variance
set.seed(45)
(z <- as.numeric(names(w <- table(x <- sample(-10:20, size=50, replace=TRUE)))))
Var(z, w=w)

# check!
all.equal(Var(x), Var(z, w=w))

# Variance for frequency tables
Var(Freq(as.table(c(6,16,24,25,17))),
    breaks=c(0, 10, 20, 30, 40, 50))
```

---

### VarCI

**Confidence Intervals for the Variance**

**Description**

Calculates confidence intervals for the variance. Available approaches are the classical one using the ChiSquare distribution, a more robust version proposed by Bonett and the bootstrap options available in the package `boot`.

**Usage**

```r
VarCI(x, method = c("classic", "bonett", "norm", "basic", "stud", "perc", "bca"),
    conf.level = 0.95, sides = c("two.sided", "left", "right"),
    na.rm = FALSE, R = 999)
```

**Arguments**

- `x` a (non-empty) numeric vector of data values.
- `method` vector of character strings representing the type of intervals required. The value should be any subset of the values "classic", "bonett", "norm", "basic", "stud", "perc", "bca". See `boot.ci`.
VarCI

conf.level  confidence level of the interval.
sides  a character string specifying the side of the confidence interval, must be one of "two.sided" (default), "left" or "right". You can specify just the initial letter. "left" would be analogue to a hypothesis of "greater" in a t.test.
na.rm  logical. Should missing values be removed? Defaults to FALSE.
R  number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case R would be a vector of integers where each component gives the number of resamples from each of the rows of weights. See boot.

Details

The confidence interval for the variance is very sensitive to non-normality in the data. Bonett (2006) has proposed an interval that is nearly exact when the data is normally distributed and provides good performance for moderately non-normal data. See the references for the details.

Value

a numeric vector with 3 elements:

var  variance
lwr.ci  lower bound of the confidence interval
upr.ci  upper bound of the confidence interval

VarTest  

ChiSquare Test for One Variance and F Test to Compare Two Variances

Description

Performs either a one sample ChiSquare test to compare the variance of a vector with a given value or an F test to compare the variances of two samples from normal populations.

Usage

VarTest(x, ...)

## Default S3 method:
VarTest(x, y,
    alternative = c("two.sided", "less", "greater"),
    ratio = 1, sigma.squared = 1,
    conf.level = 0.95, ...)

## S3 method for class 'formula'
VarTest(formula, data, subset, na.action, ...)

Arguments

x, y numeric vectors of data values.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
ratio the hypothesized ratio of the population variances of x and y.

sigma.squared a number indicating the true value of the variance, if one sample test is requested.

conf.level confidence level for the returned confidence interval.

formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

... further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

The null hypothesis is that the ratio of the variances of the populations from which x and y were drawn, or in the data to which the linear models x and y were fitted, is equal to ratio.

Value

A list with class "htest" containing the following components:

statistic the value of the F test statistic.

parameter the degrees of the freedom of the F distribution of the test statistic.

p.value the p-value of the test.

conf.int a confidence interval for the ratio of the population variances.

estimate the ratio of the sample variances of x and y.

null.value the ratio of population variances under the null.

alternative a character string describing the alternative hypothesis.

method the character string "F test to compare two variances".

data.name a character string giving the names of the data.

Author(s)

Andri Signorell <andri@signorell.net> (One sample test)
Two Sample test and help text from R-Core.

See Also

var.test, bartlett.test for testing homogeneity of variances in more than two samples from normal distributions; ansari.test and mood.test for two rank based (nonparametric) two-sample tests for difference in scale.
Examples

```r
x <- rnorm(50, mean = 0, sd = 2)

# One sample test
VarTest(x, sigma.squared = 2.5)

# Two samples
y <- rnorm(30, mean = 1, sd = 1)
VarTest(x, y)  # Do x and y have the same variance?
VarTest(lm(x ~ 1), lm(y ~ 1))  # The same.
```

VecRot

Vector Rotation (Shift Elements)

Description

Shift the elements of a vector in circular mode by k elements to the right (for positive k) or to the left (for negative k), such that the first element is at the (k+1)th position of the new vector and the last k elements are appended to the beginning.

VecShift does not attach the superfluous elements on one side to the other, but fills the resulting gaps with NAs.

Usage

```r
VecRot(x, k = 1)
VecShift(x, k = 1)
```

Arguments

- `x`: a vector of any type.
- `k`: the number of elements to shift.

Details

The function will repeat the vector two times and select the appropriate number of elements from the required shift on.

Value

the shifted vector in the same dimensions as x.

VecShift(letters[1:10], 3)
VecShift(letters[1:10], -3)

VIF

Variance Inflation Factors

Description

Calculates variance-inflation and generalized variance-inflation factors for linear and generalized linear models. It's a measure describing how much the variance of an estimated coefficient is increased because of collinearity.

Usage

VIF(mod)

Arguments

mod an object that responds to coef, vcov, and model.matrix, such as an lm or glm object.

Details

If all terms in an unweighted linear model have 1 df, then the usual variance-inflation factors are calculated.

The vif are defined as

\[ vif_j = \frac{1}{1 - R_j^2} \]

where \( R_j^2 \) equals the coefficient of determination for regressing the explanatory variable \( j \) in question on the other terms in the model. This is one of the well-known collinearity diagnostics.

If any terms in an unweighted linear model have more than 1 df, then generalized variance-inflation factors (Fox and Monette, 1992) are calculated. These are interpretable as the inflation in size of the confidence ellipse or ellipsoid for the coefficients of the term in comparison with what would be obtained for orthogonal data.

The generalized vifs are invariant with respect to the coding of the terms in the model (as long as the subspace of the columns of the model matrix pertaining to each term is invariant). To adjust for the dimension of the confidence ellipsoid, the function also prints \( GVIF^{1/(2 \times df)} \) where \( df \) is the degrees of freedom associated with the term.
Through a further generalization, the implementation here is applicable as well to other sorts of models, in particular weighted linear models and generalized linear models. Values of \( vif \) up to 5 are usually interpreted as uncritical, values above 5 denote a considerable multicollinearity.

**Value**

A vector of \( vifs \), or a matrix containing one row for each term in the model, and columns for the \( GVIF \), \( df \), and \( GVIF^{1/(2 \times df)} \).

**Note**

This is a verbatim copy from the function `car::vif`.

**Author(s)**

Henric Nilsson and John Fox <jfox@mcmaster.ca>

**References**

**Examples**

