Package ‘Greg’

June 25, 2020

Version 1.3.4
Date 2020-06-24
Title Regression Helper Functions
Maintainer Max Gordon <max@gforge.se>
Description Methods for manipulating regression models and for describing these in a style adapted for medical journals. Contains functions for generating an HTML table with crude and adjusted estimates, plotting hazard ratio, plotting model estimates and confidence intervals using forest plots, extending this to comparing multiple models in a single forest plots. In addition to the descriptive methods, there are add-ons for the robust covariance matrix provided by the 'sandwich' package, a function for adding non-linearities to a model, and a wrapper around the 'Epi' package's Lexis() functions for time-splitting a dataset when modeling non-proportional hazards in Cox regressions.

Description

This R-package provides functions that primarily aimed at helping you work with regression models. While much of the data presented by the standard regression output is useful and important - there is often a need for further simplification prior to publication. The methods implemented in this package are inspired by some of the top journals such as NEJM, BMJ, and other medical journals as this is my research field.

Output functions

The package has function that automatically prints the crude unadjusted estimates of a function next to the adjusted estimates, a common practice for medical publications.

The forestplot wrappers allows for easily displaying regression estimates, often convenient for models with a large number of variables. There is also functionality that can help you comparing different models, e.g. subsets of patients or compare different regression types.

Time-splitter

When working with Cox regressions the proportional hazards can sometimes be violated. As the \texttt{tt()} approach doesn’t lend itself that well to big datasets I often rely on time-splitting the dataset and then using the start time as an interaction term. See the function \texttt{timeSplitter()} and the associated vignette("timeSplitter").

Other regression functions

In addition to these function the package has some extentions to linear regression where it extends the functionality by allowing for robust covariance matrices. by integrating the \texttt{sandwich}-package for \texttt{ols()}.
addNonlinearity

Important notice

This package has an extensive test-set for ensuring that everything behaves as expected. Despite this I strongly urge you to check that the values make sense. I commonly use the regression methods available in the 'rms'-package and in the 'stats'-package. In addition I use the `coxph()` in many of my analyses and should also be safe. Please send me a notice if you are using the package with some other regression models, especially if you have some tests verifying the functionality.

### addNonlinearity

Add a nonlinear function to the model

#### Description

This function takes a model and adds a non-linear function if the likelihood-ratio supports this (via the `anova(..., test = "chisq")` test for `stats` while for `rms` you need to use the `rcs()` spline that is automatically evaluated for non-linearity).

#### Usage

```r
addNonlinearity(
  model, 
  variable, 
  spline_fn, 
  flex_param = 2:7, 
  min_fn = AIC, 
  sig_level = 0.05, 
  verbal = FALSE, 
  workers, 
  ...
)
```

```r
## S3 method for class 'negbin'
addNonlinearity(model, ...)
```

#### Arguments

- **model**: The model that is to be evaluated and adapted for non-linearity
- **variable**: The name of the parameter that is to be tested for non-linearity. Note that the variable should be included plain (i.e. as a linear variable) form in the model.
- **spline_fn**: Either a string or a function that is to be used for testing alternative non-linearity models
- **flex_param**: A vector with values that are to be tested as the default second parameter for the non-linearity function that you want to evaluate. This defaults to 2:7, for the `ns()` it tests the degrees of freedom ranging between 2 and 7.
This is the function that we want to minimized if the variable supports the non-linearity assumption. E.g. BIC() or AIC, note that the BIC() will in the majority of cases support a lower complexity than the AIC().

The significance level for which the non-linearity is deemed as significant, defaults to 0.05.

Set this to TRUE if you want print statements with the anova test and the chosen knots.

The function tries to run everything in parallel. Under some circumstances you may want to restrict the number of parallel threads to less than the default detectCores() -1, e.g. you may run out of memory then you can provide this parameter. If you do not want to use parallel then simply set workers to FALSE. The cluster created using makeCluster() function.

Passed onto internal prNlChooseDf() function.

Examples

```r
library(Greg)
library(magrittr)
data("melanoma", package = "boot", envir = environment())

library(dplyr)
library(magrittr)
melanoma %<>%
  mutate(status = factor(status,
    levels = 1:3,
    labels = c("Died from melanoma",
      "Alive",
      "Died from other causes")),
  ulcer = factor(ulcer,
    levels = 0:1,
    labels = c("Absent", "Present")),
  time = time/365.25, # All variables should be in the same time unit
  sex = factor(sex,
    levels = 0:1,
    labels = c("Female", "Male")))

library(survival)
model <- coxph(Surv(time, status == "Died from melanoma") ~ sex + age,
  data = melanoma)

nl_model <- addNonlinearity(model, "age",
  spline_fn = "pspline",
  verbal = TRUE,
  workers = FALSE)

# Note that there is no support for nonlinearity in this case
```
caDescribeOpts

A function for gathering all the description options

Description

Since there are so many different description options for the `printCrudeAndAdjustedModel()` function they have been gathered into a list. This function is simply a helper in order to generate a valid list.

