Package ‘PTXQC’

March 11, 2024

Type  Package
Title  Quality Report Generation for MaxQuant and mzTab Results
Version  1.1.1
Date  2024-03-11
Author  Chris Bielow [aut, cre],
        Juliane Schmachtenberg [ctb],
        Swenja Wagner [ctb],
        Patricia Scheil [ctb],
        Tom Waschischek [ctb],
        Guido Mastrobuoni [dtc, rev]
Maintainer  Chris Bielow <chris.bielow@bsc.fu-berlin.de>
Description  Generates Proteomics (PTX) quality control (QC) reports for shotgun LC-
             MS data analyzed with the MaxQuant software suite (from .txt files) or mzTab files (ideally from OpenMS 'QualityControl' tool).
             Reports are customizable (target thresholds, subsetting) and available in HTML or PDF format.
             Published in J. Proteome Res., Proteomics Quality Control: Quality Control Software for MaxQuant Results (2015)
             <doi:10.1021/acs.jproteome.5b00780>.
SystemRequirements  pandoc (http://pandoc.org) for building Vignettes and output reports as HTML
Depends  R (>= 3.3.0)
Imports  data.table, ggplot2 (>= 2.2), gg dendro, grid, gridExtra, grDevices, gtable, htmlTable, knitr (>= 1.10), magrittr, methods, plyr, R6, R6P, RColorBrewer, reshape2, rmarkdown, rmzqc (>= 0.5.0), seqinr, stats, utils, UpSetR, xml2, yaml
Suggests  testthat
VignetteBuilder  knitr
License  BSD_3_clause + file LICENSE
Encoding  UTF-8
RoxygenNote  7.3.1

PTXQC-package

PTXQC: A package for computing Quality Control (QC) metrics for Proteomics (PTX)

Description

The following sections describe the main components:

Input

Valid input data are either the files from MaxQuant’s .txt folder (all versions from MaxQuant >= 1.0 upwards are supported) or a single mzTab file. All mzTab files will work, but most metrics can be obtained from OpenMS’ mzTab as produced by the QualityControl TOPP tool (from OpenMS 2.5 onwards).
Important functions

The central function of this package is called `createReport` and it accepts either MaxQuant or mzTab data, along with a configuration (optional). There is a parser for mzTab `MzTabReader` and MaxQuant txt files `MQDataReader`, as well as a plethora of QC metrics derived from a common `qcMetric` class and scoring functions `qual...`, e.g. `qualGaussDev`.

Configuration

The user can modify the behaviour of PTXQC, e.g. to enable/disable certain metrics or change scoring thresholds, via a YAML object/file. By default a Yaml file is written automatically side-by-side to the input files upon running PTXQC for the first time on a particular input. A custom Yaml object can be passed to the main `createReport` function for customization. Use `yaml::yaml.load_file(input = 'myYAML.yaml')` to load an existing file and pass the Yaml object along.

Output

Either a PDF and/or Html report which contains QC plots and a description of the metrics.

alignmentCheck

Verify an alignment by checking the retention time differences of identical peptides across Raw files

Description

The input is a data frame containing feature evidence with corrected retention times, e.g. a 'calibrated.retention.time' column.

Usage

```
alignmentCheck(data, referenceFile)
```

Arguments

- `data` A data.frame with columns 'calibrated.retention.time', 'id', 'modified.sequence', 'charge', 'raw.file' and 'fraction' (if present)
- `referenceFile` A raw file name as occurring in data$raw.file, serving as alignment reference (when no fractions are used).
Details

Note that this function must be given real MS/MS identifications only (type "MULTI-MSMS") in order to work correctly!

For each peptide sequence (and charge) in the reference Raw file, this function looks up the already calibrated retention time difference of the same feature in all other files. For every comparison made, we report the RT difference. If alignment worked perfectly, the differences are very small (<1 min).

An 'id' column must be present, to enable mapping the result of this function to the original data frame.

A reference Raw file can be identified using 'findAlignReference()'. If Maxquants experimental design included pre-fractionation, a column named 'fraction' should be given and 'referenceFile' should be empty. This function will pick the one Raw file for each fraction (the first in order) to use as reference. Only the immediately neighbouring fractions will be matched to this reference.

Value

A data.frame containing the RT diff for each feature found in a Raw file and the reference.

---

### appendEnv

Add the value of a variable to an environment (fast append)

**Description**

The environment must exist, and its name must be given as string literal in 'env_name'! The value of the variable 'v' will be stored under the name given in 'v_name'. If 'v_name' is not given, a variable name will be created by increasing an internal counter and using the its value padded with zeros as name (i.e., "0001", "0002" etc).

**Usage**

`appendEnv(env_name, v, v_name = NULL)`

**Arguments**

- `env_name`: String of the environment variable
- `v`: Value to be inserted
- `v_name`: String used as variable name. Automatically generated if omitted.

**Value**

Always TRUE
assembleMZQC

Collects all 'mzQC' members from each entry in lst_qcMetrics and stores them in an overall mzQC object, which can be written to disk (see writeMZQC()) or augmented otherwise.

Usage

assembleMZQC(lst_qcMetrics, raw_file_mapping)

Arguments

lst_qcMetrics A list of qcMetric objects which have their mzQC member populated with "MzQCrunchQuality" and/or "MzQCsetQuality" objects

raw_file_mapping A data.frame with cols 'from', 'to' and maybe 'best.effort' (if shorting was unsuccessful), as e.g. obtained by a FilenameMapper$raw_file_mapping

Value

An MzQCmzQC object (root object of an mzQC document)

assignBlocks Assign set numbers to a vector of values.

Description

Each set has size set_size (internally optimized using correctSetSize), holding values from 'values'. This gives n such sets and the return value is just the set index for each value.

Usage

assignBlocks(values, set_size = 5, sort_values = TRUE)

Arguments

values Vector of values

set_size Number of distinct values allowed in a set

sort_values Before assigning values to sets, sort the values?
BoxplotCompare

Value

Vector (same length as input) with set numbers

Examples

```r
#library(PTXQC)
assignBlocks(c(1:11, 1), set_size = 3, sort_values = FALSE)
## --> 1 1 1 2 2 2 3 3 3 4 4 1
```

---

Boxplots - one for each condition (=column) in a data frame.

Description

Given a data.frame with two/three columns in long format (name, value, [contaminant]; in that order), each group (given from 1st column) is plotted as a bar. Contaminants (if given) are separated and plotted as yellow bars.

Usage

```r
boxplotCompare(
  data,
  log2 = TRUE,
  ylab = "intensity",
  mainlab = ylab,
  sublab = "",
  boxes_per_page = 30,
  abline = NA,
  coord_flip = TRUE,
  names = NA
)
```

Arguments

- **data**: Data frame in long format with numerical expression data
- **log2**: Apply log2 to the data (yes/no)
- **ylab**: Label on Y-axis
- **mainlab**: Main title
- **sublab**: Sub title
- **boxes_per_page**: Maximum number of boxplots per plot. Yields multiple plots if more groups are given.
- **abline**: Draw a horizontal green line at the specified y-position (e.g. to indicate target median values)
- **coord_flip**: Exchange Y and X-axis for better readability
- **names**: An optional data.frame(long=.., short=..), giving a renaming scheme (long->short) for the 'name' column
Details

Boxes are shaded: many NA or Inf lead to more transparency. Allows to easily spot sparse groups

Value

List of ggplot objects

brewer.pal.Safe

Return color brew palettes, but fail hard if number of requested colors is larger than the palette is holding.

Description

Internally calls 'brewer.pal(n, palette)', checking 'n' beforehand.

Usage

brewer.pal.Safe(n = 3, palette = "Set1")

Arguments

n Number of colours
palette Name of palette (e.g. "Set1")

Value

character vector of colors

byX

Calls FUN on a subset of data in blocks of size 'subset_size' of unique indices.

Description

One subset consists of 'subset_size' unique groups and thus of all rows which in 'data' which have any of these groups. The last subset might have less groups, if the number of unique groups is not dividable by subset_size.

Usage

byX(data, indices, subset_size = 5, FUN, sort_indices = TRUE, ...)
**Arguments**

- **data**
  Data.frame whose subsets to use on FUN
- **indices**
  Vector of group assignments, same length as nrow(data)
- **subset_size**
  Number of groups to use in one subset
- **FUN**
  Function applied to subsets of data
- **sort_indices**
  Sort groups (by their sorted character(!) names) before building subsets
- ... More arguments to FUN

**Details**

FUN is applied on each subset.

**Value**

list of function result (one entry for each subset)

**Examples**

```r
byX(data.frame(d=1:10), 1:10, 2, sum)
```

---

**byXflex**

*Same as byX, but with more flexible group size, to avoid that the last group has only a few entries (<50% of desired size).*

**Description**

The 'subset_size' param is internally optimized using `correctSetSize` and then byX is called.

**Usage**

```r
byXflex(data, indices, subset_size = 5, FUN, sort_indices = TRUE, ...)
```

**Arguments**

- **data**
  Data.frame whose subset to use on FUN
- **indices**
  Vector of group assignments, same length as nrow(data)
- **subset_size**
  Ideal number of groups to use in one subset – this can be changed internally, from 75%-150%
- **FUN**
  Function applied to subsets of data
- **sort_indices**
  Groups are formed by their sorted character(!) names
- ... More arguments to FUN
checkEnglishLocale

Value

list of function result (one entry for each subset)

Examples

stopifnot(
  byXflex(data.frame(d=1:10), 1:10, 2, sum, sort_indices = FALSE) ==
  c(3, 7, 11, 15, 19)
)

When MaxQuant is run with a wrong locale (i.e. the decimal separator is not a '.', but a ','), then MaxQuant results are plainly wrong and broken. The can be detected by, e.g. checking for negative charge annotation.

checkEnglishLocale(df_evd)

Arguments

df_evd Evidence table from which we only need the 'charge' column

computeMatchRTFractions

Combine several data structs into a final picture for segmentation incurred by 'Match-between-runs'.

qMBRSeg_Dist_inGroup might be empty if there are only singlets (transferred and genuine), but then the scores will be pretty boring as well (100)

computeMatchRTFractions(qMBR, qMBRSeg_Dist_inGroup)
**correctSetSize**

**Arguments**

- `qMBR`: A data.frame as computed by peakSegmentation()
- `qMBRSeg_Dist_inGroup`: A data.frame as computed by inMatchWindow()

**Value**

A data.frame which details the distribution of singlets and pairs (inRT and outRT) for each Raw file and genuine vs. all

---

**correctSetSize**

Re-estimate a new set size to split a number of items into equally sized sets.

**Description**

This is useful for plotting large datasets where multiple pages are needed. E.g. you know that you need 101 barplots, but you only want to fit about 25 per page. Naively one would now do five plots, with the last one only containing a single barplot. Using this function with `correctSetSize(101, 25)` would tell you to use 26 barplots per page, so you end up with four plots, all roughly equally filled. It also works the other extreme case, where your initial size is chosen slightly too high, e.g. Sets of size 5 for just 8 items is too much, because we can reduce the set size to 4 and still need two sets but now they are much more equally filled (`correctSetSize(8, 5) == 4`).

**Usage**

```r
correctSetSize(item_count, initial_set_size)
```

**Arguments**

- `item_count`: Known number of items which need to assigned to sets
- `initial_set_size`: Desired number of items a single set should hold

**Details**

We allow for up to set sizes of 150% from default, to avoid the last set being sparse (we remove it and distribute to the other bins) 150 Once the number of sets is fixed, we distribute all items equally. E.g. 6 items & initial_set_size=5, would result in 2 bins (5 items, 1 item), but we’d rather have one bin of 6 items or 8 items & initial_set_size=5, would result in 2 bins (5+3 items), since the last set is more than half full, but we’d rather have 4+4

**Value**

re-estimated set size which a set should hold in order to avoid underfilled sets
createReport

Examples

```r
stopifnot(
  correctSetSize(8, 5) == 4
)
stopifnot(
  correctSetSize(101, 25) == 26
)
```

createReport

Create a quality control report (in PDF format).

