glm4, very similarly as standard R's glm() is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

It is more general, as it fits linear, generalized linear, non-linear and generalized nonlinear models.

Usage

```
glm4(formula, family, data, weights, subset, na.action,
     start = NULL, etastart, mustart, offset,
     sparse = FALSE, drop.unused.levels = FALSE, doFit = TRUE,
     control = list(...),
     model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...)
```

Arguments

- **formula**: an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
- **family**: a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See family for details of family functions.)
- **data**: an optional data frame, list or environment (or object coercible by `as.data.frame` to a data frame) containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which glm is called.
- **weights**: an optional vector of 'prior weights' to be used in the fitting process. Should be NULL or a numeric vector.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
na.action  a function which indicates what should happen when the data contain NAs. The
default is set by the na.action setting of options, and is na.fail if that is
unset. The ‘factory-fresh’ default is na.omit. Another possible value is NULL,
no action. Value na.exclude can be useful.

start, etastart, mustart
starting values for the parameters in the linear predictor, the predictor itself and
for the vector of means.

offset
can be used to specify an a priori known component to be included in the
linear predictor during fitting. This should be NULL or a numeric vector of length
equal to the number of cases. One or more offset terms can be included in the
formula instead or as well, and if more than one is specified their sum is used.
See model.offset.

sparse
logical indicating if the model matrix should be sparse or not.

drop.unused.levels
used only when sparse is TRUE: Should factors have unused levels dropped?
(This used to be true, implicitly in the first versions up to July 2010; the default
has been changed for compatibility with R’s standard (dense) model.matrix().

dofit
logical indicating if the model should be fitted (or just returned unfitted).

control
a list with options on fitting; currently passed unchanged to (hidden) function
IRLS().

model, x, y
currently ignored; here for back compatibility with glm.

contrasts
passed to model.Matrix(..., contrasts.arg = contrasts), see its document-
tation.

... potentially arguments passed on to fitter functions; not used currently.

Value
an object of class glpModel.

See Also

glm() the standard R function;

lm.fit.sparse() a sparse least squares fitter.

The resulting class glpModel documentation.

Examples

### All the following is very experimental -- and probably will change: -------

data(CO2, package="datasets")

## dense linear model
str(glm4(uptake ~ 0 + Type*Treatment, data=CO2, doFit = FALSE), 4)

## sparse linear model
str(glm4(uptake ~ 0 + Type*Treatment, data=CO2, doFit = FALSE, sparse = TRUE), 4)

## From example(glm): -------------------
## Dobson (1990) Page 93: Randomized Controlled Trial :

```r
str(trial <- data.frame(counts=c(18,17,15,20,10,20,25,13,12),
  outcome=gl(3,1,9,labels=LETTERS[1:3]),
  treatment=gl(3,3,labels=letters[1:3])))
```

```r
glm.D93 <- glm(counts ~ outcome + treatment, family=poisson, data=trial)
summary(glm.D93)
c.glm <- unname(coef(glm.D93))
glmM <- glm4(counts ~ outcome + treatment, family = poisson, data=trial)
glmM2 <- update(glmM, quick = FALSE) # slightly more accurate
glmM3 <- update(glmM, quick = FALSE, finalUpdate = TRUE)
  # finalUpdate has no effect on 'coef'
stopifnot( identical(glmM2@pred@coef, glmM3@pred@coef),
  all.equal(glmM@pred@coef, c.glm, tolerance=1e-7),
  all.equal(glmM2@pred@coef, c.glm, tolerance=1e-12))
```

## Watch the iterations --- and use no intercept --> more sparse X
### 1) dense generalized linear model
```r
glmM <- glm4(counts ~ 0+outcome + treatment, poisson, trial,
  verbose = TRUE)
```
### 2) sparse generalized linear model
```r
glmS <- glm4(counts ~ 0+outcome + treatment, poisson, trial,
  verbose = TRUE, sparse = TRUE)
```

```r
str(glmS, max.lev = 4)
stopifnot( all.equal(glmM@pred@coef, glmS@pred@coef),
  all.equal(glmM@pred@Vtr, glmS@pred@Vtr) )
```