```r
VIF(lm(Fertility ~ Agriculture + Education, data=swiss))
VIF(lm(Fertility ~ ., data=swiss))
```

---

**Description**

Implements a Vigenere cypher, both encryption and decryption. The function handle keys and text of unequal length and discards non-alphabetic characters.

**Usage**

```r
Vigenere(x, key = NULL, decrypt = FALSE)
```

**Arguments**

- **x** the text to be encrypted
- **key** the key to be used. If this remains to `NULL` the PasswordDlg will be presented and the key can be entered there.
- **decrypt** boolean defining if the text should be encrypted or decrypted.
Details

All characters beside charlist = c(LETTERS, letters, 0:9) will be discarded from the text and from the key.

Value

the encrypted, resp. decrypted text

Author(s)

Andri Signorell <andri@signorell.net>
strongly based on code found at http://rosettacode.org/wiki/Vigen%C3%A8re_cipher#R (credits to the unknown soldier)

Examples

key <- "My FavoriteKey452"
(xenc <- Vigenere("Beware the Jabberwock, my son! The jaws that bite, the claws that catch!", key))

Vigenere(xenc, key, decrypt = TRUE)
# note that everything besides the characters in the list will be discarded

VonNeumannTest

Von Neumann’s Successive Difference Test

Description

A popular statistic to test for independence is the von Neumann ratio.

Usage

VonNeumannTest(x, alternative = c("two.sided", "less", "greater"), unbiased = TRUE)

Arguments

x a numeric vector containing the observations

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

unbiased logical. In order for VN to be an unbiased estimate of the true population value, the calculated value is multiplied by \( \frac{n}{n - 1} \). Default is TRUE.
The VN test statistic is in the unbiased case

\[ VN = \frac{\sum_{i=1}^{n-1} (x_i - x_{i+1})^2 \cdot n}{\sum_{i=1}^{n} (x_i - \bar{x})^2 \cdot (n - 1)} \]

It is known that \((VN - \mu)/\sigma\) is asymptotically standard normal, where \(\mu = \frac{2n}{n-1}\) and \(\sigma^2 = 4 \cdot n^2 \cdot \frac{(n-2)}{(n+1)(n-1)} \cdot \frac{4(n-2)}{(n+1)(n-1)}\).

The VN test statistic is in the original (biased) case

\[ VN = \frac{\sum_{i=1}^{n-1} (x_i - x_{i+1})^2}{\sum_{i=1}^{n} (x_i - \bar{x})^2} \]

The test statistic \((VN - 2)/\sigma\) is asymptotically standard normal, where \(\sigma^2 = \frac{4(n-2)}{(n+1)(n-1)}\).

Missing values are silently removed.

Value

A list with class "htest" containing the components:

- statistic: the value of the VN statistic and the normalized statistic test.
- parameter, n: the size of the data, after the removal of consecutive duplicate values.
- p.value: the p-value of the test.
- alternative: a character string describing the alternative hypothesis.
- method: a character string indicating the test performed.
- data.name: a character string giving the name of the data.

Author(s)

Andri Signorell <andri@signorell.net>

- BartelsRankTest

Examples

VonNeumannTest(d.pizza$temperature)
**Description**

This is a list with all VBA constants for MS Word 2010, which is useful for writing R functions based on recorded macros in Word. This way the constants need not be replaced by their numeric values and can only be complemented with the list’s name, say the VBA-constant `wd10Percent` for example can be replaced by `wdConst$wd10Percent`. A handful constants for Excel are consolidated in `xlConst`.

**Usage**

```r
data(wdConst)
data(xlConst)
```

**Format**

The format is:

- List of 2755
- `$ wd100Words: num -4`
- `$ wd10Percent: num -6`
- `$ wd10Sentences: num -2`
- ...

**Source**

Microsoft

---

**Winsorize**

**Winsorize (Replace Extreme Values by Less Extreme Ones)**

**Description**

Winsorizing a vector means that a predefined quantum of the smallest and/or the largest values are replaced by less extreme values. Thereby the substitute values are the most extreme retained values.

**Usage**

```r
Winsorize(x, minval = NULL, maxval = NULL, probs = c(0.05, 0.95), na.rm = FALSE, type = 7)
```
Arguments

x a numeric vector to be winsorized.
minval the low border, all values being lower than this will be replaced by this value.
The default is set to the 5%-quantile of x.
maxval the high border, all values being larger than this will be replaced by this value.
The default is set to the 95%-quantile of x.
probs numeric vector of probabilities with values in [0,1] as used in quantile.
na.rm should NAs be omitted to calculate the quantiles?
Note that NAs in x are preserved and left unchanged anyway.
type an integer between 1 and 9 selecting one of the nine quantile algorithms detailed in quantile to be used.

Details

The winsorized vector is obtained by

\[
g(x) = \begin{cases} 
-c & \text{for } x \leq -c \\
x & \text{for } |x| < c \\
c & \text{for } x \geq c 
\end{cases}
\]

Consider standardizing (possibly robust) the data before winsorizing.

Value

A vector of the same length as the original data x containing the winsorized data.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

Winsorize from the package robustHD contains an option to winsorize multivariate data
scale, RobScale

Examples

```r
## generate data
set.seed(1234)  # for reproducibility
x <- rnorm(10)  # standard normal
x[1] <- x[1] * 10  # introduce outlier