Description

This is the main function of the package and the only thing you need to call directly if you are just interested in getting a QC report.

Usage

```r
createReport(
  txt_folder = NULL,
  mztab_file = NULL,
  yaml_obj = list(),
  report_filenames = NULL,
  enable_log = FALSE
)
```

Arguments

- **txt_folder**: Path to txt output folder of MaxQuant (e.g. "c:/data/Hek293/txt")
- **mztab_file**: Alternative to **txt_folder**, you can provide a single mzTab file which contains PSM, PEP and PRT tables
- **yaml_obj**: A nested list object with configuration parameters for the report. Useful to switch off certain plots or skip entire sections.
- **report_filenames**: Optional list with names (as generated by getReportFilenames). If not provided, will be created internally by calling getReportFilenames.
- **enable_log**: If TRUE all console output (including warnings and errors) is logged to the file given in **report_filenames$log_file**. Note: warnings/errors can only be shown in either the log **or** the console, not both!
createYaml

Details

You need to provide either a) the folder name of the 'txt' output, as generated by MaxQuant or an mzTab file or b) an mzTab file as generated by the OpenMS QualityControl TOPP tool (other mzTab files will probably not work)

Optionally, provide a YAML configuration object, which allows to (de)activate certain plots and holds other parameters. The yaml_obj is complex and best obtained by running this function once using the default (empty list). A full YAML configuration object will be written in the `txt` folder you provide and can be loaded using `yaml.load`.

The PDF and the config file will be stored in the given `txt` folder.

Value

List with named filename strings, e.g. $yaml_file, $report_file etc.

Note

You need write access to the txt/mzTab folder!

For updates, bug fixes and feedback please visit https://github.com/cbielow/PTXQC.

createYaml  Creates a yaml file storing the parameters that are used for creating the PTXQC report and returns these parameters as well as a list of available qc-Metrics objects.

Description

Valid parameters are: param_useMQPAR, add_fs_col, id_rate_bad, id_rate_great, pg_ratioLabIncThresh, param_PG_intThresh, param_EV_protThresh, param_EV_intThresh, param_EV_pepThresh, yaml_contaminants, param_EV_MatchingTolerance, param_evd_mbr, param_EV_PrecursorTolPPM, param_EV_PrecursorOutOfCalSD, param_EV_PrecursorTolPPMmainSearch, param_MSKMSScans_ionInjThresh, param_OutputFormats and param_PageNumbers

Please provide them as a list() of this format: list$parameter_name

Usage

createYaml(
  yc,
  param = list(),
  DEBUG_PTXQC = FALSE,
  txt_files = NULL,
  metrics = NULL
)

Arguments

yc
A yaml class object created by YAMLClass$new()

param
list of parameters sorted by names; if empty, will be populated with defaults

DEBUG_PTXQC
print some debugging information; default FALSE

txt_files
list of paths to MaxQuant files; if NULL, it is assumed that the parameters are for mzTab-mode

metrics
list of metric names that should be plotted; if NULL, will be populated with defaults

Value

list of parameters used for creating the report and list of qc-Metrics objects

CV

Coefficient of variation (CV)

Description

Computes sd(x) / mean(x)

Usage

CV(x)

Arguments

x
Vector of numeric values

Value

CV

darken

Make a color (given as name or in RGB) darker by factor $x = [0 = black, 1=unchanged]$

Description

Make a color (given as name or in RGB) darker by factor $x = [0 = black, 1=unchanged]$

Usage

darken(color, factor = 0.8)
Arguments

- **color**
  A color as understood by col2rgb

- **factor**
  Between 0 (make black) and 1 (leave color as is)

Value

darkened color

del0  
*Replace 0 with NA in a vector*

Description

Replace 0 with NA in a vector

Usage

del0(x)

Arguments

- **x**
  A numeric vector

Value

Vector of same size as 'x', with 0’s replaced by NA

delLCP  
*Removes the longest common prefix (LCP) from a vector of strings.*

Description

You should provide only unique strings (to increase speed). If only a single string is given, the empty string will be returned unless minOutputLength is set.

Usage

delLCP(x, min_out_length = 0, add_dots = FALSE)

Arguments

- **x**
  Vector of strings with common prefix

- **min_out_length**
  Minimal length of the shortest element of x after LCP removal [default: 0, i.e. empty string is allowed]. If the output would be shorter, the last part of the LCP is kept.

- **add_dots**
  Prepend output with ‘.’ if shortening was done.
**Value**

Shortened vector of strings

**Examples**

```r
delLCP(c("TK12345_H1"), min_out_length=0)
## ""

delLCP(c("TK12345_H1"), min_out_length=4)
## "5_H1"

delLCP(c("TK12345_H1"), min_out_length=4, add_dots = TRUE)
## ".5_H1"

delLCP(c("TK12345_H1", "TK12345_H2"), min_out_length=4)
## "5_H1" "5_H2"

delLCP(c("TK12345_H1", "TK12345_H2"), min_out_length=4, add_dots = TRUE)
## ".5_H1" ".5_H2"

delLCP(c("TK12345_H1", "TK12345_H2"), min_out_length=8)
## "12345_H1", "12345_H2"

delLCP(c("TK12345_H1", "TK12345_H2"), min_out_length=8, add_dots = TRUE)
## "TK12345_H1", "TK12345_H2" (unchanged, since '.' would add another two)

delLCP(c("TK12345_H1", "TK12345_H2"), min_out_length=60)
## "TK12345_H1", "TK12345_H2" (unchanged)

delLCP(c("TK12345_H1", "TK12345_H2"), min_out_length=60, add_dots = TRUE)
## "TK12345_H1", "TK12345_H2" (unchanged)
```

---

**delLCS**

Removes the longest common suffix (LCS) from a vector of strings.

**Description**

Removes the longest common suffix (LCS) from a vector of strings.

**Usage**

delLCS(x)

**Arguments**

- `x` Vector of strings with common suffix
Value

Shortened vector of strings

Examples

delLCS(c("TK12345_H1"))        ## ""
delLCS(c("TK12345_H1", "TK12345_H2"))        ## "TK12345_H1" "TK12345_H2"
delLCS(c("TK12345_H1", "TK12145_H1"))        ## "TK123" "TK121!"

FilenameMapper-class

Make sure to call $readMappingFile(some_file) if you want to support a user-defined file mapping. Otherwise, calls to $getShortNames() will create/augment the mapping for filenames.

Description

Make sure to call $readMappingFile(some_file) if you want to support a user-defined file mapping. Otherwise, calls to $getShortNames() will create/augment the mapping for filenames.

Fields

raw_file_mapping  Data.frame with columns 'from', 'to' and maybe 'best.effort' (if shorting was unsuccessful)
mapping.creation  how the current mapping was obtained (user or auto)
external.mapping.file  Filename of user-defined mapping file; only defined if readMappingFile() was called

Methods

getShortNamesStatic(raw.files, max_len, fallbackStartNr = 1) Static method: Shorten a set of Raw file names and return a data frame with the mappings. Mapping will have: $from, $to and optionally $best.effort (if shorting was unsuccessful and numbers had to be used)

• raw.files  Vector of Raw files.
• max_len  Maximal length of shortening results, before resorting to canonical names (file 1,...).
• fallbackStartNr  Starting index for canonical names.

Return Value:  data.frame with mapping.

Examples

a = FilenameMapper$new()
a$readMappingFile('filenamemapping.txt')
**findAlignReference**

_Return list of raw file names which were reported by MaxQuant as reference point for alignment._

---

**Description**

There is only one reference point which has '0' in 'retention.time.calibration' column in evidence.txt as corrected RT. This is true for most MaxQuant versions and also true for fractions. However, some evidence.txt files show 0.03 as an averaged minimum per Raw file. We use the raw.file with the smallest average as reference.

**Usage**

`findAlignReference(data)`

**Arguments**

- `data` The data.frame with columns 'retention.time.calibration' and 'raw.file'

**Details**

Note that MaxQuant uses a guide tree to align the Raw files, so the order of files does not influence the alignment. But the first file will always be used as reference point when reporting delta-RTs. And this file is also used by PTXQC as reference file vs all other files to find the real calibration function (see `alignmentCheck()`).

This function might return multiple raw file names (if MQ decides to change its mind at some point in the future). In this case the result should be treated with caution or (better) regarded as failure.

**Value**

List of reference raw files (usually just one)

---

**fixCalibration**

_Detect (and fix) MaxQuant mass recalibration columns, since they sometimes report wrong values._

---

**Description**

Returns a list of items for both diagnostics and possibly a fixed evidence data.frame. Also two strings with messages are returned, which can serve as user message for pre and post calibration status.
flattenList

Usage

```r
gfixCalibration(
  df_evd,
  df_idrate = NULL,
  tolerance_sd_PCutOutOfCal = 2,
  low_id_rate = 1
)
```

Arguments

- `df_evd`: Evidence data.frame with columns ()
- `df_idrate`: Data.frame from summary.txt, giving ID rates for each raw file (cols: "ms.ms.identified....", "fc.raw.file"). Can also be NULL.
- `tolerance_sd_PCutOutOfCal`: Maximal standard deviation allowed before considered 'failed'
- `low_id_rate`: Minimum ID rate in Percent before a Raw file is considered 'failed'

Value

- list of data (stats, affected_raw_files, df_evd, recal_message, recal_message_post)

---

flattenList

*Flatten lists of lists with irregular depths to just a list of items, i.e. a list of the leaves (if you consider the input as a tree).*

Description

Flatten lists of lists with irregular depths to just a list of items, i.e. a list of the leaves (if you consider the input as a tree).

Usage

```r
flattenList(x)
```

Arguments

- `x`: List of 'stuff' (could be lists or items or a mix)

Value

- A flat list
**getAbundanceClass**

Assign a relative abundance class to a set of (log10) abundance values

**Description**

Abundances (should be logged already) are grouped into different levels, starting from the smallest values ("low") to the highest values ("high"). Intermediate abundances are either assigned as "mid", or "low-mid". If the range is too large, only "low" and "high" are assigned, the intermediate values are just numbers.

**Usage**

getAbundanceClass(x)

**Arguments**

- **x** Vector of numeric values (in log10)

**Details**

Example: getAbundanceClass(c(12.4, 17.1, 14.9, 12.3)) ## –> factor(c("low", "high", "mid", "low"))

**Value**

Vector of factors corresponding to input with abundance class names (e.g. low, high)

---

**getECDF**

Estimate the empirical density and return it

**Description**

Estimate the empirical density and return it

**Usage**

getECDF(samples, y_eval = (1:100)/100)

**Arguments**

- **samples** Vector of input values (samples from the distribution)
- **y_eval** Vector of points where CDF is evaluated (each percentile by default)

**Value**

Data.frame with columns 'x', 'y'
Examples

```r
plot(getECDF(rnorm(1e4)))
```

---

**getFileEncoding**  
*Determine if a file is 'UTF-8' or 'UTF-8-BOM' (as of MQ2.4) or 'UTF-16BE' or 'UTF-16LE'*

**Description**  
Determine if a file is 'UTF-8' or 'UTF-8-BOM' (as of MQ2.4) or 'UTF-16BE' or 'UTF-16LE'

**Usage**  

```r
getFileEncoding(filename)
```

**Arguments**

- `filename`  
  Relative or absolute path to a file

**Value**  
"" if the file does not exist or is not readable

---

**getFragmentErrors**  
*Extract fragment mass deviation errors from a data.frame from msms.txt*

**Description**  
Given a data.frame as obtainable from a msms.txt with - a 'mass.analyzer' column which contains only a single value for the whole column - a ’mass.deviations.da.’ and (if available) ’mass.deviations.ppm.’ - a ’masses’ column (only required if ’mass.deviations.ppm.’ is unavailable and the mass.analyzer indicates hig-res data)

**Usage**  

```r
getFragmentErrors(x, recurse = 0)
```

**Arguments**

- `x`  
  Data frame in long format with numerical expression data
- `recurse`  
  Internal usage only. Leave at 0 when calling.
Details

Mass deviations are extracted from the columns, e.g. each cell containing values separated by semicolons is split into single values. The appropriate unit is chosen (Da or ppm, depending on ITMS or FTMS data). Also the fragmentation type can be used: CID indicates ITMS, HCD to FTMS. This is not 100

Sometimes, peptides are identified purely based on MS1, i.e. have no fragments. These will be ignored.