### A Gamma example, from McCullagh & Nelder (1989, pp. 300-2)
```r
clotting <- data.frame(u = c(5,10,15,20,30,40,60,80,100),
  lot1 = c(118,58,42,35,27,25,21,19,18),
  lot2 = c(69,35,26,21,18,16,13,12,12))
str(gMN <- glm4(lot1 ~ log(u), data=clotting, family=Gamma, verbose=TRUE))
glm. <- glm(lot1 ~ log(u), data=clotting, family=Gamma)
stopifnot( all.equal(gMN@pred@coef, unname(coef(glm.)), tolerance=1e-7) )
```

---

### glpModel-class

#### Class "glpModel" of General Linear Prediction Models

#### Description

The class "glpModel" conceptually contains a very large class of "General Linear Prediction Models".

Its `resp` slot (of class "respModule") may model linear, non-linear, generalized linear and non-linear generalized response models.

#### Objects from the Class

Objects can be created by calls of the form `new("glpModel", ...), but typically rather are returned by our modeling functions, e.g., `glm4()`.
Slots

resp: a "respModule" object.

pred: a "predModule" object.

Extends

Class "Model", directly.

Methods

coeff signature(object = "glpModel"): extract the coefficient vector $\beta$ from the object.

fitted signature(object = "glpModel"): fitted values; there may be several types, corresponding to the residuals, see there (below).

residuals signature(object = "glpModel"): residuals, depending on the type of the model, there are several types of residuals and correspondingly residuals, see residuals.glm from the stats package.

See Also

glm4() returns fitted glpModel objects.

The constituents of this class are respModule and predModule, both of which have several sub classes.

Examples

showClass("glpModel")

## Use example(glm4) or see help(glm4) for many more examples.

---

**lm.fit.sparse**

*Fitter Function for Sparse Linear Models*

Description

A basic computing engine for sparse linear least squares regression.

Note that the exact interface (arguments, return value) currently is experimental, and is bound to change. Use at your own risk!

Usage

```r
lm.fit.sparse(x, y, w = NULL, offset = NULL,
method = c("qr", "cholesky"),
tol = 1e-7, singular.ok = TRUE, order = NULL,
transpose = FALSE)
```
Arguments

- `x` *sparse* design matrix of dimension `n * p`, i.e., an R object of a class extending `dsparseMatrix`; typically the result of `sparse.model.matrix`.
- `y` vector of observations of length `n`, or a matrix with `n` rows.
- `w` vector of weights (length `n`) to be used in the fitting process. Weighted least squares is used with weights `w`, i.e., `sum(w * e^2)` is minimized.

**Not yet implemented!**

- `offset` numeric of length `n`). This can be used to specify an *a priori* known component to be included in the linear predictor during fitting.
- `method` a character string specifying the (factorization) method. Currently, "qr" or "cholesky".
- `tol` [for back-compatibility only; unused:] tolerance for the `qr` decomposition. Default is 1e-7.
- `singular.ok` [for back-compatibility only; unused:] logical. If FALSE, a singular model is an error.
- `order` integer or NULL, for `method == "qr"`, will determine how the fill-reducing ordering (aka permutation) for the "symbolic" part is determined (in `cs_amd()`), with the options
  - 0: natural,
  - 1: Chol,
  - 2: LU, and
  - 3: QR,

  where 3 is the default.
- `transpose` logical; if true, use the transposed matrix `t(x)` instead of `x`.

Value

Either a single numeric vector or a list of four numeric vectors.

See Also

- `glm4` is an alternative (much) more general fitting function.
- `sparse.model.matrix` from the `Matrix` package; the non-sparse function in standard R’s package `stats`: `lm.fit()`.

Examples

```r
dd <- expand.grid(a = as.factor(1:3),
  b = as.factor(1:4),
  c = as.factor(1:2),
  d= as.factor(1:8))
n <- nrow(dd <- dd[,rep(seq_len(nrow(dd)), each = 10), ])
set.seed(17)
dM <- cbind(dd, x = round(rnorm(n), 1))
## randomly drop some
```
Create a `respModule` object

**Description**

Create a `respModule` object, which could be from a derived class such as `glmRespMod` or `nlsRespMod`.