Usage

```r
caDescribeOpts(
  show_tot_perc = FALSE,
  numb_first = TRUE,
  continuous_fn = describeMean,
  prop_fn = describeFactors,
  factor_fn = describeFactors,
  digits = 1,
  colnames = c("Total", "Event")
)
```

Arguments

- `show_tot_perc`: Show percentages for the total column
- `numb_first`: Whether to show the number before the percentages
- `continuous_fn`: Stat function used for the descriptive statistics, defaults to `describeMean()`
- `prop_fn`: Stat function used for the descriptive statistics, defaults to `describeFactors()` since there has to be a reference in the current setup.
- `factor_fn`: Stat function used for the descriptive statistics, defaults to `describeFactors()`
- `digits`: Number of digits to use in the descriptive columns. Defaults to the general digits if not specified.
- `colnames`: The names of the two descriptive columns. By default Total and Event.

Value

- `list`: Returns a list with all the options
A confint function for the ols

Description
This function checks that there is a df.residual before running the qt(). If not found it then defaults to the qnorm() function. Otherwise it is a copy of the confint() function.

Usage
## S3 method for class 'ols'
confint(object, parm, level = 0.95, ...)

Arguments

- **object**
  - a fitted ols-model object.

- **parm**
  - a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.

- **level**
  - the confidence level required.

- **...**
  - additional argument(s) for methods.

Value
A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in

Examples

```r
# Generate some data
n <- 500
x1 <- runif(n) * 2
x2 <- runif(n)
y <- x1^3 + x2 + rnorm(n)

library(rms)
library(sandwich)
dd <- datadist(x1, x2, y)
org.op <- options(datadist = "dd")

# Main function
f <- ols(y ~ rcs(x1, 3) + x2)

# Check the bread
bread(f)
# Check the HC-matrix
vcovHC(f, type = "HC4m")
# Adjust the model so that it uses the HC4m variance
```
confint_robust

f_rob <- robcov_alt(f, type = "HC4m")
# Get the new HC4m-matrix
# - this function just returns the f_rob$var matrix
vcov(f_rob)
# Now check the confidence interval for the function
confint(f_rob)
options(org.op)

---

confint_robust  

The confint function adapted for vcovHC

Description

The confint.lm uses the t-distribution as the default confidence interval estimator. When there is reason to believe that the normal distribution is violated an alternative approach using the vcovHC() may be more suitable.

Usage

confint_robust(
    object,
    parm,
    level = 0.95,
    HC_type = "HC3",
    t_distribution = FALSE,
    ...
)

Arguments

object The regression model object, either an ols or lm object
parm a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
level the confidence level required.
HC_type See options for vcovHC()
t_distribution A boolean for if the t-distribution should be used or not. Defaults to FALSE. According to Cribari-Nieto and Lima’s study from 2009 this should not be the case.
... Additional parameters that are passed on to vcovHC()

Value

matrix A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in
References

Examples

```r
n <- 50
x <- runif(n)
y <- x + rnorm(n)

fit <- lm(y~x)
library("sandwich")
confint_robust(fit, HC_type = "HC4m")
```

Description

Creates a composite from different regression objects into one forestplot where you can choose the variables of interest to get an overview and easier comparison.

Usage

```r
forestplotCombineRegrObj(
  regr.obj,  # A list with all the fits that have variables that are to be identified through the regular expression
  variablesOfInterest.regexp,
  reference.names,
  rowname.fn,
  estimate.txt,
  exp = xlog,
  add_first_as_ref = FALSE,
  ref_txt = "ref.",
  ref_labels = c(),
  digits = 1,
  is.summary,
  xlab,
  zero,
  xlog,
  ...
)
```

Arguments

- `regr.obj`: A list with all the fits that have variables that are to be identified through the regular expression
variablesOfInterest.regexp
A regular expression identifying the variables that are of interest of comparing. For instance it can be "(score|index|measure)" that finds scores in different models that should be compared.