## Winsorize data
x
Winsorize(x)

# use Large and Small, if a fix number of values should be winsorized (here k=3):
Winsorize(x, minval=tail(Small(x, k=3), 1), maxval=head(Large(x, k=3), 1))
```
WithOptions  

Execute Function with Temporary Options

Description

Setting and resetting options is lengthy in command mode. WithOptions() allows to evaluate a function with temporary set options.

Usage

WithOptions(optlist, expr)

Arguments

optlist  a list with new option settings.
expr  the expression to be evaluated

Value

the function result

Author(s)

Thomas Lumley <t.lumley@auckland.ac.nz>

options,getOption

Examples

# original:
print((1:10)^-1)

# with new options
WithOptions(list(digits=3), print((1:10)^-1))
Woolf Test For Homogeneity in 2x2xk Tables

Description

Test for homogeneity on $2 \times 2 \times k$ tables over strata (i.e., whether the log odds ratios are the same in all strata).

Usage

WoolfTest(x)

Arguments

x a $2 \times 2 \times k$ table, where the last dimension refers to the strata.

Value

A list of class "htest" containing the following components:

- statistic the chi-squared test statistic.
- parameter degrees of freedom of the approximate chi-squared distribution of the test statistic.
- p.value $p$-value for the test.
- method a character string indicating the type of test performed.
- data.name a character string giving the name(s) of the data.
- observed the observed counts.
- expected the expected counts under the null hypothesis.

Note

This function was previously published as woolf_test() in the vcd package and has been integrated here without logical changes.

WoolfTest(migraine)

Description

Accessing bookmarks by name is only possible by browsing the bookmark names. This function returns a handle to a bookmark by name.

Usage

WrdBookmark(bookmark, wrd = DescToolsOptions("lastWord"))

Arguments

bookmark character, the bookmark name
wrd the pointer to a word instance, typically an existing one, created by GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions("lastWord").

Value

a handle to the bookmark

Author(s)

Andri Signorell <andri@signorell.net>

# Now returning the bookmark
bm <- WrdBookmark("mybookmark")

# get the automatically created name of the bookmark
bm$name()

## End(Not run)

---

**WrdCaption**

*Insert Caption to Word*

**Description**

Insert a caption in a given level to a Word document. The caption is inserted at the current cursor position.

**Usage**

WrdCaption(x, index = 1, wrd = DescToolsOptions("lastWord"))

**Arguments**

- **x**: the text of the caption.
- **index**: integer from 1 to 9, defining the number of the heading style.
- **wrd**: the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions("lastWord").

**Author(s)**

Andri Signorell <andri@signorell.net>

## Not run: # Windows-specific example
wrd <- GetNewWrd()

# insert a title in level 1
WrdCaption("My First Caption level 1", index=1, wrd=wrd)

# works as well for several levels
sapply(1:5, function(i)

  WrdCaption(gettextf("My First Caption level %s",i), index=i, wrd=wrd)

)

## End(Not run)
```
Return the Cell Range Of a Word Table

Description

Return a handle of a cell range of a word table. This is useful for formating the cell range.

Usage

WrdCellRange(wtab, from, to)

Arguments

- **wtab**: a handle to the word table as returned i.g. by WrdTable
- **from**: a vector containing row- and column number of the left/upper cell of the cell range.
- **to**: a vector containing row- and column number of the right/lower cell of the cell range.

Details

Cell range selecting might be complicated. This function makes it easy.

Value

- a handle to the range.

- WrdTable

Examples

```r
## Not run:

# Windows-specific example
wrd <- GetNewWrd()
WrdTable(nrow=3, ncol=3, wrd=wrd)
crng <- WrdCellRange(from=c(1,2), to=c(2,3))
crng$Select()

## End(Not run)
```
**WrdFont**  

Get or Set the Font in Word

**Description**

WrdFont can be used to get and set the font in Word for the text to be inserted. WrdFont returns the font at the current cursor position.

**Usage**

```r
WrdFont(wrd = DescToolsOptions("lastWord"))
WrdFont(wrd) <- value
```

**Arguments**

- **value**
  the font to be used to the output. This should be defined as a list containing fontname, fontsize, bold and italic flags:
  ```r
  list(name="Arial",size=10,bold=FALSE,italic=TRUE,color=wdConst$wdColorBlack).
  ```

- **wrd**
  the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions("lastWord").

**Details**

The font color can be defined by a Word constant beginning with wConst$wdColor. The defined colors can be listed with grep("wdColor",names(wdConst),val=TRUE).

**Value**

a list of the attributes of the font in the current cursor position:

- **name**
  the fontname
- **size**
  the fontsize
- **bold**
  bold
- **italic**
  italic
- **color**
  the fontcolor

  ToWrd(gettextf("This is Times size

## End(Not run)
```

### WrdfFormatCells

**WrdFormatCells**

Format Cells Of a Word Table

#### Description

Format cells of a Word table.

#### Usage

```r
WrdFormatCells(wtab, rstart, rend, col = NULL, bg = NULL,
  font = NULL, border = NULL, align = NULL)
```

#### Arguments

- **wtab**: a handle to the word table as returned i.e. by `WrdTable`
- **rstart**: the left/upper cell of the cell range
- **rend**: the right/lower cell of the cell range
- **col**: the foreground colour
- **bg**: the background colour
- **font**: the font to be used to the output. This should be defined as a list containing
  fontname, fontsize, bold and italic flags:
  ```r
  list(name="Arial",size=10,bold=FALSE,italic=TRUE,color=wdConst$wdColorBlack).
  ```
- **border**: the border of the cell range, defined as a list containing arguments for border,
  linestyle, linewidth and color. border is a vector containing the parts of the
  border defined by the Word constants `wdConst$wdBorder...`, being
  `$wdBorderBottom`, `$wdBorderLeft`, `$wdBorderTop`, `$wdBorderRight`, `$wdBorderHorizontal`, `$wdBorderVertical`, `$wdBorderDiagonalUp`, `$wdBorderDiagonalDown`.
  linestyle, linewidth and color will be recycled to the required dimension.
- **align**: a character out of "l", "c", "r" setting the horizontal alignment of the cell range.
**WrdInsertBookmark**

Insert a Bookmark, Goto Bookmark and Update the Text of a Bookmark

**Details**

Cell range selecting might be complicated. This function makes it easy.

**Value**

a handle to the range.

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

WrdTable

**Examples**