**Usage**

```r
mkRespMod(fr, family = NULL, nlenv = NULL, nlmod = NULL)
```
Arguments

- **fr**: a model frame, usually created by a call to `model.frame`.
- **family**: an optional glm `family` object (`glmRespMod` objects only).
- **nlenv**: an environment for evaluation of the nonlinear model, `nlmod` (`nlsRespMod` objects only).
- **nlmod**: the nonlinear model function, as a function call (`nlsRespMod` objects only).

Details

The internal representation of a statistical model based on a linear predictor expression is derived from a `formula` expression and a data argument, possibly supplemented with a `family` object and/or a nonlinear model expression. The steps to obtain this representation usually involve calls to `model.frame` and to `model.matrix` or `model.Matrix`, which encapsulate important parts of this process. This function encapsulates other operations related to weights and offsets and to the model family to create a `respModule` object.

Value

an object of a class inheriting from `respModule`.

See Also

The `respModule` class description.

Examples

```r
## see help("glmModel-class")
```

---

Model-class

Mother Class "Model" of all S4 Models

Description

Class "Model" is meant to be the mother class of all (S4) model classes. As some useful methods are already defined for "Model" objects, derived classes inherit those “for free”.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

- **call**: the `call` which generated the model.
- **fitProps**: a list; must be named, i.e., have unique `names`, but can be empty.

  When the main object is a fitted model, the list will typically have components such as `iter` (non-negative integer) and `convergenece` (logical typically).
model.Matrix

Methods

**formula** signature(x = "Model"): extract the model formula - if there is one, or **NULL**.

**update** signature(object = "Model"): Update the model with a new formula, new data, .... etc.

This semantically equivalent (and as R function almost identical) to the standard **update** (package **stats**).

See Also

the **glpModel** class in package **MatrixModels** which extends this class.

Examples

showClass("Model")

---

**model.Matrix**  
*Construct Possibly Sparse Design or Model Matrices*

Description

model.Matrix creates design matrix, very much like the standard R function **model.matrix**, however returning a dense or sparse object of class **modelMatrix**.

Usage

model.Matrix(object, data = environment(object),
contrasts.arg = NULL, xlev = NULL,
sparse = FALSE, drop.unused.levels = FALSE, ...)

Arguments

- **object**: an object of an appropriate class. For the default method, a model **formula** or a **terms** object.
- **data**: a data frame created with **model.frame**. If another sort of object, **model.frame** is called first.
- **contrasts.arg**: A list, whose entries are values (numeric matrices or character strings naming functions) to be used as replacement values for the **contrasts** replacement function and whose names are the names of columns of data containing **factors**.
- **xlev**: to be used as argument of **model.frame** if data has no "terms" attribute.
- **sparse** logical indicating if the result should be sparse (of class **sparseModelMatrix**), using **sparse.model.matrix()** (package **Matrix**).
- **drop.unused.levels** used only when sparse is TRUE: Should factors have unused levels dropped? (This used to be true, implicitly in the first versions up to July 2010; the default has been changed for compatibility with R’s standard (dense) **model.matrix()**.
- **...**: further arguments passed to or from other methods.
Details

model.Matrix() is a simple wrapper either (sparse = FALSE) around the traditional model.matrix() returning a "ddenseModelMatrix", or (sparse = TRUE) around sparse.model.matrix(), returning a "dsparseModelMatrix" object.

model.Matrix creates a design matrix from the description given in terms(object), using the data in data which must supply variables with the same names as would be created by a call to model.frame(object) or, more precisely, by evaluating attr(terms(object), "variables"). For more details, see model.matrix.

Value

an object inheriting from class modelMatrix, by default, ddenseModelMatrix.

See Also

model.matrix, sparse.model.matrix.

Examples

data(CO2, package="datasets")
class(sm <- model.Matrix(~ 0+Type*Treatment, data=CO2, sparse=TRUE))
class(dm <- model.Matrix(~ 0+Type*Treatment, data=CO2, sparse=FALSE))
stopifnot(dim(sm) == c(84,4), dim(sm) == dim(dm), all(sm == dm))

Description

The class "modelMatrix" and notably its subclass "dsparseModelMatrix" are used to encode additional information, analogously to what the standard R function model.matrix() returns.