reference.names
Additional reference names to be added to each model

rownames.fn
A function that takes a row name and sees if it needs beautifying. The function has only one parameter the coefficients name and should return a string or expression.

estimate.txt
The text of the estimate, usually HR for hazard ratio, OR for odds ratio

exp
Report in exponential form. Default true since the function was built for use with survival models.

add_first_as_ref
If you want that the first variable should be reference for that group of variables. The ref is a variable with the estimate 1 or 0 depending if exp() and the confidence interval 0.

ref_txt
Text instead of estimate number

ref_labels
If add_first_as_ref is TRUE then this vector is used for the model fits.

digits
Number of digits to use for the estimate output

is.summary
A vector indicating by TRUE/FALSE if the value is a summary value which means that it will have a different font-style

xlab
x-axis label

zero
Indicates what is zero effect. For survival/logistic fits the zero is 1 while in most other cases it's 0.

xlog
If TRUE, x-axis tick marks are to follow a logarithmic scale, e.g. for logistic regression (OR), survival estimates (HR), poisson regression etc. **Note:** This is an intentional break with the original forestplot function as I've found that exponentiated ticks/clips/zero effect are more difficult to for non-statisticians and there are sometimes issues with rounding the tick marks properly.

... Passed to forestplot()

See Also
Other forestplot wrappers: forestplotRegrObj()

Examples

```r
org.par <- par("ask" = TRUE)

# simulated data to test
set.seed(10)
ftime <- rexp(200)
fstatus <- sample(0:1, 200, replace = TRUE)
cov <- data.frame(
  x1 = runif(200),
  x2 = runif(200),
```
x3 = runif(200)
)

library(rms)
ddist <- datadist(cov)
options(datadist = "ddist")

fit1 <- cph(Surv(ftime, fstatus) ~ x1 + x2, data = cov)
fit2 <- cph(Surv(ftime, fstatus) ~ x1 + x3, data = cov)

forestplotCombineRegrObj(
  regr.obj = list(fit1, fit2),
  variablesOfInterest.regexp = "(x2|x3)",
  reference.names = c("First model", "Second model"),
  new_page = TRUE
)

modifyNameFunction <- function(x) {
  if (x == "x1") {
    return("Covariate A")
  }
  if (x == "x2") {
    return(expression(paste("My \( \beta \)")))
  }
  return(x)
}

forestplotCombineRegrObj(
  regr.obj = list(fit1, fit2),
  variablesOfInterest.regexp = "(x2|x3)",
  reference.names = c("First model", "Second model"),
  rowname.fn = modifyNameFunction,
  new_page = TRUE
)

par(org.par)

---

**Forest plot for multiple models**

**Description**

Plot different model fits with similar variables in order to compare the model’s estimates and confidence intervals. Each model is represented by a separate line on top of each other and are therefore ideal for comparing different models. This extra appealing when you have lots of variables included in the models.
forestplotRegrObj

Usage

forestplotRegrObj(
  regr.obj,
  skip.variables,
  add.empty_row,
  order.regexps,
  order.addrows,
  box.default.size,
  rowname.fn,
  xlab,
  xlog,
  exp,
  estimate.txt = xlab,
  zero,
  get_box_size = fpBoxSize,
  ...
)

fpBoxSize(p_values, variable_count, box.default.size, significant = 0.05)

Arguments

regr.obj  A regression model object. It should be of coxph, crr or glm class. Warning: The glm is not fully tested.

skip.variables Which variables to use. The variables should be the names of the fit output and not the true output names if you’re using the rowname_translate_function.

add.empty_row Add empty rows. This can either be a vector or a list. When you have a vector the number indicates the row number where the empty row should be added, the format is: c(3, 5). If you give a list you have the option of specifying the name of the row, the format is: list(list(3,"my rowname"),list(5,"my other rowname")). The rows will be added at the 3rd row and 5th row from the original position. Ie you don’t have take into account that the 5:th row will be at the 6:th position after adding the 3rd row.

order.regexps A regexp vector that searches for matches along the original rownames and reorders according to those.

order.addrows If there are ordered groups then often you want empty rows that separate the different groups. Set this to true if you want to add these empty rows between groups.

box.default.size The default box size

rowname.fn A function that takes a row name and sees if it needs beautifying. The function has only one parameter the coefficients name and should return a string or expression.

xlab x-axis label

xlog If TRUE, x-axis tick marks are to follow a logarithmic scale, e.g. for logistic regression (OR), survival estimates (HR), poisson regression etc. Note: This is
an intentional break with the original `forestplot` function as I've found that exponentiated ticks/clips/zero effect are more difficult to for non-statisticians and there are sometimes issues with rounding the tick marks properly.