```r
## Not run:  # Windows-specific example

m <- matrix(rnorm(12)*100, nrow=4,
             dimnames=list(LETTERS[1:4], c("Variable","Value","Remark")))

wrd <- GetNewWrd()
wt <- ToWrd(m)

WrdFormatCells(wt, rstart=c(3,1), rend=c(4,3),
               bg=wdConst$wdColorGold, font=list(name="Arial Narrow", bold=TRUE),
               align="c", border=list(color=wdConst$wdColorTeal,
                                       linewidth=wdConst$wdLineWidth300pt))

## End(Not run)
```

**Description**

WrdInsertBookmark inserts a new bookmark in a Word document. WrdGotoBookmark allows to set the cursor on the bookmark and WrdUpdateBookmark sets the text within the range of the bookmark.

**Usage**

```r
WrdInsertBookmark(name, wrd = DescToolsOptions("lastWord"))
WrdGoto(name, what = wdConst$wdGoToBookmark, wrd = DescToolsOptions("lastWord"))
WrdUpdateBookmark(name, text, what = wdConst$wdGoToBookmark,
                   wrd = DescToolsOptions("lastWord"))
```
Arguments

- **name**: the name of the bookmark.
- **text**: the text of the bookmark.
- **what**: a word constant, defining the type of object to be used to place the cursor.
- **wrd**: the pointer to a word instance. Can be a new one, created by `GetNewWrd()` or an existing one, created by `GetCurrWrd()`. Default is the last created pointer stored in `DescToolsOptions("lastWord")`.

Details

Bookmarks are useful to build structured documents, which can be updated later.

**WrdMergeCells**

Merges Cells Of a Defined Word Table Range

Description

Merges a cell range of a word table.

Usage

`WrdMergeCells(wtab, rstart, rend)`
Arguments

- `wtab` a handle to the word table as returned i.e. by `WrdTable`
- `rstart` the left/upper cell of the cell range.
- `rend` the right/lower cell of the cell range.

Value

nothing

Author(s)

Andri Signorell <andri@signorell.net>

See Also

`WrdTable`, `WrdCellRange`

Examples

```r
## Not run:

# Windows-specific example
wrd <- GetNewWrd()
wtab <- WrdTable(nrow=3, ncol=3, wrd=wrd)
WrdMergeCells(wtab, rstart=c(1,2), rend=c(2,3))
## End(Not run)
```

Description

Insert a page break in a MS-Word (R) document at the position of the cursor.

Usage

```r
WrdPageBreak(wrd = DescToolsOptions("lastWord"))
```

Arguments

- `wrd` the pointer to a word instance. Can be a new one, created by `GetNewWrd()` or an existing one, created by `GetCurrWrd()`. Default is the last created pointer stored in `DescToolsOptions("lastWord")`.

Author(s)

Andri Signorell <andri@signorell.net>

WrdFont, WrdPlot, GetNewWrd, GetCurrWrd

Examples

```r
## Not run: # Windows-specific example
wrd <- GetNewWrd()
WrdText("This is text on page 1.

")
WrdPageBreak()
WrdText("This is text on another page.\n\n")

## End(Not run)
```

WrdParagraphFormat

### Get or Set the Paragraph Format in Word

Get or Set the Paragraph Format in Word

Description

WrdParagraphFormat can be used to get and set the font in Word for the text to be inserted.

Usage

```
WrdParagraphFormat(wrd = DescToolsOptions("lastWord"))
WrdParagraphFormat(wrd) <- value
```

Arguments

- **value**
  - a list defining the paragraph format. This can contain any combination of:
    - `LeftIndent`
    - `RightIndent`
    - `SpaceBefore`
    - `SpaceBeforeAuto`
    - `SpaceAfter`
    - `SpaceAfterAuto`
    - `LineSpacingRule`
    - `Alignment`
    - `WidowControl`
    - `KeepWithNext`
    - `KeepTogether`
    - `PageBreakBefore`
    - `NoLineNumber`
    - `Hyphenation`
    - `FirstLineIndent`
    - `OutlineLevel`
    - `CharacterUnitLeftIndent`
    - `CharacterUnitRightIndent`
    - `CharacterUnitFirstLineIndent`
    - `LineUnitBefore`
    - `LineUnitAfter`
    - `MirrorIndents`
  - The possible values of the arguments are found in the Word constants with the respective name.
  - The alignment for example can be set to `wdAlignParagraphLeft`, `wdAlignParagraphRight`, `wdAlignParagraphCenter` and so on.
  - Left alignment with indentation would be set as:
    ```r
    list(Alignment=wdConst$wdAlignParagraphLeft, LeftIndent=42.55).
    ```
- **wrd**
  - the pointer to a word instance. Can be a new one, created by `GetNewWrd()` or an existing one, created by `GetCurrWrd()`. Default is the last created pointer stored in `DescToolsOptions("lastWord")`.

Value

- an object with the class `paragraph`, basically a list with the attributes of the paragraph in the current cursor position:
  - `LeftIndent` left indentation in (in points) for the specified paragraphs.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RightIndent</td>
<td>right indent (in points) for the specified paragraphs.</td>
</tr>
<tr>
<td>SpaceBefore</td>
<td>spacing (in points) before the specified paragraphs.</td>

WrdPlot

Insert Active Plot to Word

Description

This function inserts the plot on the active plot device to Word. The image is transferred by saving
the picture to a file in R and inserting the file in Word. The format of the plot can be selected, as
well as crop options and the size factor for inserting.

Usage