Objects from the Classes

Only "dsparseModelMatrix" and "ddenseModelMatrix" are "actual" (aka non-virtual) classes. For these, objects can be created by calls of the form new("dsparseModelMatrix", x, assign, contrast), where x is a dgCMatrix classed object.

Slots

The "modelMatrix" mother class contains Matrix plus two extra slots,

assign: "integer" vector of length ncol(.), coding the variables which make up the matrix columns, see model.matrix.

contrasts: a named list of contrasts, as in model.matrix().

Dim: integer vector of length two with the matrix dimensions.

Dimnames: list of length two, the dimnames(.) of the matrix.
whereas the (current only) actual classes "d*ModelMatrix", have an at least an additional (numeric slot "x". E.g., "dsparseModelMatrix" has the additional slots
i,p: row number and “pointer” integer vectors, see class “dgCMatrix”.
x: "numeric" vector of non-zero entries.
Factors: a (possibly empty) list of factorizations.

Extends
"dsparseModelMatrix" extends class "dgCMatrix" directly,
"ddenseModelMatrix" extends class "dgeMatrix" directly.

Methods

show signature(object = "modelMatrix"): show(.) the matrix, but also the assign and contrasts slots.

print signature(x = "modelMatrix"): as show(), however (via ...) allowing to pass further arguments for printing the matrix.

Author(s)
Martin Maechler

See Also

sparse.model.matrix will return a "dsparseModelMatrix" object. model.Matrix which is a simple wrapper around the traditional model.matrix and returns a "ddenseModelMatrix" object.

Examples

showClass("modelMatrix")
showClass("dsparseModelMatrix")

## see example(model.Matrix)
Slots

The virtual class "predModule" and its two subclasses all have slots

X: a modelMatrix.

coef: "numeric" coefficient vector of length ncol(.) := p.

Vtr: "numeric" vector of length p, to contain \( V' r \) ("V transposed r").

fac: a representation of a triangular factor, the Cholesky decomposition of \( V' V \).

The actual classes "dPredModule" and "sPredModule" specify specific (sub) classes for the two
non-trivial slots,

X: a "ddenseModelMatrix" or "dsparseModelMatrix", respectively.

fac: For the "dpredModule" class this factor is a Cholesky object. For the "spredModule" class
it is of class CHMfactor.

Methods

coerce signature(from = "ddenseModelMatrix", to = "predModule"): Creates a "dPredModule"
object.

coerce signature(from = "dsparseModelMatrix", to = "predModule"): Creates an "sPredModule"
object.

Author(s)

Douglas Bates

See Also

model.Matrix() which returns a "ddenseModelMatrix" or "dsparseModelMatrix" object, de-
pending if its sparse argument is false or true. In both cases, the resulting "modelMatrix" can
then be coerced to a sparse or dense "predModule".

Examples

showClass("dPredModule")
showClass("sPredModule")

## see example(model.Matrix)
Aliases for Model Extractors

Description

Aliases for model extractors; it is an old S and R tradition to have aliases for these three model extractor functions:

- resid() equivalent to residuals().
- fitted.values() equivalent to fitted().
- coefficients() equivalent to coef().

We provide S4 generics and methods for these.

Methods

- **resid** signature(object = "ANY"): return the residuals; this is a rarely used alias for residuals().
- **fitted.values** signature(object = "ANY"): return the fitted values; this is a rarely used alias for fitted().
- **coefficients** signature(object = "ANY"): return the coefficients of a model; this is a rarely used alias for coef().

See Also

residuals; Methods for general information about formal (S4) methods.

"respModule" and derived classes

Description

The "respModule" class is the virtual base class of response modules for glpModel model objects. Classes that inherit from "respModule" include glmRespMod, for generalized linear models, nlsRespMod, for nonlinear models and nglmRespMod for generalized nonlinear models.