If ppm mass deviations are not available, errors in Da will be converted to ppm using the corresponding mass values.

Value

Data frame with mass errors ('msErr') and their 'unit' (Da or ppm) or NULL (if no fragments were given)

getHTMLTable

Create an HTML table with an extra header row

Description

Create an HTML table with an extra header row

Usage

getHTMLTable(data, caption = NA)

Arguments

data  A data.frame which serves as table
caption  A set of headlines, e.g. c("top line", "bottom line")

Value

table as html character string for cat()’ing into an html document

Examples

data = data.frame(raw.file = letters[1:4],
                  id.rate = 3:6)
getHTMLTable(data,
             caption = "some header line")
getMaxima

Find the local maxima in a vector of numbers.

**Description**

A vector of booleans is returned with the same length as input which contains TRUE when there is a maximum. Simply sum up the vector to get the number of maxima.

**Usage**

```
getMaxima(x, thresh_rel = 0.2)
```

**Arguments**

- `x` Vector of numbers
- `thresh_rel` Minimum relative intensity to maximum intensity of `x` required to be a maximum (i.e., a noise threshold). Default is 20%.

**Value**

Vector of bool’s, where TRUE indicates a local maximum.

**Examples**

```
r = getMaxima(c(1,0,3,4,5,0))
all(r == c(TRUE,FALSE,FALSE,FALSE,TRUE,FALSE))
getMaxima(c(1, NA, 3, 2, 3, NA, 4, 2, 5))
```

getMetaData

Extract meta information (orderNr, metric name, category) from a list of Qc metric objects

**Description**

Extract meta information (orderNr, metric name, category) from a list of Qc metric objects

**Usage**

```
getMetaData(lst_qcMetrics)
```

**Arguments**

- `lst_qcMetrics` List of qcMetrics
getMetricsObjects

Value

data.frame with columns 'name', 'order' and 'cat' (category)

getMetricsObjects  Get all currently available metrics

Description

Get all currently available metrics

Usage

getMetricsObjects(DEBUG_PTXQC = FALSE)

Arguments

DEBUG_PTXQC  Use qc objects from the package (FALSE) or from environment (TRUE/DEBUG)

Value

List of metric objects

getMQPARValue  Retrieve a parameter value from a mqpar.xml file

Description

If the file has the param, then return it as string. If the file is missing, warning is shown and NULL is returned. If the param (i.e. XML tag) is unknown or cannot be extracted, the program will quit (since this is a hard error). When multiple occurrences of the param are found (usually due to parameter groups), we test if the values are all identical. If so, the value is returned. If the values are different, a warning is emitted and NULL is returned unless 'allow_multiple = TRUE'

Usage

getMQPARValue(mqpar_filename, xpath, allow_multiple = FALSE)

Arguments

mqpar_filename  Filename (incl. absolute or relative path) to the mqpar.xml file
xpath  An XPath to extract the content of XML tag(s), e.g. '//firstSearchTol'
allow_multiple  If the XPath expression returns more than one value, all values must be identical (not allowing multiple different values) or 'stop()' is called
getPCA

Details

E.g. calling getMQPARValue("mqpar.xml", "/firstSearchTol") will look up the line <firstSearchTol>20</firstSearchTol> and return "20" (string!).

Value

The stored value as string(!)

getPCA

Create a principal component analysis (PCA) plot for the first two dimensions.

Description

Create a principal component analysis (PCA) plot for the first two dimensions.

Usage

getPCA(data, do_plot = TRUE, connect_line_order = NA, gg_layer)

Arguments

data Matrix(!) where each row is one high-dimensional point, with ncol dimensions, e.g. a mouse as an array of protein expressions. rownames(data) give classes for colouring (can be duplicates in matrices, as opposed to data.frames)
do_plot Show PCA plot? if ==2, then shows correlations plot as well
connect_line_order Connect points by lines, the order is given by this vector. Default: NA (no lines)

Value

[invisible] Named list with "PCA": The PCA object as returned by prcomp, access $x$ for PC values and "plots": list of plot objects (one or two)
getPeptideCounts

Extract the number of peptides observed per Raw file from an evidence table.

Description

Required columns are "fc.raw.file", "modified.sequence" and "is.transferred".

Usage

getPeptideCounts(df_evd)

Arguments

df_evd Data.frame of evidence.txt as read by MQDataReader

Details

If match-between-runs was enabled during the MaxQuant run, the data.frame returned will contain separate values for 'transferred' evidence plus an 'MBRgain' column, which will give the extra MBR evidence in percent.

Value

Data.frame with columns 'fc.raw.file', 'counts', 'category', 'MBRgain'

getProteinCounts

Extract the number of protein groups observed per Raw file from an evidence table.

Description

Required columns are "protein.group.ids", "fc.raw.file" and "is.transferred".

Usage

getProteinCounts(df_evd)

Arguments

df_evd Data.frame of evidence.txt as read by MQDataReader

Details

If match-between-runs was enabled during the MaxQuant run, the data.frame returned will contain separate values for 'transferred' evidence plus an 'MBRgain' column, which will give the extra MBR evidence in percent.
getQCHeatMap

Description

Each list entry is a data.frame with two columns. The first one contains the Raw file name (or the short version), and should be named 'raw.file' (or 'fc.getRaw.file'). The second column’s name must be an expression (see ?plotmath) and contains quality values in the range \([0,1]\). If values are outside this range, a warning is issued and values are cut to the nearest allowed value (e.g. '1.2' becomes '1'). List entries are merged and columns are ordered by name.

All substrings enclosed by 'X[0-9]*X.' will be removed (can be used for sorting columns). The resulting string is evaluated as an expression. E.g. parse(text = <colname>)

Usage

getQCHeatMap(lst_qcMetrics, raw_file_mapping)

Arguments

- lst_qcMetrics: List of QC Metric objects
- raw_file_mapping: Data.frame with 'from' and 'to' columns for name mapping to unify names from list entries

Details

To judge the overall quality of each raw file a summary column is added, values being the mean of all other columns per row.

Value

A ggplot object for printing
getReportFilenames  

Assembles a list of output file names, which will be created during reporting.

**Description**

You can combine **report_name_has_folder** (and **mzTab_filename** for mzTab files) to obtain report filenames which are even more robust to moving around (since they contain infixes of the mzTab filename and the folder), e.g. `report_HEK293-study_myProjects.html`, where the input was `mzTab_filename='HEK293-study.mzTab'` and `folder='c:/somePath/myProjects/'`.

**Usage**

```r
getReportFilenames(
  folder,
  report_name_has_folder = TRUE,
  mzTab_filename = NULL
)
```

**Arguments**

- **folder**: Directory where the MaxQuant output (txt folder) or the mzTab file resides
- **report_name_has_folder**: Boolean: Should the report files (html, pdf) contain the name of the deepest subdirectory in **txt_folder** which is not `txt`? Useful for discerning different reports in a PDF viewer. E.g. when flag is FALSE: `report_v0.91.0.html`; and `report_v0.91.0_bloodStudy.html` when flag is TRUE (and the txt folder is `.../bloodStudy/txt/` or `.../bloodStudy/`)
- **mzTab_filename**: If input is an mzTab, specify its name, so that the filenames can use its basename as infix E.g. when `mzTab_filename = 'HEK293-study.mzTab'` then the output will be `report_HEK293-study.html`. This allows to get reports on multiple mzTabs in the same folder without overwriting report results.

**Value**

**getRunQualityTemplate**

*Get an mzQC runQuality without actual metrics, but with full metadata*

**Description**

Get an mzQC runQuality without actual metrics, but with full metadata

**Usage**

```r
getRunQualityTemplate(fc.raw.file, raw_file_mapping)
```

**Arguments**

- `fc.raw.file`: For which run
- `raw_file_mapping`: A data.frame with cols ‘from’, ’to’ and maybe ’best.effort’ (if shorting was unsuccessful), as e.g. obtained by a FilenameMapper$raw_file_mapping

**Value**

An MzQCrunQuality object

---

**ggAxisLabels**

*Function to thin out the number of labels shown on an axis in GGplot*

**Description**

By default, 20 labels (or up to 40 see below) are shown. If the number of items is less than twice the number of desired labels, all labels will be shown (to avoid irregular holes for some labels). I.e. if n=20, and x has 22 entries, there would be only two labels removed, giving a very irregular picture. It only becomes somewhat regular if after any label there is at least one blank, i.e. at most half the entries are labeled. #’ Example: ## p is any ggplot object p + scale_y_discrete(breaks = ggAxisLabels) ## customize ’n’ my.ggAxisLabels = function(x) ggAxisLabels(x, n = 4) p + scale_y_discrete(breaks = my.ggAxisLabels)

**Usage**

```r
ggAxisLabels(x, n = 20)
```

**Arguments**

- `x`: Vector of labels (passed by GGplot)
- `n`: Number of labels to show

**Value**

Shortened version of ’x’
**ggText**

*Plot a text as graphic using ggplot2.*

**Description**

Plot a text as graphic using ggplot2.

**Usage**

```r
ggText(title, text, col = "black")
```

**Arguments**

- `title` The title of the plot
- `text` Centered text, can contain linebreaks
- `col` Colour of text (excluding the title)

**Value**

`ggplot` object

---

**grepv**

*Grep with values returned instead of indices.*

**Description**

The parameter 'value' should not be passed to this function since it is passed internally already.

**Usage**

```r
grepv(reg, data, ...)
```

**Arguments**

- `reg` regex param
- `data` container
- `...` other params forwarded to grep()

**Value**

Values of data which matched the regex

**Examples**

```r
grepv("x", c("abc", "xyz"))
## --> "xyz"
```
Description

The input is a data.frame containing feature evidence with corrected retention times, e.g. a 'calibrated.retention.time' column.

Usage

idTransferCheck(df_evd_all)

Arguments

df_evd_all  A data.frame with columns 'type', 'calibrated.retention.time', 'modified.sequence', 'charge', 'raw.file'

Details

Note that this function must be given MS/MS identifications of type "MULTI-MSMS" and "MSMS-MATCH". It will stop() otherwise.

We compare for each peptide sequence (and charge) the RT difference within groups of either genuine as well as mixed pairs. For every comparison made, we report the RT span If alignment worked perfectly, the span are very small (<1 min), for the mixed group, i.e. the pairs are accidentally split 3D peaks. Alignment performance has no influence on the genuine-only groups.

Note: We found early MaxQuant versions (e.g. 1.2.2.5) to have an empty 'modified.sequence' column for 'MULTI-MATCH' entries. The sequence which SHOULD be present is equal to the immediate upper row. This is what we use to guess the sequence. However, this relies on the data.frame not being subsetted before (we can sort using the 'id' column)!

Value

A data.frame containing the RT diff for each ID-group found in a Raw file (bg = genuine).

Description

For grouped peaks: separate them into in-width vs. out-width class.

Looking at groups only: Compute the fraction of 3D-peak pair groups per Raw file which have an acceptable RT difference after alignment using the result from 'idTransferCheck()', i.e. compute the fraction of groups which are within a certain RT tolerance.
**Usage**

inMatchWindow(data, df.allowed.deltaRT)

**Arguments**

- **data**: A data.frame with columns 'fc.raw.file', 'rtdiff_mixed', 'rtdiff_genuine'
- **df.allowed.deltaRT**: The allowed matching difference for each Raw file (as data.frame(fc.rawfile, m))

**Details**

Returned value is between 0 (bad) and 1 (all within tolerance).