```r
WrdPlot(type = "png", append.cr = TRUE, crop = c(0, 0, 0, 0), main = NULL,
        picscale = 100, height = NA, width = NA, res = 300,
        dfact = 1.6, wrd = DescToolsOptions("lastWord"))
```

Arguments

- `type`: the format for the picture file, default is "png".
- `append.cr`: should a carriage return be appended? Default is TRUE.
- `crop`: crop options for the picture, defined by a 4-elements-vector. The first element is
  the bottom side, the second the left and so on.
- `main`: a caption for the plot. This will be inserted by InserCaption in Word. Default is
  NULL, which will insert nothing.
- `picscale`: scale factor of the picture in percent, default ist 100.
- `height`: height in cm, this overrides the picscale if both are given.
width width in cm, this overrides the picscale if both are given.
res resolution for the png file, defaults to 300.
dfact the size factor for the graphic.
wrd the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions("lastWord").

Value
Returns a pointer to the inserted picture.

WrdSaveAs

Open and Save Word Documents

Description
Open and save MS-Word documents.

Usage
WrdOpenFile(fn, wrd = DescToolsOptions("lastWord"))
WrdSaveAs(fn, fileformat = "docx", wrd = DescToolsOptions("lastWord"))

Arguments
fn filename and -path for the document.
fileformat file format, one out of "doc", "htm", "pdf".
wrd the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions("lastWord").

Value
nothing returned

WrdStyle

Get or Set the Style in Word

Description

WrdStyle can be used to get and set the style in Word for the text to be inserted. WrdStyle returns the style at the current cursor position.

Usage

WrdStyle(wrd = DescToolsOptions("lastWord"))
WrdStyle(wrd) <- value

Arguments

value the name of the style to be used to the output. This should be defined an existing name.

wrd the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions("lastWord").

Value

character, name of the style

Author(s)

Andri Signorell <andri@signorell.net>

See Also

ToWrd, WrdPlot, GetNewWrd, GetCurrWrd

Examples

## Not run: # Windows-specific example

wrd <- GetNewWrd()
# the current style
WrdStyle(wrd)

## End(Not run)
Description

Create a table with a specified number of rows and columns in a Word document at the current position of the cursor.

Usage

\[
\text{WrdTable}(\text{nrow} = 1, \text{ncol} = 1, \text{heights} = \text{NULL}, \text{widths} = \text{NULL}, \text{main} = \text{NULL}, \\
\text{wrd} = \text{DescToolsOptions("lastWord")})
\]

Arguments

- **nrow**: number of rows.
- **ncol**: number of columns.
- **heights**: a vector of the row heights (in cm). If set to NULL (which is the default) the Word defaults will be used. The values will be recycled, if necessary.
- **widths**: a vector of the column widths (in cm). If set to NULL (which is the default) the Word defaults will be used. The values will be recycled, if necessary.
- **main**: a caption for the plot. This will be inserted by InserCaption in Word. Default is NULL, which will insert nothing.
- **wrd**: the pointer to a word instance. Can be a new one, created by GetNewWrd() or an existing one, created by GetCurrWrd(). Default is the last created pointer stored in DescToolsOptions("lastWord").

Value

A pointer to the inserted table.

wrd <- GetNewWrd()
WrdTable(nrow=3, ncol=3, wrd=wrd)

## End(Not run)
```
Description

Drawing borders in a Word table is quite tedious. This function allows to select any range and draw border lines around it.

Usage

WrdTableBorders(wtab, from = NULL, to = NULL, border = NULL, lty = wdConst$wdLineStyleSingle, col = wdConst$wdColorBlack, lwd = wdConst$wdLineWidth050pt)

Arguments

- `wtab`: a pointer to a Word table as returned by `WrdTable` or `TOne`.
- `from`: integer, a vector with two elements specifying the left upper bound of the cell-range.
- `to`: integer, a vector with two elements specifying the right bottom of the cell-range.
- `border`: a Word constant (wdConst$wdBorder...) defining the side of the border.
- `lty`: a Word constant (wdConst$wdLineStyle...) defining the line type.
- `col`: a Word constant (wdConst$wdColor...) defining the color of the border. See examples for converting R colors to Word colors.
- `lwd`: a Word constant (wdConst$wdLineWidth...pt) defining the line width.

Value

nothing

tab <- table(op=d.pizza$operator, area=d.pizza$area)

# send it to Word
wrd <- GetNewWrd()
```
XLDateToPOSIXct

Convert Excel Dates to POSIXct

Description

As I repeatedly forgot how to convert Excel dates to POSIX here's the specific function.

Usage

XLDateToPOSIXct(x, tz = "GMT", xl1904 = FALSE)

Arguments

x  the integer vector to be converted.

 tz  a time zone specification to be used for the conversion, if one is required. See as.POSIXct.

xl1904  logical, defining if the unspeakable 1904-system should be used. Default is FALSE.

Details

XLGetRange will return dates as integer values, because XL stores them as integers. An Excel date can be converted with the (unusual) origin of as.Date(myDate,origin="1899-12-30"), which is implemented here.

Microsoft Excel supports two different date systems, the 1900 date system and the 1904 date system. In the 1900 date system, the first day that is supported is January 1, 1900. A date is converted...
into a serial number that represents the number of elapsed days since January 1, 1900. In the 1904 date system, the first day that is supported is January 1, 1904. By default, Microsoft Excel for the Macintosh uses the 1904 date system, Excel for Windows the 1900 system. See also: https://support.microsoft.com/en-us/214330.

Value

return an object of the class POSIXct. Date-times known to be invalid will be returned as NA.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

as.POSIXct

Examples

XLDateToPOSIXct(41025)
XLDateToPOSIXct(c(41025.23, 41035.52))

Description

The package RDCOMClient is used to open an Excel workbook and return the content (value) of one (or several) given range(s) in a specified sheet. This is helpful, whenever pathologically scattered data on an Excel sheet, which can’t simply be saved as CSV-file, has to be imported in R.

XLGetWorkbook() does the same for all the sheets in an Excel workbook.

Usage

XLGetRange(file = NULL, sheet = NULL, range = NULL, as.data.frame = TRUE, header = FALSE, stringsAsFactors = FALSE, echo = FALSE, na.strings = NULL, skip = 0)

XLGetWorkbook(file, compactareas = TRUE)

XLCurrReg(cell)
XLNamedReg(x)
**Arguments**

- **file**: the fully specified path and filename of the workbook. If it is left as `NULL`, the function will look for a running Excel-Application and use its current sheet. The parameter sheet will be ignored in this case.
- **sheet**: the name of the sheet containing the range(s) of interest.
- **range**: a scalar or a vector with the address(es) of the range(s) to be returned (characters). Use "A1"-address mode to specify the ranges, for example "A1:F10". If set to `NULL` (which is the default), the function will look for a selection that contains more than one cell. If found, the function will use this selection. If there is no selection then the current region of the selected cell will be used. Use `XLCurrReg()` if the current region of a cell, which is currently not selected, should be used. Range names can be provided with `XLNamedReg("name")`.
- **as.data.frame**: logical. Determines if the cellranges should be coerced into data.frames. Defaults to TRUE, as this is probably the common use of this function.
- **header**: a logical value indicating whether the range contains the names of the variables as its first line. Default is FALSE. header is ignored if as.data.frame has been set to FALSE.
- **stringsAsFactors**: logical. Should character columns be coerced to factors? The default is FALSE, which will return character vectors.
- **echo**: logical. If set to TRUE, the function will print the full command used, such that it can be copied into the R-script for future use.
- **na.strings**: a character vector of strings which are to be interpreted as NA values. Blank fields are always considered to be missing values. Default is NULL, meaning none.
- **compactareas**: logical, defining if areas should be returned by `XLGetWorkbook` as list or as matrix (latter is default).
- **cell**: range of the left uppe cell, when current region should be used.
- **x**: then name or the index of the XL-name to be used.
- **skip**: the number of lines of the data file to skip before beginning to read data.

**Details**

The result consists of a list of lists, if as.data.frame is set to FALSE. Be then prepared to encounter NULL values. Those will prevent from easily being able to coerce the square data structure to a data.frame.

The following code will replace the NULL values by NA and coerce the data to a data.frame.

