Package ‘fitPS’

March 20, 2024

Type Package

Title Fit Zeta Distributions to Forensic Data

Version 1.0.1

Date 2024-03-12

Description Fits Zeta distributions (discrete power laws) to data that arises from forensic surveys of clothing on the presence of glass and paint in various populations. The general method is described to some extent in Coulson, S.A., Buckleton, J.S., Gummer, A.B., and Triggs, C.M. (2001) <doi:10.1016/S1355-0306(01)71847-3>, although the implementation differs.

==.psData  S3 method for objects of class psData

Description

Tests to see if two objects of class psData are equal. That is their type is the same, and the data contained in data is the same. See readData for a description of the psData class.

Usage

## S3 method for class 'psData'
lhs == rhs

Arguments

lhs  an object of class psData.
rhs  an object of class psData.
as.data.frame.psData

Examples

p = readData(system.file("extdata", "p.xlsx", package = "fitPS"))
p1 = makePSData(n = 0:2, count = c(98, 1, 1), type = "P")
p2 = makePSData(n = 0:2, count = c(97, 2, 1), type = "P")
p == p1 ## TRUE
p == p2 ## FALSE
p1 == p2 ## FALSE

as.data.frame.psData  Converts an object of class psData to a data.frame

Description

Converts an object of class psData—see readData—to a data.frame that can be used with in functions in other packages such as vglm to fit more complicated models.

Usage

## S3 method for class 'psData'
as.data.frame(x, ...)

Arguments

x an object of class psData—see readData for more details.

... any other arguments passed to data.frame.

data.frame

Details

If x is a psData object of type "P", i.e. it relates to numbers of groups of glass, then a data.frame with a single variable count will be return where count = rep(x$data$n + 1, x$data$r). The counts have one added to them because the zeta distribution requires that the counts are greater than or equal to one. If x is a psData object of type "P", i.e. it relates to group sizes, then a data.frame with a single variable count will be return where count = rep(x$data$n, x$data$r).

Value

a data.frame with a single variable count. The number of rows in the data.frame is equal to sum(x$data$r).
Examples

```r
p = readData(system.file("extdata", "p.xlsx", package = "fitPS"))
p.df = as.data.frame(p)
table(p.df$count)
p$data
```

---

**bootCI**

*Bootstrap confidence intervals or regions*

**Description**

Use bootstrapping to generate confidence intervals, or confidence regions in the case of the zero-inflated model.

**Usage**

```r
bootCI(x, ...)
```

## Default S3 method:

```r
bootCI(
  x,
  level = 0.95,
  B = 2000,
  model = c("zeta", "ziz"),
  returnBootValues = FALSE,
  silent = FALSE,
  plot = FALSE,
  parallel = TRUE,
  progressBar = FALSE,
  pbopts = list(type = "txt"),
  ...)
```

## S3 method for class `psData`

```r
bootCI(x, ...)
```

## S3 method for class `psFit`

```r
bootCI(x, ...)
```

**Arguments**

- `x` a object either of class `psData`—see `readData` for more details—or of class `psFit`.
- `...` other arguments.
- `level` the confidence level required—restricted to \([0.75, 1]\). This may be a vector, in which case multiple intervals, or confidence regions will be returned.
**bootCI**

the number of bootstrap samples to take.

**model**

which model to fit to the data, either "zeta" or "ziz". Maybe abbreviated to "z" and "zi". Default is "zeta".

**returnBootValues**

if TRUE then the vector (or data.frame) of bootstrapped values is returned. This can be useful for debugging or understanding the results. Default is FALSE.

**silent**

if TRUE, then no output will be displayed whilst the bootstrapping is being undertaken. plot if TRUE then the contours for the confidence region will be plotted. This only works if model = "ziz". It is ignored otherwise. parallel if TRUE then the bootstrapping is performed in parallel.

**plot**

if TRUE and model == "ziz", then a plot of the bootstrapped values will be produced and confidence contour lines will be drawn for each value in level.

**parallel**

if TRUE, then the package will attempt to use multiple cores to speed up computation.

**progressBar**

if TRUE, then progress bars will be displayed to show progress on the bootstrapping.

**pbopts**

a list of arguments for the pboptions function that affect the progress bars. Ignored if progressBar = FALSE.