**Value**

A data.frame with one row for each raw.file and columns 'raw.file' and score 'withinRT' (0-1)

---

**Description**

Count the number of chars of the longest common prefix

**Usage**

lcpCount(x)

**Arguments**

- **x**: Vector of strings with common prefix

**Value**

Length of LCP
LCS

*Compute longest common substring of two strings.*

**Description**

Implementation is very inefficient (dynamic programming in R) \(\rightarrow\) use only on small instances

**Usage**

```
LCS(s1, s2)
```

**Arguments**

- `s1` String one
- `s2` String two

**Value**

String containing the longest common substring

---

lcsCount

*Count the number of chars of the longest common suffix*

**Description**

Count the number of chars of the longest common suffix

**Usage**

```
lcsCount(x)
```

**Arguments**

- `x` Vector of strings with common suffix

**Value**

Length of LCS
LCSn

Find longest common substring from 'n' strings.

Description

Warning: greedy heuristic! This is not guaranteed to find the best solution (or any solution at all), since its done pairwise with the shortest input string as reference.

Usage

LCSn(strings, min_LCS_length = 0)

Arguments

strings
A vector of strings in which to search for LCS

min_LCS_length
Minimum length expected. Empty string is returned if the result is shorter

Value

longest common substring (or "" if shorter than min_LCS_length)

Examples

LCSn(c("1_abcde...",
  "2_abcd...",
  "x_abc..."))  ## --> ".abc"
LCSn(c("16_IMU008_CISPLA_E5_R11",
  "48_IMU008_CISPLA_P4_E7_R31",
  "60_IMU008_CISPLA_E7_R11"), 3)  ## -->" IMU008_CISPLA_"
LCSn(c("AAAAACBBBBB",
  "AAAAABBBBB",
  "AAAABBBBBEF",
  "AAAABBBBBDGH")) # --> "BBBBB"
LCSn(c("AAAAABBBB",
  "BBBXXDDD",
  "XXAAAADD") ) # --> fails due to greedy approach; should be "XX"

longestCommonPrefix

Get the longest common prefix from a set of strings.

Description

Input is converted to character (e.g. from factor) first.
Usage

longestCommonPrefix(strings)

Arguments

strings Vector of strings

Value

Single string - might be empty ("")

Examples

longestCommonPrefix(c("CBA.321", "CBA.77654", "")) ## ""
longestCommonPrefix(c("CBA.321", "CBA.77654", "CB")) ## "CB"
longestCommonPrefix(c("ABC.123", "ABC.456")) ## "ABC."
longestCommonPrefix(c("nothing", "in", "common")) ## ""

longestCommonSuffix Like longestCommonPrefix(), but on the suffix.

Description

Like longestCommonPrefix(), but on the suffix.

Usage

longestCommonSuffix(strings)

Arguments

strings Vector of strings

Value

Single string - might be empty ("")

Examples

longestCommonSuffix(c("123.ABC", "45677.ABC", "BC")) ## "BC"
longestCommonSuffix(c("123.ABC", "", "BC")) ## ""
longestCommonSuffix(c("123.ABC", "45677.ABC")) ## "ABC"
longestCommonSuffix(c("nothing", "in", "common")) ## ""
**modsToTable**

*Convert list of (mixed) modifications to a frequency table*

**Description**

Convert list of (mixed) modifications to a frequency table

**Usage**

```r
modsToTable(mod_list)
```

**Arguments**

- `mod_list`: A vector with modifications, each for a specific peptide. Multiple mods per entry are allowed, each separated by comma.

**Value**

A data.frame with ` modification_names` and `Freq` (0-100)

**Examples**

```r
modsToTable(c("Ox (M)",
              "Unmodified",
              "Ox (M),Acetyl (Prot N-term)",
              "2 Ox (M)",
              "Unmodified",
              "Unmodified"))
```

---

**modsToTableByRaw**

*Convert list of (mixed) modifications to a frequency table*

**Description**

Convert list of (mixed) modifications to a frequency table

**Usage**

```r
modsToTableByRaw(
  df_evd, 
  name_unmod = "Unmodified", 
  name_unmod_inverse = "Modified (total)"
)
```
mosaicize

Prepare a Mosaic plot of two columns in long format.

Description

Found at http://stackoverflow.com/questions/19233365/how-to-create-a-marimekko-mosaic-plot-in-ggplot2 Modified (e.g. to pass R check)

Usage

mosaicize(data)

Arguments

data A data.frame with exactly two columns

Details

Returns a data frame, which can be used for plotting and has the following columns: 'Var1' - marginalized values from 1st input column 'Var2' - marginalized values from 2nd input column 'Freq' - relative frequency of the combination given in [Var1, Var2] 'margin_var1' - frequency of the value given in Var1 'var2_height' - frequency of the value given in Var2, relative to Var1 'var1_center' - X-position when plotting (large sets get a larger share)
MQDataReader-class

Value

Data.frame

Examples

data = data.frame(raw.file = c(rep('file A', 100), rep('file B', 40)),
                charge = c(rep(2, 60), rep(3, 30), rep(4, 10),
                          rep(2, 30), rep(3, 7), rep(4, 3)))
mosaicize(data)

MQDataReader-class  S5-RefClass to read MaxQuant .txt files

Description

This class is used to read MQ data tables using MQDataReader::readMQ() while holding the internal raw file –> short raw file name mapping (stored in a member called 'fn_map') and updating/using it every time MQDataReader::readMQ() is called.

Arguments

file      (Relative) path to a MQ txt file.
filter    Searched for "C" and "R". If present, [c]ontaminants and [r]everse hits are removed if the respective columns are present. E.g. to filter both, filter = "C+R"
type      Allowed values are: "pg" (proteinGroups) [default], adds abundance index columns (*AbInd*, replacing 'intensity') "sm" (summary), splits into three row subsets (raw.file, condition, total) "ev" (evidence), will fix empty modified.sequence cells for older MQ versions (when MBR is active) "msms_scans", will fix invalid (negative) scan event numbers Any other value will not add/modify any columns
col_subset A vector of column names as read by read.delim(), e.g., spaces are replaced by dot already. If given, only columns with these names (ignoring lower/uppercase) will be returned (regex allowed) E.g. col_subset=c("^lfq.intensity.", "protein.name")
add_fs_col If TRUE and a column 'raw.file' is present, an additional column 'fc.raw.file' will be added with common prefix AND common substrings removed (simplifyNames) E.g. two rawfiles named 'OrbiXL_2014_Hek293_Control', 'OrbiXL_2014_Hek293_Treated' will give 'Control', 'Treated' If add_fs_col is a number AND the longest short-name is still longer, the names are discarded and replaced by a running ID of the form 'file <x>'), where <x> is a number from 1 to N. If the function is called again and a mapping already exists, this mapping is used. Should some raw.files be unknown (ie the mapping from the previous file is incomplete), they will be augmented
check_invalid_lines After reading the data, check for unusual number of NA's to detect if file was corrupted by Excel or alike
**LFQ_action**

[For type==’pg’ only] An additional custom LFQ column (’cLFQ...’) is created where zero values in LFQ columns are replaced by the following method: IFF(!) the corresponding raw intensity is >0 (indicating that LFQ is erroneously 0) ’toNA’: replace by NA “impute”: replace by lowest LFQ value >0 (simulating ’noise’)

... Additional parameters passed on to read.delim()

colname Name of the column (e.g. ’contaminants’) in the mq.data table
valid_entries Vector of values to be replaced (must contain all values expected in the column – fails otherwise)
replacements Vector of values inserted with the same length as valid_entries.

**Details**

Since MaxQuant changes capitalization and sometimes even column names, it seemed convenient to have a function which just reads a txt file and returns unified column names, irrespective of the MQ version. So, it unifies access to columns (e.g. by using lower case for ALL columns) and ensures columns are identically named across MQ versions:

<table>
<thead>
<tr>
<th>alternative term</th>
<th>new term</th>
</tr>
</thead>
<tbody>
<tr>
<td>protease</td>
<td>enzyme</td>
</tr>
<tr>
<td>protein.descriptions</td>
<td>fasta.headers</td>
</tr>
<tr>
<td>potential.contaminant</td>
<td>contaminant</td>
</tr>
<tr>
<td>mass.deviations</td>
<td>mass.deviations..da.</td>
</tr>
<tr>
<td>basepeak.intensity</td>
<td>base.peak.intensity</td>
</tr>
</tbody>
</table>

We also correct ’reporter.intensity.*’ naming issues to MQ 1.6 convention, when ’reporter.intensity.not.corrected’ is present. MQ 1.5 uses: reporter.intensity.X and reporter.intensity.not.corrected.X MQ 1.6 uses: reporter.intensity.X and reporter.intensity.corrected.X

Note: you must find a regex which matches both versions, or explicitly add both terms if you are requesting only a subset of columns!

Fixes for msmsScans.txt: negative Scan Event Numbers in msmsScans.txt are reconstructed by using other columns

Automatically detects UTF8-BOM encoding and deals with it (since MQ2.4).

Example of usage:

```r
mq = MQDataReader$new()
d_evd = mq$readMQ("evidence.txt", type="ev", filter="R", col_subset=c("proteins", "Retention.Length"))
```

If the file is empty, this function shows a warning and returns NULL. If the file is present but cannot be read, the program will stop.

Wrapper to read a MQ txt file (e.g. proteinGroups.txt).
Value

A data.frame of the respective file

Replaces values in the mq.data member with (binary) values. Most MQ tables contain columns like 'contaminants' or 'reverse', whose values are either empty strings or "+", which is inconvenient and can be much better represented as TRUE/FALSE. The params valid_entries and replacements contain the matched pairs, which determine what is replaced with what.

Returns TRUE if successful.

Methods

getInvalidLines() Detect broken lines (e.g. due to Excel import+export)

When editing a MQ txt file in Microsoft Excel, saving the file can cause it to be corrupted, since Excel has a single cell content limit of 32k characters (see http://office.microsoft.com/en-001/excel-help/excel-specifications-and-limits-HP010342495.aspx) while MQ can easily reach 60k (e.g. in oxidation sites column). Thus, affected cells will trigger a line break, effectively splitting one line into two (or more).

If the table has an 'id' column, we can simply check the numbers are consecutive. If no 'id' column is available, we detect line-breaks by counting the number of NA's per row and finding outliers. The line break then must be in this line (plus the preceding or following one). Depending on where the break happened we can also detect both lines right away (if both have more NA's than expected).

Currently, we have no good strategy to fix the problem since columns are not aligned any longer, which leads to columns not having the class (e.g. numeric) they should have. (thus one would need to un-do the linebreak and read the whole file again)

[Solution to the problem: try LibreOffice 4.0.x or above – seems not to have this limitation]

@return Returns a vector of indices of broken (i.e. invalid) lines
Methods

RTUnitCorrection(dt) Convert all RT columns from seconds (OpenMS default) to minutes (MaxQuant default)

gEvidence() Basically the PSM table and additionally columns named 'raw.file' and 'fc.raw.file'.

gGetMSSScans(identified_only = FALSE) Basically the PSM table (partially renamed columns) and additionally two columns 'raw.file' and 'fc.raw.file'. If identified_only is TRUE, only MS2 scans which were identified (i.e. a PSM) are returned – this is equivalent to msms.txt in MaxQuant.

gGetParameters() Converts internal mzTab metadata section to a two column key-value data.frame similar to MaxQuants parameters.txt.

gGetProteins() Basically the PRT table ...

gGetSummary() Converts internal mzTab metadata section to a two data.frame with columns 'fc.raw.file', 'ms.ms.identified....' similar to MaxQuants summary.txt.
enameColumns(dt, namelist) Renames all columns and throws a warning if a column does not exist in the data

Description

pastes with newline as separator

Usage

pastes(...)