```r
# get the range D1:J69 from an excel file
xlrng <- XLGetRange(file="myfile.xlsx", sheet="Tabelle1",
                    range="D1:J69", as.data.frame=FALSE)

# replace NULL values by NA
xlrng[unlist(lapply(xlrng, is.null))] <- NA
```
# coerce the square data structure to a data.frame

d.lka <- data.frame(lapply(data.frame(xlrng), unlist))

This of course can be avoided by setting `as.data.frame = TRUE`.

The function will return dates as integers, because MS-Excel stores them internally as integers. Such a date can subsequently be converted with the (unusual) origin of `as.Date(myDate, origin="1899-12-30")`. See also `XLDatesToPOSIXct`, which does the job. The conversion can directly be performed by `XLGetRange()` if `datecols` is used and contains the date columns in the sheet data.

**Value**

If `as.data.frame` is set to `TRUE`, a single data.frame or a list of data.frames will be returned. If set to `FALSE` a list of the cell values in the specified Excel range, resp. a list of lists will be returned.

`XLGetWorkbook()` returns a list of lists of the values in the given workbook.

**Examples**

```r
## Not run:  # Windows-specific example

XLGetRange(file="C:\My Documents\data.xls",
sheet="Sheet1",
range=c("A2:B5","M6:X23","C4:D40"))

# if the current region has to be read (incl. a header), place the cursor in the interesting region
# and run:

d.set <- XLGetRange(header=TRUE)

# Get XL nameslist

nm <- xl$ActiveWorkbook()$names()

lst <- list()
for(i in 1:nm$count())
    lst[[i]] <- c(name=nm[[i]]$name(),
                 address=nm[[i]]$refersToRange()$Address())

# the defined names

as.data.frame(do.call(rbind, lst), stringsAsFactors = FALSE)

## End(Not run)
```
XLSaveAs

Save Excel File

Description

Save the current workbook under the given name and format.

Usage

XLSaveAs(fn, file_format = xlConst$XlFileFormat$xlWorkbookNormal, xl = DescToolsOptions("lastXL"))

Arguments

fn  the filename
file_format  the file format using the xl constant.
xl  the pointer to a MS-Excel instance. An new instance can be created with GetNewXL(), returning the appropriate handle. A handle to an already running instance is returned by GetCurrXL(). Default is the last created pointer stored in DescToolsOptions("lastXL").

Value

returns TRUE if the save operation has been successful

Author(s)

Andri Signorell <andri@signorell.net>

XLView

Examples

## Not run: # Windows-specific example
XLView(d.diamonds)
XLSaveAs("Diamonds")
xl$quit()

## End(Not run)
**XLView**

*Use MS-Excel as Viewer for a Data.Frame*

**Description**

XLView can be used to view and edit a data.frame directly in MS-Excel, resp. to create a new data.frame in MS-Excel.

**Usage**

```r
XLView(x, col.names = TRUE, row.names = FALSE, na = "", preserveStrings = FALSE)
```

```r
ToXL(x, at, ..., xl=DescToolsOptions("lastXL"))
```

```r
## S3 method for class 'data.frame'
ToXL(x, at, ..., xl=DescToolsOptions("lastXL"))
```

```r
## S3 method for class 'matrix'
ToXL(x, at, ..., xl=DescToolsOptions("lastXL"))
```