**Details**

This function uses bootstrapping to compute a confidence interval for the shape parameter in the case of the zeta model and a confidence region in the case of the zero-inflated zeta model. A smoothed bootstrap approach is taken rather than a simple percentile method. The kernel density estimation is performed by the ks package using a smoothed cross-validated bandwidth selection procedure.

**Value**

If returnBootVals == TRUE then the results are returned in a list with elements named ci and bootVals for the zeta model and confRegion and bootVals for the zero-inflated zeta model. The structure of ci and confRegion is described below. If model == "zeta”, then either a vector or a data.frame with elements/columns named "lower" and "upper" representing the lower and upper bounds of the confidence interval(s). Multiple bounds are returned in a data.frame when level has more than one value. If model == "ziz", then a list with length equal to the length of level is returned. The name of each element in the list is the level with list has a single element named "95%". It is possible for there to be multiple contours for the confidence region for a given level. If there is only one contour for each value of level, then each element of the list consists of a list with elements named pi and shape which specify the coordinates of the contour(s) for that level. There is a third element named level which gives the height of the kernel density estimate at that contour. If there are multiple contours for a given value of level then each list element is a list of lists with the structure given above (level, pi, and shape). NOTE: it is quite possible that there are multiple contours for a given height. If you want a way of thinking about this consider a mountain range with two mountains of equal height. If you draw the contours for (almost) any elevation, then you would expect to capture a region from each mountain.
Methods (by class)

• bootCI(default): Bootstrap confidence intervals or regions
• bootCI(psData): Bootstrap confidence intervals or regions
• bootCI(psFit): Bootstrap confidence intervals or regions

Examples

## Not run:
data(Psurveys)
roux = Psurveys$roux
confRegion = bootCI(roux, model = "ziz", parallel = FALSE, plot = TRUE)

## This will not work unless you have the sp package installed
## Count how many of the points lie within the 95% confidence region
lapply(confRegion, function(cr){
  table(sp::point.in.polygon(fit$pi, fit$shape, cr$pi, cr$shape))
})

## End(Not run)

compareSurveys

Compare two surveys on the basis of their shape parameters

Description

Compare two surveys on the basis of their shape parameters

Usage

compareSurveys(x, ...)

## Default S3 method:
compareSurveys(
x,
y,
xname = NULL,
yname = NULL,
alternative = c("two.sided", "less", "greater"),
null.value = 0,
print = TRUE,
...
)

## S3 method for class 'psData'
compareSurveys(x, y, ...)

## S3 method for class 'psFit'
compareSurveys(x, y, ...)

compare.surveys(x, ...)

comp.survs(x, ...)

Arguments

x either an object of class psData—see readData or an object of class psFit—see fitDist.
y either an object of class psData—see readData or an object of class psFit—see fitDist.
xname an optional name for the first survey object.
yname an optional name for the second survey object.
alternative one of "two.sided", "less", or "greater", depending on the type of hypothesis test you wish to carry out. These may be replaced by single letter (or more) abbreviations.
null.value the true value of the difference in the shape parameters under the null hypothesis.
print if TRUE then the function will print summary output to the screen. This lets output be suppressed in situations where the user wants the function to run silently.
...

Details

This function **only** works for the zeta distribution. It does not work for the zero-inflated zeta distribution. If the results from fitting ZIZ models are passed to this function, then it will ignore the zero-inflated part and simply refit a zeta model.

There is very little reason for null.value to be set to be anything other than 0. However it has been included for flexibility.

alternative = "greater" is the alternative that x has a larger shape parameter than y. alternative = "less" is the alternative that x has a smaller shape parameter than y.

Value

The function returns a list of class "htest" with the following elements:

statistic – the test statistic.
p.value – the P-value associated with the estimate.
estimate – the estimated difference in the shape parameters.
null.value – the specified hypothesized value of the difference in shape parameters—0 by default.
stderr – the standard error of the difference.
alternative – a character string describing the alternative hypothesis.
method – a character string describing the method.
data.name – a character string with the names of the two input data sets separated by " and ".
Methods (by class)

- `compareSurveys(default)`: Compare two surveys on the basis of their shape parameters
- `compareSurveys(psData)`: Compare two surveys on the basis of their shape parameters
- `compareSurveys(psFit)`: Compare two surveys on the basis of their shape parameters

Functions

- `compare.surveys()`: Compare two surveys on the basis of their shape parameters
- `comp.survs()`: Compare two surveys on the basis of their shape parameters