Arguments

... Arguments forwarded to paste()

Value

return value of paste()

Examples

pastes("newline","separated")
## --> "newline
separated"
**pastet**

*Description*

paste with tab as separator

*Usage*

```r
pastet(...)```

*Arguments*

...  
Arguments forwarded to `paste()`

*Value*

return value of `paste()`

*Examples*

```r
pastet("tab","separated")
## --> "tab\tseparated"
```

---

**peakSegmentation**

*Description*

Determine fraction of evidence which causes segmentation, i.e. sibling peaks at different RTs confirmed either by genuine or transferred MS/MS.

*Usage*

```r
peakSegmentation(df_evd_all)```

*Arguments*

```r
df_evd_all    A data.frame of evidences containing the above columns```

Sometimes, MQ splits a feature into 2 or more if the chromatographic conditions are not optimal and there is a drop in RT intensity. If both features contain successful MS/MS scans, we will find the same peptide twice (with slightly different RT) in the same charge state. This constitutes a natively split peak and is rare (95
Details

If Match-between-runs is used and the RT alignment is not perfect, then a peptide might be inferred at a wrong RT position, even though this Raw file already contains MS/MS evidence of this peptide. Usually the number of peak duplicates rises drastically (e.g. only 75 In most cases, the RT is too far off to be a split peak. It’s rather a lucky hit with accidentally the same mass-to-charge, and thus the intensity is random. To find by how much these peak pairs differ in RT, use idTransferCheck() and inMatchWindow().

Required columns are 'is.transferred', 'fc.raw.file', 'modified.sequence', 'charge', 'type'.

Note that this function must be given MS/MS identifications of type "MULTI-MSMS" and "MSMS-MATCH". It will stop() otherwise.

Value

A data.frame with one row per Raw file and three columns: 1) 2) 3)

peakWidthOverTime

Discretize RT peak widths by averaging values per time bin.

Description

Should be applied for each Raw file individually.

Usage

peakWidthOverTime(data, RT_bin_width = 2)

Arguments

data Data.frame with columns 'retention.time' and 'retention.length'

RT_bin_width Bin size in minutes

Details

Returns a data.frame, where 'bin' gives the index of each bin, 'RT' is the middle of each bin and 'peakWidth' is the averaged peak width per bin.

Value

Data.frame with columns 'bin', 'RT', 'peakWidth'

Examples

```r
data = data.frame(retention.time = seq(30, 200, by=0.001))  ## one MS/MS per 0.1 sec
data$retention.length = seq(0.3, 0.6, length.out = nrow(data)) + rnorm(nrow(data), 0, 0.1)
d = peakWidthOverTime(data)
plot(d$RT, d$peakWidth)
```
plotTable

Plot a table with row names and title

Description

Restriction: currently, the footer will be cropped at the table width.

Usage

plotTable(
  data,
  title = "", 
  footer = "", 
  col_names = colnames(data), 
  fill = c("grey90", "grey70"), 
  col = "black", 
  just = "centre"
)

Arguments

data A data.frame with columns as described above

title Table title

footer Footer text

col_names Column names for Table

fill Fill pattern (by row)

col Text color (by column)

just (ignored)

Value

gTree object with class 'PTXQC_table'

Examples

data = data.frame(raw.file = letters[1:4],
  id.rate = 3:6)

plotTable(data,
  title = "Bad files",
  footer = "bottom",
  col_names = c("first col", "second col"),
  col=c("red", "green"))
plotTableRaw | Colored table plot.

Description

Usage

plotTableRaw(data, colours = "black", fill = NA, just = "centre")

Arguments

data | Table as Data.frame
colours | Single or set of colours (col-wise)
fill | Cell fill (row-wise)
just | (ignored)

Value

gTable

plot_CalibratedMSErr | Plot bargraph of uncalibrated mass errors for each Raw file.

Description

Boxes are optionally colored to indicate that a MQ bug was detected or if PTXQC detected a too narrow search window.

Usage

plot_CalibratedMSErr(
  data,
  MQBug_raw_files,
  stats,
  y_lim,
  extra_limit = NA,
  title_sub = ""
)
**plot_Charge**

**Arguments**

- **data**
  A data.frame with columns 'fc.raw.file', 'mass.error..ppm.'

- **MQBug_raw_files**
  List of Raw files with invalid calibration values

- **stats**
  A data.frame with columns 'fc.raw.file', 'outOfCal'

- **y_lim**
  Range of y-axis

- **extra_limit**
  Position where a v-line is plotted (for visual guidance)

- **title_sub**
  Subtitle

**Value**

GGplot object

**Examples**

```r
n = c(150, 1000, 1000, 1000)
data = data.frame(fc.raw.file = repEach(letters[4:1], n),
  mass.error..ppm. = c(rnorm(n[1], 1, 2.4),
                        rnorm(n[2], 0.5, 0.5),
                        rnorm(n[3], 0.1, 0.7),
                        rnorm(n[4], 0.3, 0.8)))
stats = data.frame(fc.raw.file = letters[4:1],
  sd = c(2.4, 0.5, 0.7, 0.8),
  outOfCal = c(TRUE, FALSE, FALSE, FALSE))
plot_CalibratedMSErr(data, MQBug_raw_files = letters[1], stats, y_lim = c(-20,20), 15, "subtitle")
```

---

**plot_Charge**

*The plots shows the charge distribution per Raw file. The output of 'mosaicize()' can be used directly.*

**Description**

The input is a data.frame with columns 'Var1' - name of the Raw file 'Var2' - charge (used as fill color) 'Var1_center' - contains X-position of the Raw file 'Var2_height' - relative frequency of the charge 'Margin_var1' - where each row represents one peptide sequence.

**Usage**

```r
plot_Charge(d_charge)
```

**Arguments**

- **d_charge**
  A data.frame with columns as described above
plot_ContEVD

Value

GGplot object

Examples

data = data.frame(raw.file = c(rep('file A', 100), rep('file B', 40)),
                 data = c(rep(2, 60), rep(3, 30), rep(4, 10),
                          rep(2, 30), rep(3, 7), rep(4, 3)))
plot_Charge(mosaicize(data))

Description

Plot contaminants from evidence.txt, broken down into top5-proteins.

Usage

plot_ContEVD(data, top5)

Arguments

data A data.frame with columns 'fc.raw.file', 'contaminant', 'pname', 'intensity'
top5 Name of the Top-5 Proteins (by relative intensity or whatever seems relevant)

Value

GGplot object

Examples

data = data.frame(intensity = 1:12,
                   pname = rep(letters[1:3], 4),
                   fc.raw.file = rep(paste("f", 1:4), each=3),
                   contaminant = TRUE)
## providing more proteins than present... d,e will be ignored
plot_ContEVD(data, top5 = letters[1:5])
## classify 'c' as 'other'
plot_ContEVD(data, top5 = letters[1:2])
plot_ContsPG  

Plot contaminants from proteinGroups.txt

Description

Plot contaminants from proteinGroups.txt

Usage

plot_ContsPG(data)

Arguments

data A data.frame with columns 'group', 'cont_pc', 'logAbdClass'

Value

GGplot object

Examples

data = data.frame('group' = letters[1:10], 'cont_pc' = 2:11, 'logAbdClass' = c("low","high"))
plot_ContsPG(data)

plot_ContUser  

Plot user-defined contaminants from evidence.txt

Description

Kolmogorov-Smirnoff p-values are plotted on top of each group. High p-values indicate that Andromeda scores for contaminant peptides are equal or higher compared to sample peptide scores, i.e. the probability that sample peptides scores are NOT greater than contaminant peptide scores.

Usage

plot_ContUser(data, name_contaminant, extra_limit, subtitle = NULL)

Arguments

data A data.frame with columns 'fc.raw.file', 'variable', 'value'
name_contaminant Name of the contaminant shown in title
extra_limit Position where a h-line is plotted (for visual guidance)
subtitle Optional subtitle for plot
plot_ContUserScore

Value

GGplot object

Examples

data = data.frame(fc.raw.file = letters[1:3],
  variable = c(rep("spectralCount", 3),
    rep("intensity", 3),
    rep("above.thresh", 3),
    rep("score_KS", 3)),
  value = c(10, 20, 15, 9, 21, 14, 0, 1, 1, 0.3, 0.01, 0.04))
plot_ContUser(data, "myco", 5, "subtitle")

Description

The data is expected to be an ECDF already, x being the Andromeda score, y being the cumulative probability. The Score is the probability of a Kolm.-Smirnoff test that the contaminant scores are larger (i.e. large p-values indicate true contamination). You will only see this plot if the but high-scoring contaminant peptides, which would erroneously give you a large p-value and make you believe your sample is contaminated although that’s not the case.

Usage

plot_ContUserScore(data, raw.file, score)

Arguments

data A data.frame with columns 'x', 'y', 'condition'
raw.file Name of Raw file for which the data is displayed (will become part of the plot title)
score Score of how distinct the distributions are (will become part of the title)

Value

GGplot object
Examples

```r
data = data.frame(x = 10:60,
                  y = c(seq(0, 1, length=51), seq(0.1, 1, length=51)),
                  condition = rep(c("sample", "contaminant"), each=51))
plot_ContUserScore(data, 'test file', 0.96)
```

plot_CountData  
**Plot Protein groups per Raw file**

Description

The input is a data.frame with protein/peptide counts, where 'category' designates the origin of information (genuine ID, transferred ID, or both).

Usage

```r
plot_CountData(data, y_max, thresh_line, title)
```

Arguments

- `data`: A data.frame with columns 'fc.raw.file', 'counts', 'category'
- `y_max`: Plot limit of y-axis
- `thresh_line`: Position of a threshold line, indicating the usual target value
- `title`: Main title, and optional subtitle (if vector of length 2 is provided)

Value

GGplot object

Examples

```r
data = data.frame(fc.raw.file = rep(c("file A", "file B"), each=3),
                  counts = c(3674, 593, 1120, 2300, 400, 600),
                  category = c("genuine", "genuine+transferred", "transferred"))
plot_CountData(data, 6000, 4000, c("EVD: Protein Groups count", "gain: 23%"))
```
plot_DataOverRT

Plot some count data over time for each Raw file.

Description

The input is a data.frame with columns 'RT' - RT in seconds, representing one bin 'counts' - number of counts at this bin 'fc.raw.file' - name of the Raw file where each row represents one bin in RT.

Usage

plot_DataOverRT(
  data,
  title,
  y_lab,
  x_lim = range(data$RT),
  y_max = max(data$counts)
)

Arguments

data A data.frame with columns as described above
title The plot title
y_lab Label of y-axis
x_lim Limits of the x-axis (2-tuple)
y_max Maximum of the y-axis (single value)

Details

At most nine(!) Raw files can be plotted. If more are given, an error is thrown.

Value

GGplot object

Examples

data = data.frame(fc.raw.file = rep(paste('file', letters[1:3]), each=30),
  RT = seq(20, 120, length.out = 30),
  counts = c(rnorm(30, 400, 20), rnorm(30, 250, 15), rnorm(30, 50, 15)))
plot_DataOverRT(data, "some title", "count data")
plot_IDRate

Plot percent of identified MS/MS for each Raw file.

Description
Useful for a first overall impression of the data.

Usage
plot_IDRate(data, id_rate_bad, id_rate_great, label_ID)

Arguments
- data: A dataframe with columns as described above
- id_rate_bad: Number below which the ID rate is considered bad
- id_rate_great: Number above which the ID rate is considered great
- label_ID: Named vector with colors for the categories given in data$cat

Details
The input is a dataframe with columns 'fc.raw.file' - name of the Raw file 'ms.ms.identified....' - fraction of identified MS/MS spectra in percent 'cat' - identification category as arbitrary string where each row represents one Raw file.

Value
GGplot object

Examples

id_rate_bad = 20; id_rate_great = 35;
label_ID = c("bad (<20%)" = "red", "ok (...)" = "blue", "great (>35%)" = "green")
data = data.frame(fc.raw.file = paste('file', letters[1:3]),
               ms.ms.identified.... = rnorm(3, 25, 15))
data$cat = factor(cut(data$ms.ms.identified....,
                      breaks=c(-1, id_rate_bad, id_rate_great, 100),
                      labels=names(label_ID)))
plot_IDRate(data, id_rate_bad, id_rate_great, label_ID)
plot_IDsOverRT

Plot IDs over time for each Raw file.

Description

Uses plot_DataOverRT() internally.

Usage

plot_IDsOverRT(data, x_lim = range(data$RT), y_max = max(data$counts))

Arguments

- data: A data.frame with columns as described above
- x_lim: Limits of the x-axis (2-tuple)
- y_max: Maximum of the y-axis (single value)

Value

A GGplot object

Examples

data = data.frame(fc.raw.file = rep(paste('file', letters[1:3]), each=30),
                 RT = seq(20, 120, length.out = 30),
                 counts = c(rnorm(30, 400, 20), rnorm(30, 250, 15), rnorm(30, 50, 15)))
plot_IDsOverRT(data)

plot_IonInjectionTimeOverRT

Plot line graph of TopN over Retention time.

Description

Number of Raw files must be 6 at most. Function will stop otherwise.

Usage

plot_IonInjectionTimeOverRT(data, stats, extra_limit)

Arguments

- data: A data.frame with columns 'fc.raw.file', 'rRT', 'medIIT'
- stats: A data.frame with columns 'fc.raw.file', 'mean'
- extra_limit: Visual guidance line (maximum acceptable IIT)
**plot_MBRAlign**

**Value**

GGplot object

**Examples**