`exp` Report in exponential form. Default true since the function was built for use with survival models.

`estimate.txt` The text of the estimate, usually HR for hazard ratio, OR for odds ratio

`zero` Indicates what is zero effect. For survival/logistic fits the zero is 1 while in most other cases it's 0.

`get_box_size` A function for extracting the box sizes

`...` Passed to `forestplot()`

`p_values` The p-values that will work as the foundation for the box size

`variable_count` The number of variables

`significant` Level of significance .05

See Also

Other forestplot wrappers: `forestplotCombineRegrObj()`

Examples

```r
org.par <- par("ask" = TRUE)

# simulated data to test
set.seed(10)
ftime <- rexp(200)
fstatus <- sample(0:2, 200, replace = TRUE)
cov <- data.frame(
  x1 = runif(200),
  x2 = runif(200),
  x3 = runif(200)
)

library(rms)
dd <- datadist(cov)
options(datadist = "dd")

fit1 <- cph(Surv(ftime, fstatus == 1) ~ x1 + x2 + x3, data = cov)
fit2 <- cph(Surv(ftime, fstatus == 2) ~ x1 + x2 + x3, data = cov)

forestplotRegrObj(regr.obj = fit1, new_page = TRUE)
library(forestplot)
forestplotRegrObj(
  regr.obj = list(fit1, fit2),
  legend = c("Status = 1", "Status = 2"),
  legend_args = fpLegend(title = "Type of regression"),
  new_page = TRUE
)
```
modifyNameFunction <- function(x) {
  if (x == "x1") {
    return("Covariate A")
  }

  if (x == "x2") {
    return(expression(paste("My ", beta[2])))
  }

  return(x)
}

forestplotRegrObj(
  regr.obj = list(fit1, fit2),
  col = fpColors(box = c("darkblue", "darkred")),
  variablesOfInterest.regexp = "(x2|x3)",
  legend = c("First model", "Second model"),
  legend_args = fpLegend(title = "Models"),
  rowname.fn = modifyNameFunction, new_page = TRUE
)

par(org.par)

---

isFitCoxPH

*Functions for checking regression type*

**Description**

The *isFitCoxPH* function checks if the object inherits either "coxph" or "crr" class indicating that it is a survival function.

**Usage**

isFitCoxPH(fit)

isFitLogit(fit)

**Arguments**

- **fit**: Regression object

**Value**

- boolean: Returns TRUE if the object is of that type otherwise it returns FALSE.
# Examples

```r
# simulated data to use
set.seed(10)
ds <- data.frame(
  ftime = rexp(200),
  fstatus = sample(0:1, 200, replace = TRUE),
  x1 = runif(200),
  x2 = runif(200),
  x3 = runif(200)
)

library(survival)
library(rms)

dd <- datadist(ds)
options(datadist = "dd")

s <- Surv(ds$ftime, ds$fstatus == 1)
fit <- cph(s ~ x1 + x2 + x3, data = ds)
if (isFitCoxPH(fit)) {
  print("Correct, the cph is of cox PH hazard type")
}

fit <- coxph(s ~ x1 + x2 + x3, data = ds)
if (isFitCoxPH(fit)) {
  print("Correct, the coxph is of cox PH hazard type")
}

library(cmprsk)
set.seed(10)
ftime <- rexp(200)
status <- sample(0:2, 200, replace = TRUE)
cov <- matrix(runif(600), nrow = 200)
dimnames(cov)[[2]] <- c("x1", "x2", "x3")
fit <- crr(ftime, fstatus, cov)
if (isFitCoxPH(fit)) {
  print(paste(
    "Correct, the competing risk regression is",
    "considered a type of cox regression",
    "since it has a Hazard Ratio"
  ))
}

# ** Borrowed code from the lrm example **

# Fit a logistic model containing predictors age, blood.pressure, sex
# and cholesterol, with age fitted with a smooth 5-knot restricted cubic
# spline function and a different shape of the age relationship for males
# and females.

n <- 10000 # define sample size
```
set.seed(17) # so can reproduce the results
age <- rnorm(n, 50, 10)
blood.pressure <- rnorm(n, 120, 15)
cholesterol <- rnorm(n, 200, 25)
sex <- factor(sample(c("female", "male"), n, TRUE))
label(age) <- "Age" # label is in Hmisc
label(cholesterol) <- "Total Cholesterol"
label(blood.pressure) <- "Systolic Blood Pressure"
label(sex) <- "Sex"
units(cholesterol) <- "mg/dl" # uses units.default in Hmisc
units(blood.pressure) <- "mmHg"