Objects from the Class

Objects from these classes are usually created with mkRespMod as part of an glpModel object returned by model-fitting functions such as the hidden function glm4.
Slots

mu: Fitted mean response.

offset: offset in the linear predictor – always present even if it is a vector of zeros. In an nlsRespMod object the length of the offset can be a multiple of the length of the response.

sqrtXwt: the matrix of weights for the model matrices, derived from the sqrtwrt slot.

sqrtwrt: Numeric vector of the square roots of the weights for the residuals. For respModule and nlsRespMod objects these are constant. For glmRespMod and nglmRespMod objects these are updated at each iteration of the iteratively reweighted least squares algorithm.

weights: Prior weights – always present even when it is a vector of ones.

y: Numeric response vector.

family: a glm family, see family for details - glmRespMod objects only.

eta: numeric vector, the linear predictor that is transformed to the conditional mean via the link function - glmRespMod objects only.

n: a numeric vector used for calculation of the aic family function (it is really only used with the binomial family but we need to include it everywhere) - glmRespMod objects only.

nlenv: an environment in which to evaluate the nonlinear model function - nlsRespMod objects only.

nlmod: an unevaluated call to the nonlinear model function - nlsRespMod objects only.

pnames: a character vector of parameter names - nlsRespMod objects only.

Methods

fitted signature(object = "respModule"): fitted values; there may be several types, corresponding to the residuals, see there (below).

residuals signature(object = "respModule"): residuals, depending on the type of the model, there are several types of residuals and correspondingly residuals, see residuals.glm from the stats package. Because many of these types of residuals are identical except for objects that inherit from "glmRespMod", a separate method is defined for this subclass.

See Also

mkRespMod

Examples

showClass("respModule")
showClass("glmRespMod")
showClass("nlsRespMod")
**Description**

Update any internal structures associated with sqrtXwt and the weighted residuals. The "V" matrix is evaluated from X using the sqrtXwt matrix and a Vtr vector is calculated.

**Usage**

```r
reweightPred(predM, sqrtXwt, wtres, ...)
```

**Arguments**

- `predM`: a predictor module
- `sqrtXwt`: the sqrtXwt matrix
- `wtres`: the vector of weighted residuals
- `...`: potentially further arguments used in methods; not used currently.

**Value**

updated predM

**Methods**

- `signature(predM = "dPredModule", sqrtXwt = "matrix", wtres = "numeric")` ..
- `signature(predM = "sPredModule", sqrtXwt = "matrix", wtres = "numeric")` ..

**Examples**

```r
## TODO
```

---

**solveCoef**  
*Solve for the Coefficients or Coefficient Increment*

**Description**

The squared length of the intermediate solution is attached as an attribute of the returned value.

**Usage**

```r
solveCoef(predM, ...)
```
Arguments

predM prediction module, i.e. from class predModule.
...
potentially further arguments used in methods; not used currently.

Value
coefficient vector or increment of coef.-vector.

Methods

signature(predM = "dPredModule") ..
signature(predM = "sPredModule") ..

Examples

## TODO

---

updateMu  

*Update 'mu', the Fitted Mean Response*

Description

Updates the mean vector $\mu$ given the linear predictor $\gamma$. Evaluate the residuals and the weighted sum of squared residuals.

Usage

updateMu(respM, gamma, ...)

Arguments

respM a response module, see the respModule class.
gamma the value of the linear predictor before adding the offset
...
potentially further arguments used in methods; not used currently.

Details

Note that the offset is added to the linear predictor before calculating mu.

The sqrtXwt matrix can be updated but the sqrtwrt should not be in that the weighted sum of squared residuals should be calculated relative to fixed weights. Reweighting is done in a separate call.

Value

updated respM
updateWts

Methods
signature(respM = "glmRespMod", gamma = "numeric") ..
signature(respM = "nglmRespMod", gamma = "numeric") ..
signature(respM = "nlsRespMod", gamma = "numeric") ..
signature(respM = "respModule", gamma = "numeric") ..

See Also
The respModule class (and specific subclasses); glm4.

Examples
## TODO

updateWts

Update the Residual and X Weights - Generic and Methods

Description
Update the residual weights sqrtrwt and X weights sqrtXwt.

Usage
updateWts(respM, ...)

Arguments
respM a response module, see the respModule class.
... potentially further arguments used in methods; not used currently.

Value
updated response module.

Methods
signature(respM = "glmRespMod") ..
signature(respM = "respModule") ..

Examples