```r
## Default S3 method:
ToXL(x, at, byrow = FALSE, ..., xl=DescToolsOptions("lastXL"))
```

XLKill()

**Arguments**

- **x**
  is a data.frame to be transferred to MS-Excel. If data is missing a new file will be created.

- **row.names**
  either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written.

- **col.names**
  either a logical value indicating whether the column names of x are to be written along with x, or a character vector of column names to be written. See the section on 'CSV files' write.table for the meaning of col.names = NA.

- **na**
  the string to use for missing values in the data.

- **preserveStrings**
  logical, will preserve strings from being converted to numerics when imported in MS-Excel. See details. Default is FALSE.

- **at**
  can be a range adress as character (e.g. "A1"), a vector of 2 integers (e.g c(1,1)) or a cell object as it is returned by xl$Cells(1,1), denoming the left upper cell, where the data.frame will be placed in the MS-Excel sheet.

- **byrow**
  logical, defines if the vector should be inserted by row or by column (default).

- **xl**
  the pointer to a MS-Excel instance. An new instance can be created with GetNewXL(), returning the appropriate handle. A handle to an already running instance is returned by GetCurrXL(). Default is the last created pointer stored in DescToolsOptions("lastXL").

- **...**
  further arguments are not used.
The data.frame will be exported in CSV format and then imported in MS-Excel. When importing data, MS-Excel will potentially change characters to numeric values. If this seems undesirable (maybe we’re loosing leading zeros) then you should enclose the text in quotes and preset a =. x <- gettextf(‘"%s"’, x) would do the trick.

Take care: Changes to the data made in MS-Excel will NOT automatically be updated in the original data.frame. The user will have to read the csv-file into R again. See examples how to get this done.

ToXL() is used to export data frames or vectors directly to MS-Excel, without export the data to a csv-file and import it on the XL side. So it it possible to export several data.frames into one Workbook and edit the tables after ones needs.

XLKill will kill a running XL instance (which might be invisible). Background is the fact, that the simple XL$quit() command would not terminate a running XL task, but only set it invisible (observe the TaskManager). This ghost version may sometimes confuse XLView and hinder to create a new instance. In such cases you have to do the garbage collection...

the name/path of the temporary file edited in MS-Excel.

The function works only in Windows and requires RDCOMClient to be installed (see: Additional_repositories in DESCRIPTION of the package).

Andri Signorell <andri@signorell.net>, ToXL() is based on code of Duncan Temple Lang <duncan@r-project.org>

GetNewXL, XLGetRange, XLGetWorkbook

## Not run:
# Windows-specific example
XLView(d.diamonds)

# edit an existing data.frame in MS-Excel, make changes and save there, return the filename
fn <- XLView(d.diamonds)
# read the changed file and store in new data.frame
d.frm <- read.table(fn, header=TRUE, quote="", sep=";")

# Create a new file, edit it in MS-Excel...
fn <- XLView()}
Yuen T-Test

Description

Performs one and two sample Yuen t-tests for trimmed means on vectors of data.
Usage

YuenTTest(x, ...)

## Default S3 method:
YuenTTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
         mu = 0, paired = FALSE, conf.level = 0.95, trim = 0.2, ...
)

## S3 method for class 'formula'
YuenTTest(formula, data, subset, na.action, ...)

Arguments

x numeric vector of data values. Non-finite (e.g. infinite or missing) values will
be omitted.

y an optional numeric vector of data values: as with x non-finite values will be
omitted.

alternative is a character string, one of "greater", "less", or "two.sided", or the initial
letter of each, indicating the specification of the alternative hypothesis. For one-
sample tests, alternative refers to the true median of the parent population in
relation to the hypothesized value of the mean.

paired a logical indicating whether you want a paired z-test.

mu a number specifying the hypothesized mean of the population.

cnf.level confidence level for the interval computation.

trim the fraction (0 to 0.5) of observations to be trimmed from each end of x before
the mean is computed. Values of trim outside that range are taken as the nearest
endpoint.

formula a formula of the form lhs ~ rhs where lhs gives the data values and rhs the
corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing
the variables in the formula formula. By default the variables are taken from
environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. De-
faults togetOption("na.action").

... further arguments to be passed to or from methods.

Value

An object of class htest containing the following components:

statistic the value of the t-statistic.

parameter the degrees of freedom for the t-statistic and the trim percentage used.

p.value the p-value for the test.
conf.int  a confidence interval for the trimmed mean appropriate to the specified alternative hypothesis.
estimate the estimated trimmed mean or difference in trimmed means depending on whether it was a one-sample test or a two-sample test.
null.value the specified hypothesized value of the trimmed mean or trimmed mean difference depending on whether it was a one-sample test or a two-sample test.
alternative a character string describing the alternative hypothesis.
method a character string indicating what type of test was performed.
data.name a character string giving the name(s) of the data.

Author(s)
Andri Signorell <andri@signorell.net>, based on R-Core code of t.test

with(d.oxen, YuenTTest(int, ext, paired=FALSE))
ZeroIfNA

Replace NAs by 0

Description

Replace NAs in a numeric vector x with 0. This function has the same logic as the zeroifnull function in SQL. NAfZero() does replace zeros with NA. BlankIfNA() and NAfBlank() do the same, but for character vectors.

Usage

ZeroIfNA(x)
NAfZero(x)

BlankIfNA(x, blank="")
NAfBlank(x)

Impute(x, FUN = function(x) median(x, na.rm = TRUE))

Arguments

x the vector x, whose NAs should be overwritten with 0s.
blank a character to be used for "blank". Default is an empty string ("").
FUN the name of a function to be used as imputation. Can as well be a self defined function or a constant value. Default is median.

Value

the edited vector x

# [1] 8 8 9 8 3
Calculate the Zodiac of a Date

Description

Calculate the sign of zodiac of a date.

Usage

Zodiac(x, lang = c("engl", "deu"), stringsAsFactors = TRUE)

Arguments

x
the date to be transformed.
lang
the language of the zodiac names, can be english (default) or german ("deu").
stringsAsFactors
   logical. If set to TRUE (default) the result will consist of a factor with zodiac signs as levels.

Details

The really relevant things can sometimes hardly be found. You just discovered such a function... ;-

Value

character vector or factor with the zodiac.

Author(s)

Andri Signorell <andri@signorell.net>, based on code from Markus Naepflin

d <- sample(seq(as.Date("2015-01-01"), as.Date("2015-12-31"), 1), 120)
z <- Zodiac(d)
Desc(z)
ZTest

Z Test for Known Population Standard Deviation

Description