# To use prop. odds model, avoid using a huge number of intercepts by
# grouping cholesterol into 40-tiles
L <- .4 * (sex == "male") + .045 * (age - 50) +
( log(cholesterol - 10) - 5.2 ) * (-2 * (sex == "female") + 2 * (sex == "male"))

# Simulate binary y to have Prob(y = 1) = 1/[1+exp(-L)]
y <- ifelse(runif(n) < plogis(L), 1, 0)
cholesterol[1:3] <- NA # 3 missings, at random

ddist <- datadist(age, blood.pressure, cholesterol, sex)
options(datadist = "ddist")

fit_lrm <- lrm(y ~ blood.pressure + sex * (age + rcs(cholesterol, 4)),
x = TRUE, y = TRUE)
if (isFitLogit(fit_lrm) == TRUE) {
  print("Correct, the lrm is a logistic regression")
}

fit_lm <- lm(blood.pressure ~ sex)
if (isFitLogit(fit_lm) == FALSE) {
  print("Correct, the lm is not a logistic regression")
}

fit_glm_logit <- glm(y ~ blood.pressure + sex * (age + rcs(cholesterol, 4)),
  family = binomial())
if (isFitLogit(fit_glm_logit) == TRUE) {
  print("Correct, the glm with a family of binomial is a logistic regression")
}

fit_glm <- glm(blood.pressure ~ sex)
if (isFitLogit(fit_glm) == FALSE) {
  print("Correct, the glm without logit as a family is not a logistic regression")
}
Description

This function is a more specialized version of the `termplot()` function. It creates a plot with the spline against hazard ratio. The plot can additionally have indicator of variable density and have multiple lines.

Usage

```r
plotHR(
  models,
  term = 1,
  se = TRUE,
  cntrst = ifelse(inherits(models, "rms") || inherits(models[[1]], "rms"), TRUE, FALSE),
  polygon_ci = TRUE,
  rug = "density",
  xlab = "",
  ylab = "Hazard Ratio",
  main = NULL,
  xlim = NULL,
  ylim = NULL,
  col.term = "#08519C",
  col.se = "#DEEBF7",
  col.dens = grey(0.9),
  lwd.term = 3,
  lty.term = 1,
  lwd.se = lwd.term,
  lty.se = lty.term,
  x.ticks = NULL,
  y.ticks = NULL,
  ylog = TRUE,
  cex = 1,
  y_axis_side = 2,
  plot.bty = "n",
  axes = TRUE,
  alpha = 0.05,
  ...
)
```

Arguments

- `models`: A single model or a list() with several models
- `term`: The term of interest. Can be either the name or the number of the covariate in the model.
se  Boolean if you want the confidence intervals or not

cntrst  By contrasting values you can have the median as a reference point making it easier to compare hazard ratios.

polygon_ci  If you want a polygon as indicator for your confidence interval. This can also be in the form of a vector if you have several models. Sometimes you only want one model to have a polygon and the rest to be dotted lines. This gives the reader an indication of which model is important.

rug  The rug is the density of the population along the spline variable. Often this is displayed as a jitter with bars that are thicker & more common when there are more observations in that area or a smooth density plot that looks like a mountain. Use "density" for the mountain view and "ticks" for the jitter format.

xlab  The label of the x-axis

ylab  The label of the y-axis

main  The main title of the plot

xlim  A vector with 2 elements containing the upper & the lower bound of the x-axis

ylim  A vector with 2 elements containing the upper & the lower bound of the y-axis

col.term  The color of the estimate line. If multiple lines you can have different colors by giving a vector.

col.se  The color of the confidence interval. If multiple lines you can have different colors by giving a vector.

col.dens  The color of the density plot. Ignored if you’re using jitter

lwd.term  The width of the estimated line. If you have more than one model then provide the function with a vector if you want to have different lines for different width for each model.

lty.term  The type of the estimated line, see lty. If you have more than one model then provide the function with a vector if you want to have different line types for for each model.

lwd.se  The line width of your confidence interval. This is ignored if you’re using polygons for all the confidence intervals.

lty.se  The line type of your confidence interval. This is ignored if you’re using polygons for all the confidence intervals.

x.ticks  The ticks for the x-axis if you desire other than the default.

y.ticks  The ticks for the y-axis if you desire other than the default.