```r
data = data.frame(fc.raw.file = rep(c("d","a","x"), each=100),
                  rRT = seq(20, 120, length.out = 100),
                  medIIT = c(round(runif(100, min=3, max=5)),
                              round(runif(100, min=5, max=8)),
                              round(runif(100, min=1, max=3)))

stats = data.frame(fc.raw.file = c("d","a","x"),
                   mean = c(4, 6.5, 2))

plot_IonInjectionTimeOverRT(data, stats, 10)
```

---

**plot_MBRAlign**  
*Plot MaxQuant Match-between-runs alignment performance.*

**Description**

The plots shows the correction function applied by MaxQuant, and the residual RT (ideally 0) of each peptide to its reference. Uncalibrated peptides are shown in red, calibrated ones in green. The MaxQuant RT correction which was applied prior is shown in blue. The range of this function can give hints if the allowed RT search window (20min by default) is sufficient or if MaxQuant should be re-run with more tolerant settings.

**Usage**

`plot_MBRAlign(data, y_lim, title_sub, match_tol)`

**Arguments**

- `data`  
  A data.frame with columns as described above
- `y_lim`  
  Plot range of y-axis
- `title_sub`  
  Subtitle
- `match_tol`  
  Maximal residual RT delta to reference (usually ~1 min)

**Details**

The input is a data.frame with columns 'calibrated.retention.time' - resulting (hopefully) calibrated RT after MQ-recal (the X-axis of the plot) 'retention.time.calibration' - delta applied by MaxQuant 'rtdiff' - remaining RT diff to reference peptide of the same sequence 'RTdiff_in' - is the feature aligned (within 'match_tol')? 'fc.raw.file_ext' - raw file where each row represents one peptide whose RT was corrected by MaxQuant.
plot_MBRgain

Plot MaxQuant Match-between-runs id transfer performance.

Description
The plots shows the different categories of peak classes

Usage
plot_MBRgain(data, title_sub = "")

Arguments
- data: A data.frame with columns as described above
- title_sub: Subtitle text

Details
The input is a data.frame with columns 'fc.raw.file' - raw file name 'single' - fraction of peptides with are represent only once 'multi.inRT' - fraction of peptides with are represent multiple times, but within a certain RT peak width 'multi.outRT' - fraction of peptides with are represent multiple times, with large RT distance 'sample' - raw file where each row represents one peptide sequence.

Value
GGplot object

Examples
```
data = data.frame(fc.raw.file = paste("file", letters[1:4]),
                   abs = c(5461, 5312, 3618, 502),
                   pc = c(34, 32, 22, 2))
plot_MBRgain(data, "MBR gain: 18%")
```
plot_MBRIDtransfer

Plot MaxQuant Match-between-runs id transfer performance.

Description
The plots shows the different categories of peak classes

Usage
plot_MBRIDtransfer(data)

Arguments
data A data.frame with columns as described above

Details
The input is a data.frame with columns 'fc.raw.file' - raw file name 'single' - fraction of peptides with are represent only once 'multi.inRT' - fraction of peptides with are represent multiple times, but within a certain RT peak width 'multi.outRT' - fraction of peptides with are represent multiple times, with large RT distance 'sample' - raw file where each row represents one peptide sequence.

Value
GGplot object

Examples
data = data.frame(fc.raw.file = rep(c("file A", "file B"), each = 3),
  single = c(0.9853628, 0.8323160, 0.9438375,
             0.9825538, 0.8003763, 0.9329961),
  multi.inRT = c(0.002927445, 0.055101018, 0.017593087,
                0.005636457, 0.099640044, 0.031870056),
  multi.outRT = c(0.01170978, 0.11258294, 0.03856946,
                 0.01180972, 0.09998363, 0.03513386),
  sample = rep(c("genuine", "transferred", "all"), 2))
plot_MBRIDtransfer(data)
plot_MissedCleavages  
*Plot bargraph of missed cleavages.*

**Description**
Per Raw file, an arbitrary number of missed cleavage classes (one per column) can be given. The total fraction of 3D-peaks must sum to 1 (=100). Columns are ordered by name.

**Usage**
```r
plot_MissedCleavages(data, title_sub = "")
```

**Arguments**
- `data`: A data.frame with columns `fc.raw.file`, `...` (missed cleavage classes)
- `title_sub`: Plot’s subtitle

**Details**
A visual threshold line is drawn at 75

**Value**
GGplot object

**Examples**
```r
data = data.frame(fc.raw.file = letters[1:5],
                  MC0 = c(0.8, 0.5, 0.85, 0.2, 0.9),
                  MC1 = c(0.1, 0.4, 0.05, 0.7, 0.0),
                  "MS2+" = c(0.1, 0.1, 0.1, 0.1, 0.1),
                  check.names = FALSE)
plot_MissedCleavages(data, "contaminant inclusion unknown")
```

plot_MS2Decal  
*Plot bargraph of oversampled 3D-peaks.*

**Description**
Per Raw file, at most three n’s must be given, i.e. the fraction of 3D-peaks for n=1, n=2 and n=3 (or more). The fractions must sum to 1 (=100)

**Usage**
```r
plot_MS2Decal(data)
```
Arguments

data A data.frame with columns 'file', 'msErr', 'type'

Value

GGplot object

Examples

```r
n = c(100, 130, 50)
data = data.frame(file = repEach(paste(letters[1:3], "LTQ [Da]"), n),
               msErr = c(rnorm(n[1], 0.5), rnorm(n[2], 0.0), rnorm(n[3], -0.5)),
               type = c("forward", "decoy"[(1+runif(sum(n))>0.95)]))
plot_MS2Decal(data)
```

---

**Description**

Per Raw file, at most three n’s must be given, i.e. the fraction of 3D-peaks for n=1, n=2 and n=3(or more). The fractions must sum to 1 (=100)

**Usage**

```r
plot_MS2Oversampling(data)
```

**Arguments**

data A data.frame with columns 'fc.raw.file', 'n', 'fraction'

**Value**

GGplot object

**Examples**

```r
data = data.frame(fc.raw.file = rep(letters[1:3], each=3),
n = 1:3,
           fraction = c(0.8, 0.1, 0.1, 0.6, 0.3, 0.1, 0.7, 0.25, 0.05))
plot_MS2Oversampling(data)
```
Description
The input is a data.frame, as obtained from modsToTableByRaw().

Usage
plot_peptideMods(tbl, y_max = NA, show_missing_modification_levels = TRUE)

Arguments
tbl A data.frame with 'fc.raw.file', 'modification_names' (can be a factor), and 'Freq' (0-100)
y_max The upper limit of the y-axis's (==Freq); useful for multiple plots with identical limits; if 'NA' the limit is computed from the given 'tbl'
show_missing_modification_levels If 'tbl$modification_names' is a factor and has more (but missing) levels than actually used, should missing values be dropped or assumed as '0' frequency?

Value
GGplot object

Examples

data = data.frame(fc.raw.file = rep(c("file A", "file B"), each=3), modifications = c("Oxidation (M)", "Unmodified", "Oxidation (M), Acetyl (Protein N-term)", "2 Oxidation (M)", "Unmodified", "Unmodified"))

tbl = modsToTableByRaw(data)
plot_peptideMods(tbl, show_missing_modification_levels = TRUE)
Description

The 'x' values are expected to be log2() transformed already.

Usage

plot_RatiosPG(df_ratios, d_range, main_title, main_col, legend_title)

Arguments

df_ratios A data.frame with columns 'x', 'y', 'col', 'ltype'
d_range X-axis range of plot
main_title Plot title
main_col Color of title
legend_title Legend text

Value

GGplot object

Examples

```r
x1 = seq(-3, 3, by = 0.1)
y1 = dnorm(x1)
x2 = seq(-5, 1, by = 0.1)
y2 = dnorm(x2, mean = -1)
data = data.frame( x = c(x1,x2),
y = c(y1,y2),
col = c(rep("ok", length(x1)), rep("shifted", length(x2))),
ltype = c(rep("solid", length(x1)), rep("dotted", length(x2))))
plot_RatiosPG(data, range(data$x), "Ratio plot", "red", "group")
```
**plot_RTPeakWidth**  
*Plot RT peak width over time*

**Description**

The input is a data.frame with already averaged counts over binned RT-slices.

**Usage**

```r
plot_RTPeakWidth(data, x_lim, y_lim)
```

**Arguments**

- `data`: A data.frame with columns 'fc.raw.file', 'RT', 'peakWidth'
- `x_lim`: Plot range of x-axis
- `y_lim`: Plot range of y-axis

**Value**

GGplot object

**Examples**

```r
data = data.frame(fc.raw.file = rep(c("file A", "file B", "file C"), each=81),
                RT = c(20:100),
                peakWidth = c(rnorm(81, mean=20), rnorm(81, mean=10), rnorm(81, mean=30)))
plot_RTPeakWidth(data, c(10, 100), c(0, 40))
```

---

**plot_ScanIDRate**  
*Plot line graph of TopN over Retention time.*

**Description**

Number of Raw files must be 6 at most. Function will stop otherwise.

**Usage**

```r
plot_ScanIDRate(data)
```

**Arguments**

- `data`: A data.frame with columns 'fc.raw.file', 'scan.event.number', 'ratio', 'count'
plot_TIC

Value

GGplot object

Examples

data = data.frame(fc.raw.file = factor(rep(c("d","a","x"), each=10), levels = c("d","a","x")),
    scan.event.number = 1:10,
    ratio = seq(40, 20, length.out=10),
    count = seq(400, 200, length.out=10))
plot_ScanIDRate(data)

Description

The input is a data.frame with already averaged counts over binned RT-slices.

Usage

plot_TIC(data, x_lim, y_lim)

Arguments

data A data.frame with columns 'fc.raw.file', 'RT', 'intensity'
x_lim Plot range of x-axis
y_lim Plot range of y-axis

Value

GGplot object

Examples

data = data.frame(fc.raw.file = rep(c("file A", "file B", "file C"), each=81),
    RT = c(20:100),
    intensity = c(rnorm(81, mean=20), rnorm(81, mean=10), rnorm(81, mean=30)))
plot_TIC(data, c(10, 100), c(0, 40))
**plot_TopN**

*Plot line graph of TopN over Retention time.*

**Description**

Number of Raw files must be 6 at most. Function will stop otherwise.

**Usage**

```r
plot_TopN(data)
```

**Arguments**

- `data` A data.frame with columns `fc.raw.file`, `scan.event.number`, `n`

**Value**

GGplot object

**Examples**

```r
data = data.frame(fc.raw.file = rep(c("d","a","x"), each=10),
                  scan.event.number = 1:10,
                  n = 11:20)
plot_TopN(data)
```

---

**plot_TopNoverRT**

*Plot line graph of TopN over Retention time.*

**Description**

Number of Raw files must be 6 at most. Function will stop otherwise.

**Usage**