Compute the test of hypothesis and compute confidence interval on the mean of a population when the standard deviation of the population is known.

Usage

ZTest(x, ...)

## Default S3 method:
ZTest(x, y = NULL, alternative = c("two.sided", "less", "greater"),
       paired = FALSE, mu = 0, sd_pop, conf.level = 0.95, ...)

## S3 method for class 'formula'
ZTest(formula, data, subset, na.action, ...)

Arguments

x numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.

y an optional numeric vector of data values: as with x non-finite values will be omitted.

mu a number specifying the hypothesized mean of the population.

sd_pop a number specifying the known standard deviation of the population.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. For one-sample tests, alternative refers to the true mean of the parent population in relation to the hypothesized value of the mean.

paired a logical indicating whether you want a paired z-test.

conf.level confidence level for the interval computation.

formula a formula of the form lhs ~ rhs where lhs gives the data values and rhs a factor with two levels giving the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

... further arguments to be passed to or from methods.
Details

Most introductory statistical texts introduce inference by using the z-test and z-based confidence intervals based on knowing the population standard deviation. However statistical packages often do not include functions to do z-tests since the t-test is usually more appropriate for real world situations. This function is meant to be used during that short period of learning when the student is learning about inference using z-procedures, but has not learned the t-based procedures yet. Once the student has learned about the t-distribution the t.test() function should be used instead of this one (but the syntax is very similar, so this function should be an appropriate introductory step to learning t.test()).

The formula interface is only applicable for the 2-sample tests.

Value

A list with class "htest" containing the following components:

- statistic the value of the z-statistic.
- p.value the p-value for the test
- conf.int a confidence interval for the mean appropriate to the specified alternative hypothesis.
- estimate the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.
- null.value the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
- alternative a character string describing the alternative hypothesis.
- method a character string indicating what type of test was performed.
- data.name a character string giving the name(s) of the data.

Author(s)

Andri Signorell <andri@signorell.net>, based on R-Core code of t.test, documentation partly from Greg Snow <greg.snow@imail.org>

### Like Operator

**Description**

The like operator is a simple wrapper for `grep(...,value=TRUE)`, whose complexity is hard to crack for R-newbies.

**Usage**

- `x %like% pattern`
- `x %like any% pattern`

**Arguments**

- `x`: A vector, typically of character or factor type
- `pattern`: Simple character string to be matched in the given character vector.

**Details**

Follows the logic of simple SQL or basic commands.

**Value**

A vector (numeric, character, factor), matching the mode of `x`

**Author(s)**

Andri Signorell <andri@signorell.net>

**See Also**

`match`, `pmatch`, `grep`, `%[]%`, `%overlaps%`
%nin%

Examples

# find names ending on "or"
names(d.pizza) %like% "%or"

# find names starting with "d"
names(d.pizza) %like% "d%"

# ... containing er?
names(d.pizza) %like% "%er%"

# and combined, search for a name containing "un", ending on "or"
# or beginning with "F"
levels(d.pizza$driver) %like any% c("%un%", "%or", "F%")

# the positions on the vector
match(names(d.pizza) %like% "%er%", names(d.pizza))

%nin%  Find Matching (or Non-Matching) Elements

Description

%nin% is a binary operator, which returns a logical vector indicating if there is a match or not for its left operand. A true vector element indicates no match in left operand, false indicates a match.

Usage

x %nin% table

Arguments

x a vector (numeric, character, factor)
table a vector (numeric, character, factor), matching the mode of x

Value

vector of logical values with length equal to length of x.

Author(s)

Frank E Harrell Jr <f.harrell@vanderbilt.edu>

match, %in%

Examples

c('a','b','c') %nin% c('a','b')
%overlaps% \( \textit{Determines If And How Extensively Two Date Ranges \textit{Overlap}} \)

\textbf{Description}

%overlaps% determines if two date ranges overlap at all and returns a logical value. Interval returns the number of days of the overlapping part of the two date periods. Inspired by the eponymous SQL-functions.

\textbf{Usage}

\begin{align*}
\text{x} \ %\text{overlaps}\% \ y \\
\text{Overlap}(x, y) \\
\text{Interval}(x, y)
\end{align*}

\textbf{Arguments}

\begin{itemize}
\item \texttt{x} \hspace{1cm} range 1, vector of 2 numeric values or matrix with 2 columns, the first defining the left point the second the right point of the range.
\item \texttt{y} \hspace{1cm} range 2, vector of 2 numeric values or matrix with 2 columns, the first defining the left point the second the right point of the range.
\end{itemize}

\textbf{Details}

%overlaps% returns TRUE or FALSE depending on if the two ranges overlap. The function Overlap returns the range of the overlapping region as numeric value. This will be 0, if the ranges do not overlap.

Interval returns the width of the empty space between 2 ranges. Again this will be 0 if the ranges overlap.

To handle overlapping ranges there are 4 cases to consider:

\begin{center}
\begin{tabular}{l}
\text{range a:} \hspace{1cm} [---------] \\
\text{range b:} \hspace{1cm} [----] \\
\text{range c:} \hspace{1cm} [------] \\
\text{range d:} \hspace{1cm} [-----] \\
\end{tabular}
\end{center}

\begin{center}
\begin{tabular}{cccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8
\end{tabular}
\end{center}

Ranges a and b overlap, the function Overlap will return the absolute value of the overlapping region (which will be 3 - 2 = 1 in this case). The result will be the same for Overlap\((a, b)\) and Overlap\((b, a)\).

Interval will have a direction. Ranges b and c do not overlap, Overlap will return 0, %overlaps% FALSE. Interval will return 2 for the case Interval\((a, b)\) and -2 for Interval\((b, a)\).

This functions can be of value, if one has to decide, whether confidence intervals overlap or not.
Value

returns a logical vector (match or not for each element of x). Interval and Overlap return a numeric vector.

# works with numerics as well
c(1, 18) %overlaps% c(10, 45)

%c%  Concatenates Two Strings Without Any Separator

Description

%c% is just a short operator implementation for paste(x, y, separator="").

Usage

x %c% y

Arguments

x  first string
y  second string, which will be pasted behind the first one.
Details

R-Core does not consider it a good idea to use + as an operator not being commutative. So we use c here.
See the discussion: https://stat.ethz.ch/pipermail/r-devel/2006-August/039013.html
and http://stackoverflow.com/questions/1319698/why-doesnt-operate-on-characters-in-r?

Still the paste syntax seems sometimes clumsy in daily life and so %c% might spare some keys.

Value

returns the concatenation as string.