ylog  Show a logarithmic y-axis. Not having a logarithmic axis might seem easier to understand but it’s actually not really a good idea. The distance between HR 0.5 and 2.0 should be the same. This will only show on a logarithmic scale and therefore it is strongly recommended to use the logarithmic scale.

cex  Increase if you want larger font size in the graph.

y_axis_side  The side that the y axis is to be plotted, see axis() for details

plot.bty  Type of box that you want. See the bty description in graphical parameters (par). If bty is one of "o" (the default), "l", "7", "c", "u", or "]" the resulting box resembles the corresponding upper case letter. A value of "n" suppresses the box.
axes A boolean that is used to identify if axes are to be plotted
alpha The alpha level for the confidence intervals
... Any additional values that are to be sent to the plot() function

Value

The function does not return anything

Multiple models in one plot

The function allows for plotting multiple splines in one graph. Sometimes you might want to show more than one spline for the same variable. This allows you to create that comparison.

Examples of a situation where I’ve used multiple splines in one plot is when I want to look at a variables behavior in different time periods. This is another way of looking at the proportional hazards assumption. The Schoenfeld residuals can be a little tricky to look at when you have the splines.

Another example of when I’ve used this is when I’ve wanted to plot adjusted and unadjusted splines. This can very nicely demonstrate which of the variable span is mostly confounded. For instance - younger persons may exhibit a higher risk for a procedure but when you put in your covariates you find that the increased hazard changes back to the basic

robcov_alt

Robust covariance matrix based upon the 'sandwich'-package

Description

This is an alternative to the 'rms'-package robust covariance matrix that uses the 'sandwich' package vcovHC() function instead of the 'rms'-built-in estimator. The advantage being that many more estimation types are available.

Usage

robcov_alt(fit, type = "HC3", ...)

Arguments

fit The ols fit that
type a character string specifying the estimation type. See vcovHC() for options.
... You should specify type= followed by some of the alternative available for the vcovHC() function.

Value

model The fitted model with adjusted variance and df.residual set to NULL

Examples

# Generate some data
n <- 500
x1 <- runif(n) * 2
x2 <- runif(n)
y <- x1^3 + x2 + rnorm(n)

library(rms)
library(sandwich)
dd <- datadist(x1, x2, y)
org.op <- options(datadist = "dd")

# Main function
f <- ols(y ~ rcs(x1, 3) + x2)

# Check the bread
bread(f)
# Check the HC-matrix
timeSplitter

A function for splitting a time according to time periods

Description

If we have a violation of the cox proportional hazards assumption we need to split an individual’s followup time into several. See vignette(“timeSplitter”, package = "Greg") for a detailed description.

Usage

timeSplitter(
  data,
  by,
  time_var,
  event_var,
  event_start_status,
  time_related_vars,
  time_offset
)

Arguments

data The dataset that you want to split according to the time_var option.
by The time period that you want to split the dataset by. The size of the variable must be in proportion to the the time_var. The by variable can also be a vector for each time split, useful if the effect has large variations over time.
time_var The name of the main time variable in the dataset. This variable must be a numeric variable.
event_var The event variable
event_start_status The start status of the event status, e.g. "Alive"
time_related_vars A dataset often contains other variables that you want to update during the split, most commonly these are age or calendar time.
time_offset If you want to skip the initial years you can offset the entire dataset by setting this variable. See detailed description below.
Details

*Important note:* The time variables must have the same time unit. I.e. function can not dedu if all variables are in years or if one happens to be in days.

Value

data.frame with the split data. The starting time for each period is named `Start_time` and the ending time is called `Stop_time`. Note that the resulting event_var will now contain the time-splitted eventvar.

The time_offset - details

Both time_var and other variables will be adjusted by the time_offset, e.g. if we the time scale is in years and we want to skip the first 4 years we set the `time_offset = 4`. In the outputted dataset the smallest `time_var` will be 0. *Note:* 0 will not be included as we generally want to look at those that survived the start date, e.g. if a patient dies on the 4-year mark we would not include him/her in our study.

Examples

test_data <- data.frame(
id = 1:4,
time = c(4, 3.5, 1, 5),
event = c("alive", "censored", "dead", "dead"),
age = c(62.2, 55.3, 73.7, 46.3),
date = as.Date(c("2003-01-01", "2010-04-01", "2013-09-20", "2002-02-23")),
stringsAsFactors = TRUE
)
timeSplitter(test_data, .5,
  time_var = "time",
  time_related_vars = c("age", "date"),
  event_var = "event")