```r
plot_TopNoverRT(data)
```

**Arguments**

- `data` A data.frame with columns `fc.raw.file`, `rRT`, `topN`

**Value**

GGplot object
Examples

data = data.frame(fc.raw.file = rep(letters[1:3], each=100),
                 rRT = seq(20, 120, length.out = 100),
                 topN = c(round(runif(100, min=3, max=5)),
                          round(runif(100, min=5, max=8)),
                          round(runif(100, min=1, max=3)))
)
plot_TopNoverRT(data)

**plot_UncalibratedMSErr**

*A boxplot of uncalibrated mass errors for each Raw file.*

Description

Boxes are optionally colored to indicate that a MQ bug was detected or if PTXQC detected a too narrow search window.

Usage

```r
plot_UncalibratedMSErr(
  data,  
  MQBug_raw_files,  
  stats,  
  y_lim,  
  extra_limit,  
  title_sub
)
```

Arguments

data A data.frame with columns 'fc.raw.file', 'uncalibrated.mass.error..ppm.'
MQBug_raw_files List of Raw files with invalid calibration values
stats A data.frame with columns 'fc.raw.file', 'sd', 'outOfCal'
y_lim Range of y-axis
extra_limit Position where a v-line is plotted (for visual guidance)
title_sub Subtitle

Value

GGplot object
Examples

```r
n = c(150, 1000, 1000, 1000)
data = data.frame(fc.raw.file = repEach(letters[4:1], n),
                  uncalibrated.mass.error..ppm. = c(rnorm(n[1], 13, 2.4),
                                              rnorm(n[2], 1, 0.5),
                                              rnorm(n[3], 3, 0.7),
                                              rnorm(n[4], 4.5, 0.8)))

stats = data.frame(fc.raw.file = letters[4:1],
                    sd_uncal = c(2.4, 0.5, 0.7, 0.8),
                    outOfCal = c(TRUE, FALSE, FALSE, FALSE))

plot_UncalibratedMSErr(data, MQBug_raw_files = letters[1],
                        stats, y_lim = c(-20,20), 15, "subtitle")
```

Description

`pointsPutX` *Distribute a set of points with fixed y-values on a stretch of the x-axis.*

Usage

```r
pointsPutX(x_range, x_section, y, col = NA)
```

Arguments

- `x_range` [min,max] valid range of x-values
- `x_section` [min,max] fraction in which to distribute the values (in [0,1] for min,max, e.g. c(0.03,0.08) for 3-8%)  
- `y` Y-values
- `col` Colour of the points (used as argument to aes(colour=))

Value

`ggplot` object with new geom_point
print.PTXQC_table  

**Description**

helper S3 class, enabling print(some-plot_Table-object)

**Usage**

```r
## S3 method for class 'PTXQC_table'
print(x, ...)
```

**Arguments**

- `x`  
  Some Grid object to plot

- `...`  
  Further arguments (not used, but required for consistency with other print methods)

---

printWithFooter  

**Description**

Augment a ggplot with footer text

**Usage**

```r
printWithFooter(gg_obj, bottom_left = NULL, bottom_right = NULL)
```

**Arguments**

- `gg_obj`  
  ggplot2 object to be printed

- `bottom_left`  
  Footer text for bottom left side

- `bottom_right`  
  Footer text for bottom right side

**Value**

-
QCMetaFilenames

 Define a Singleton class which holds the full raw filenames (+path) and their PSI-MS CV terms for usage in the mzQC metadata

Description

Define a Singleton class which holds the full raw filenames (+path) and their PSI-MS CV terms for usage in the mzQC metadata

Super class

R6P::Singleton -> QCMetaFilenames

Public fields

data Stores the data of the singleton. Set the data once before using the singleton all over the place

Methods

Public methods:

• QCMetaFilenames$clone()

Method clone(): The objects of this class are cloneable with this method.

Usage:
QCMetaFilenames$clone(deep = FALSE)

Arguments:

• deep Whether to make a deep clone.

qcMetric-class

Class which can compute plots and generate mzQC output (usually for a single metric).

Description

Reference class which is instanciated with a metric description and a worker function (at initialization time, i.e. in the package) and can produce plots and mzQC values (at runtime, when data is provided) using setdata().
qcMetric-class

Fields

helpText  Description (lengthy) of the metric and plot elements

workerFcn  Function which generates a result (usually plots). Data is provided using setData().

plots  List of plots (after setData() was called)

qcScores  Data.frame of scores from a qcMetric (computed within workerFcn())

mzQC  An named list of mzQC MzQCqualityMetric’s (named by their fc.raw.file for runQuality or concatenated fc.raw.files for setQualities (e.g. “file 1;file4“)) (valid after setData() was called)

qcCat  QC category (LC, MS, or prep)

qcName  Name of the qcScore in the heatmap

orderNr  Column index during heatmap generation and for the general order of plots

Examples

```
require(ggplot2)
dd = data.frame(x=1:10, y=11:20)
a = qcMetric$new(helpText="small help text",
  ## arbitrary arguments, matched during setData()
  workerFcn=function(.self, data, gtit)
  {
    ## usually some code here to produce ggplots
    pl = lapply(1:2, function(xx) {
      ggplot(data) +
      geom_point(aes(x=x*xx,y=y)) +
      ggtitle(gtit)
    })
    return(list(plots = pl))
  },
  qcCat="LC",
  qcName="MS/MS Peak shape",
  orderNr = 30)
  ## test some output
a$setData(dd, "my title")
a$plots  ## the raw plots
a$getPlots(TRUE)  ## same as above
a$getPlots(FALSE)  ## plots without title
a$getTitles()  ## get the titles of the all plots
a$helpText
a$ qcName
```
**qcMetric_MSMSScans_TopNoverRT-class**

*Metric for msmsscans.txt, showing TopN over RT.*

**Description**

Metric for msmsscans.txt, showing TopN over RT.

**qualBestKS**

*From a list of vectors, compute all vs. all Kolmogorov-Smirnoff distance statistics (D)*

**Description**

... and report the row of the matrix which has maximum sum (i.e the best "reference" distribution). The returned data.frame has as many rows as distributions given and two columns. The first column 'name' gives the name of the list element, the second column 'ks_best' gives '1-statistic' of the Kolmogorov-Smirnoff test to the "reference" distribution (which was picked by maximising the sum of 'ks_best'). Thus, the row with a 'ks_best' of 1 is the reference distribution.

**Usage**

qualBestKS(x)

**Arguments**

x

List of vectors, where each vector holds a distribution

**Value**

A data.frame with ks-test values of the "reference" to all other distributions (see Details)

**qualCentered**

*Quality metric for 'centeredness' of a distribution around zero.*

**Description**

Ranges between 0 (worst score) and 1 (best score). A median of zero gives the best score of 1. The closer the median is to the most extreme value of the distribution, the smaller the score (until reaching 0). Can be used for calibrated mass errors, as a measure of how well they are centered around 0. E.g. if the median is 0.1, while the range is [-0.5,0.5], the score will be 0.8 (punishing the 20 If the range of data is asymmetric, e.g. [-1.5,-0.5] and does not include zero, the score cannot reach 1, since the median can never be zero.
qualCenteredRef

Usage

qualCentered(x)

Arguments

x Numeric values (e.g. ppm errors)

Value

Value between [0, 1]

Description

Ranges between 0 (worst score) and 1 (best score). The best score is achieved when the median of 'x' is close to the center of the interval [-tol, tol]. If median of 'x' is close to the border (on either side), the score decreases linearly to zero. Can be used for uncalibrated mass errors, as a measure of how well they are centered around 0.

Usage

qualCenteredRef(x, tol)

Arguments

x Vector of values (hopefully in interval [-tol, tol])
tol Border of interval (must be positive)

Details

NA's are removed for all computations.

Value

Value between [0, 1]
qualGaussDev

*Compute probability of Gaussian (mu=m, sd=s) at a position 0, with reference to the max obtainable probability of that Gaussian at its center.*

**Description**

Measure for centeredness around 0. Highest score is 1, worst score is 0.

**Usage**

```r
qualGaussDev(mu, sd)
```

**Arguments**

- `mu` Center of Gaussian
- `sd` SD of Gaussian

**Value**

quality, ranging from 0 (bad agreement) to 1 (perfect, i.e. centered at 0)

---

qualHighest

*Score an empirical density distribution of values, where the best possible distribution is right-skewed.*

**Description**

The score is computed according to

**Usage**

```r
qualHighest(x, N)
```

**Arguments**

- `x` Vector of numeric values (e.g. height of histogram bins)
- `N` Length of x (just a precaution currently)

**Details**

```r
q = ((N-1) - sum_i( ((N-i-1)*x_i)) / (N-1)
```

Scores range from 0 (worst), to 1 (best). E.g. `c(0,0,0,16)` would yield a score of 1. `c(16,0,0,0,0)` gives a score of 0.
**Value**

Quality score in the range of [0, 1]

**Examples**

```r
qualHighest(c(0, 0, 0, 16), 4)  ## 1
qualHighest(c(16, 0, 0, 0), 4)  ## 0
qualHighest(c(1, 1, 1, 1), 4)   ## 0.5
qualHighest(c(0, 16, 0, 0), 4)  ## 1/3
```

**qualLinThresh**

*Quality metric with linear response to input, reaching the maximum score at the given threshold.*

**Description**

Ranges between 0 (worst score) and 1 (best score). Useful for performance measures where reaching a certain reference threshold 't' will be enough to reach 100%. The input range from [0, t] is scored from 0-100%.

**Usage**

```r
qualLinThresh(x, t = 1)
```

**Arguments**

- `x`: Numeric value(s) between [0, inf]
- `t`: Threshold value, which indicates 100%

**Value**

Value between [0, 1]

**qualMedianDist**

*Quality metric which measures the absolute distance from median.*

**Description**

Ranges between 0 (worst score) and 1 (best score). Input must be between [0,1]. Deviations from the median of the sample represent the score for each sample point.

**Usage**

```r
qualMedianDist(x)
```
Arguments

x
A vector numeric values between [0, 1]

Value

A vector of the same size as x, with quality values between [0, 1]

qualUniform  Compute deviation from uniform distribution

Description

The score ranges between 0 (worst score) and 1 (best score). Input 'x' is a vector of counts (or probabilities) for equally spaced bins in a histogram. A uniform distribution (e.g. c(3,3,3) will get a score of 1. The worst possible case (e.g. c(4,0,0)), will get a score of 0, and a linear increasing function (e.g. c(1,2,3)) will get something in between (0.585 here)

Usage

qualUniform(x, weight = vector())

Arguments

x
Vector of numeric intensity/count values (e.g. ID’s per RT bin); bins are assumed to have equal widths

weight
Vector of weights for values in ‘x’ (same length as ‘x’).

Details

In addition, bin values can be weighted (e.g. by their confidence). The total sum of weights is normalized to 1 internally.

The distance function used is the square root of the absolute difference between a uniform distribution and the input 'x' (summed for each element of 'x'). This distance is normalized to the worst possible input (e.g. one bin with 100

Value

Value between [0, 1]

Examples

stopifnot(qualUniform(c(3,3,3))==1)
stopifnot(qualUniform(c(4,0,0))==0)

## how ‘uniform’ is a vector where only a single index has weight?-- answer: very
stopifnot(qualUniform(c(4,0,0), c(1,0,0))==1)
stoiifnot(qualUniform(c(4,0,0), c(0,1,0))==1)
stopifnot(qualUniform(c(0,4,0))==0)
stopifnot(abs(qualUniform(c(3,2,1))-0.58578) < 0.0001)
stopifnot(abs(qualUniform(c(1,2,3))-0.58578) < 0.0001)
stopifnot(qualUniform(c(1,2,3), c(0,1,0))==1)
stopifnot(abs(qualUniform(c(1,2,3))-0.58578) < 0.0001)
stopifnot(abs(qualUniform(c(1,2,3), c(0,1,1))-0.590316) < 0.0001)
stopifnot(abs(qualUniform(c(2,3), c(1,1))-0.552786) < 0.0001)
stopifnot(abs(qualUniform(c(1:120)-0.38661) < 0.0001)

---

**read.MQ**

*Convenience wrapper for MQDataReader when only a single MQ file should be read and file mapping need not be stored.*

---

**Description**

For params, see MQDataReader::readMQ().

**Usage**

```r
read.MQ(
  file,
  filter = "",
  type = "pg",
  col_subset = NA,
  add_fs_col = 10,
  LFQ_action = FALSE,
  ...
)
```

**Arguments**

- `file` see MQDataReader::readMQ()
- `filter` see MQDataReader::readMQ()
- `type` see MQDataReader::readMQ()
- `col_subset` see MQDataReader::readMQ()
- `add_fs_col` see MQDataReader::readMQ()
- `LFQ_action` see MQDataReader::readMQ()
- `...` see MQDataReader::readMQ()

**Value**

see MQDataReader::readMQ()
renameFile  
*Given a vector of (short/long) filenames, translate to the (long/short) version*

**Description**

Given a vector of (short/long) filenames, translate to the (long/short) version

**Usage**

`renameFile(f_names, mapping)`

**Arguments**

- `f_names`  
  Vector of filenames
- `mapping`  
  A data.frame with from,to columns

**Value**

A vector of translated file names as factor (ordered by mapping!)

---

repEach  
*Repeat each element x_i in X, n_i times.*

**Description**

Repeat each element x_i in X, n_i times.

**Usage**

`repEach(x, n)`

**Arguments**

- `x`  
  Values to be repeated
- `n`  
  Number of repeat for each x_i (same length as x)

**Value**

Vector with values from x, n times

**Examples**

```r
repEach(1:3, 1:3)  # 1, 2, 3, 3, 3
```
Relative standard deviation (RSD)

Description
Simply \( CV \times 100 \)

Usage
\[ \text{RSD}(x) \]

Arguments
\( x \)  Vector of numeric values

Value
\[ \text{RSD} \]

RTalignmentTree  Return a tree plot with a possible alignment tree.

Description
This allows the user to judge which Raw files have similar corrected RT’s (i.e. where aligned successfully). If there are clear sub-clusters, it might be worth introducing artificial fractions into MaxQuant, to avoid ID-transfer between these clusters (use the MBR-Align and MBR-ID-Transfer metrics to support the decision).

Usage
\[ \text{RTalignmentTree}(\text{df_evd}, \text{col_fraction} = \text{c}()) \]

Arguments
\( \text{df_evd} \)  Evidence table containing calibrated retention times and sequence information.
\( \text{col_fraction} \)  Empty vector or 1-values vector giving the name of the fraction column (if existing)

Details
If the input contains fractions, leaf nodes will be colored accordingly. Distinct sub-clusters should have their own color. If not, MaxQuant’s fraction settings should be optimized. Note that introducing fractions in MaxQuant will naturally lead to a clustering here (it’s somewhat circular).

Value
\[ \text{ggplot object containing the correlation tree} \]
**scale01linear**  
*Scales a vector of values linearly to \([0, 1]\) If all input values are equal, returned values are all 0*

**Description**
Scales a vector of values linearly to \([0, 1]\) If all input values are equal, returned values are all 0

**Usage**
```r
scale01linear(X)
```

**Arguments**
- **X**  
  Vector of values

**Value**
Scaled vector

---

**scale_x_discrete_reverse**  
*Inverse the order of items on the x-axis (for discrete scales)*

**Description**
Inverse the order of items on the x-axis (for discrete scales)

**Usage**
```r
scale_x_discrete_reverse(values, ...)
```

**Arguments**
- **values**  
  The vector of values as given to the x aesthetic
- **...**  
  Other arguments forwarded to ’scale_y_discrete()’

**Value**
`ggplot object, concatenatable with ’+’`
scale_y_discrete_reverse

Inverse the order of items on the y-axis (for discrete scales)

Description
Inverse the order of items on the y-axis (for discrete scales)

Usage
scale_y_discrete_reverse(values, ...)

Arguments
values
The vector of values as given to the y aesthetic
...
Other arguments forwarded to 'scale_y_discrete()'

Value
ggplot object, concatenatable with ‘+’

ScoreInAlignWindow

Compute the fraction of features per Raw file which have an acceptable RT difference after alignment

Description
Using the result from 'alignmentCheck()', score the features of every Raw file and see if they have been properly aligned. Returned value is between 0 (bad) and 1 (all aligned).

Usage
ScoreInAlignWindow(data, allowed.deltaRT = 1)

Arguments
data
A data.frame with columns 'rtdiff' and 'raw.file'
allowed.deltaRT
The allowed matching difference (1 minute by default)

Value
A data.frame with one row for each raw.file and columns 'raw.file' and 'withinRT' (0-1)
shortenStrings

Shorten a string to a maximum length and indicate shorting by appending '. '..'

Description

Some axis labels are sometimes just too long and printing them will either squeeze the actual plot (ggplot) or make the labels disappear beyond the margins (graphics::plot) One ad-hoc way of avoiding this is to shorten the names, hoping they are still meaningful to the viewer.

Usage

shortenStrings(x, max_len = 20, verbose = TRUE, allow_duplicates = FALSE)

Arguments

- **x**: Vector of input strings
- **max_len**: Maximum length allowed
- **verbose**: Print which strings were shortened
- **allow_duplicates**: If shortened strings are not discernible any longer, consider the short version valid (not the default), otherwise (default) return the full string (→ no-op)

Details

This function should be applied AFTER you tried more gentle methods, such as delLCP or simplifyNames.

Value

A vector of shortened strings

See Also

delLCP, simplifyNames

Examples

```r
r = shortenStrings(c("gamg_101", "gamg_101230100451", "jurkat_06_100731121305", "jurkat_06_1"))
all(r == c("gamg_101", "gamg_101230100..", "jurkat_06_1007..", "jurkat_06_1"))
```
**simplifyNames**

Removes common substrings (infixes) in a set of strings.

Description

Usually handy for plots, where condition names should be as concise as possible. E.g. you do not want names like 'TK20130501_H2M1_010_IMU008_CISPLA_E3_R1.raw' and 'TK20130501_H2M1_026_IMU008_CISPLA_E7_R2.raw', but rather 'TK..._010_I...E3_R1.raw' and 'TK..._026_I...E7_R2.raw'.

If multiple such substrings exist, the algorithm will remove the longest first and iterate a number of times (two by default) to find the second/third etc longest common substring. Each substring must fulfill a minimum length requirement - if its shorter, its not considered worth removing and the iteration is aborted.

Usage

```r
simplifyNames(
  strings,
  infix_iterations = 2,
  min_LCS_length = 7,
  min_out_length = 7
)
```

Arguments

- **strings**  
  A vector of strings which are to be shortened
- **infix_iterations**  
  Number of successive rounds of substring removal
- **min_LCS_length**  
  Minimum length of the longest common substring (default: 7, minimum: 6)
- **min_out_length**  
  Minimum length of shortest element of output (no shortening will be done which causes output to be shorter than this threshold)

Value

A list of shortened strings, with the same length as the input

Examples

```r
#library(PTXQC)
simplifyNames(c("TK20130501_H2M1_010_IMU008_CISPLA_E3_R1.raw",
                  "TK20130501_H2M1_026_IMU008_CISPLA_E7_R2.raw"),
              infix_iterations = 2)
# --> "TK..._010_I...E3_R1.raw", "TK..._026_I...E7_R2.raw"

try(simplifyNames(c("bla", "foo"), min_LCS_length=5))
# --> error, since min_LCS_length must be >=6
```
**supCount**

Compute shortest prefix length which makes all strings in a vector uniquely identifiable.

**Description**

If there is no unique prefix (e.g. if a string is contained twice), then the length of the longest string is returned, i.e. if the return value is used in a call to substr, nothing happens e.g. substr(x, 1, supCount(x)) == x

**Usage**

```r
supCount(x, prefix_l = 1)
```

**Arguments**

- `x` : Vector of strings
- `prefix_l` : Starting prefix length, which is incremented in steps of 1 until all prefixes are unique (or maximum string length is reached)

**Value**

Integer with minimal prefix length required

**Examples**

```r
supCount(c("abcde...", "abcd...", "abc...")) ## 5
x = c("doubled", "doubled", "aLongDummyString")
all( substr(x, 1, supCount(x)) == x )
## TRUE (no unique prefix due to duplicated entries)
```

---

**theme_blank**

A blank theme (similar to the deprecated theme_blank())

**Description**

A blank theme (similar to the deprecated theme_blank())

**Usage**

```r
theme_blank()
```

**Value**

A ggplot2 object, representing an empty theme
thinOut

*Thin out a data.frame by removing rows with similar numerical values in a certain column.*

**Description**

All values in the numerical column 'filterColname' are assigned to bins of width 'binsize'. Only one value per bin is retained. All other rows are removed and the reduced data frame will all its columns is returned.

**Usage**

thinOut(data, filterColname, binsize)

**Arguments**

- **data**: The data.frame to be filtered
- **filterColname**: Name of the filter column as string
- **binsize**: Width of a bin

**Value**

Data.frame with reduced rows, but identical input columns

thinOutBatch

*Apply 'thinOut' on all subsets of a data.frame, split by a batch column*

**Description**

The binsize is computed from the global data range of the filter column by dividing the range into binCount bins.

**Usage**

thinOutBatch(data, filterColname, batchColname, binCount = 1000)

**Arguments**

- **data**: The data.frame to be split and filtered(thinned)
- **filterColname**: Name of the filter column as string
- **batchColname**: Name of the split column as string
- **binCount**: Number of bins in the 'filterColname' dimension.

**Value**

Data.frame with reduced rows, but identical input columns
wait_for_writable  \hspace{1cm} \textit{Check if a file is writable and blocks an interactive session, waiting for user input.}

\textbf{Description}

This function gives the user a chance to make the output file writeable before a write attempt is actually made by R to avoid having run the whole program again upon write failure.

\textbf{Usage}

\begin{verbatim}
wait_for_writable(
    filename,
    prompt_text = paste0("The file \\
    " is not writable. Please close all applications using this file. Press \\
    " to abort!"),
    abort_answer = "n"
)
\end{verbatim}

\textbf{Arguments}

- \textbf{filename}  \hspace{0.5cm} The file to test for writable
- \textbf{prompt_text}  \hspace{0.5cm} If not writable, show this prompt text to the user
- \textbf{abort_answer}  \hspace{0.5cm} If the user enters this string into the prompt, this function will stop()

\textbf{Details}

Note: The file will not be overwritten or changed by this function.

\textbf{Value}

TRUE if writable, FALSE if aborted by user or (not-writeable and non-interactive)

\textbf{YAMLClass-class}

\textit{Query a YAML object for a certain parameter.}

\textbf{Description}

If the object has the param, then return it. If the param is unknown, create it with the given default value and return the default.

\textbf{Fields}

- \texttt{ymlObj}  \hspace{0.5cm} A Yaml object as created by \texttt{yaml.load}
Methods

getYAML(param_name, default, min = NA, max = NA) Query this YAML object for a certain parameter and return its value. If it does not exist it is created with a default value. An optional min/max range can be specified and will be enforced if the value is known (default will be used upon violation).

setYAML(param_name, value) Set a YAML parameter to a certain value. Overwrites the old value or creates a new entry if hitherto unknown.

writeYAML(filename) Write YAML config (including some documentation) to a YAML file. Returns TRUE on success (always), unless writing the file generates an error.

Examples

yc = YAMLClass$new(list())
val = yc$getYAML("cat\$subCat", "someDefault")
val ## someDefault
val = yc$setYAML("cat\$subCat", "someValue")
val ## someValue
yc$getYAML("cat\$subCat", "someDefault") ## still 'someValue' (since its set already)

Description

A string concatenation function, more readable than 'paste()'.

Usage

a %+% b

Arguments

a Char vector
b Char vector

Value

Concatenated string (no separator)