Examples

```r
data(Psurveys)
lau = Psurveys$lau
jackson = Psurveys$jackson
compareSurveys(lau, jackson)

# Example with fitted objects - note the function just refits the models
fit.lau = fitDist(lau)
fit.jackson = fitDist(jackson)
compareSurveys(fit.lau, fit.jackson)

# Example with a bigger difference
compareSurveys(Psurveys$roux, lau)
```

---

**compareSurveysLRT**

*Compare two or more surveys on the basis of their shape parameters using a Likelihood Ratio Test*

Description

Compare two or more surveys on the basis of their shape parameters using a Likelihood Ratio Test

Usage

```r
compareSurveysLRT(...)```

Arguments

- `...` two or more objects of class "psData"—see `readData`. 
Details

This function **only** works for the zeta distribution. The function carries out a likelihood ratio test (LRT) to test the null hypothesis

\[ H_0 : \alpha_1 = \alpha_2 = \ldots = \alpha_K \]

versus the alternative

\[ H_1 : \alpha_i \neq \alpha_j \text{ for some } i \neq j \in \{1, \ldots, K\}, \]

where \( \alpha_i \) is the shape parameter for the zeta distribution of the \( i^{th} \) survey.

Value

The function returns a list of class "htest" with the following elements:

- statistic – the test statistic.
- parameter – the degrees of freedom for the test
- p.value – the P-value associated with the estimate.
- method – a character string describing the method hypothesis.
- data.name – the names of the data sets used in the test

Examples

```r
data(Psurveys)
lau = Psurveys$lau
jackson = Psurveys$jackson
compareSurveysLRT(lau, jackson)
# Example with three surveys
roux = Psurveys$roux
compareSurveysLRT(lau, jackson, roux)
```

confint.psFit  
\textit{S3 confint method for objects of class psFit}

Description

S3 confint method for objects of class psFit

Usage

```r
# S3 method for class 'psFit'
confint(object, parm, level = 0.95, ...)
```
Arguments

- **object**: an object of class `psFit`—see `fitDist` for more details.
- **parm**: added for compatibility. Should be left empty as it is ignored.
- **level**: the confidence level required—restricted to [0.75, 1)
- **...**: in theory other parameters to be passed to `confint`, but in reality passed as extra parameters to the internal function `plZIZ`.

Details

**NOTE**: the method for ZIZ model is a little computationally intensive and possibly (almost certainly) unstable.

Value

If the zeta model is used (i.e. object comes from a call to `fitDist`), then a list with two items: `wald` and `prof` containing the Wald and profile likelihood confidence intervals respectively for the shape parameter of the fitted zeta distribution is returned. In general these should be relatively close to each other. **NOTE** These values are for the **VGAM** parameterisation of the Zeta distribution which uses $s' = s - 1$. This means they can be used without alteration in `dzeta`. If a zero-inflated zeta model is used (i.e. object comes from a call to `fitZIDist`) then list of a confidence regions is returned with and element for each value of `level`. The confidence regions are data.frames with variables `pi` and `shape` which can be used with `lines` or `polygon` to draw a the confidence region.

Examples

```r
data(Psurveys)
roux = Psurveys$roux
fit = fitDist(roux)
confint(fit)

## Not run:
fit.zi = fitZIDist(roux)
cr = confint(fit.zi, level = c(0.80, 0.95))
plot(cr[["0.95"]], type = "l")
polygon(cr[["0.8"]])

## End(Not run)
```

**fitDist**

*Fit a Zeta Distribution to Forensic Data*
**Description**

This function uses maximum likelihood estimation (MLE) to estimate the shape parameter of a zeta distribution from a set of observed counts for either the number of groups/sources of forensically interesting material (mostly glass or paint) recovered from clothing, or the number of fragments/particles in each group. This, in turn, allows the estimation of the P and S probabilities, as described by Evett and Buckleton (1990), which used in computing the likelihood ratio (LR) for activity level propositions. The data itself arises from clothing surveys. The general method is described in Coulson et al. (2001), although poor typesetting, and a lack of definition of terms makes it hard to see. This package improves on the estimation in that linear interpolation is not required, and standard numerical optimisation is used instead. The zeta distribution has probability mass function

\[ p(k) = \frac{k^{-s}}{\zeta(s)} \]

where \( \zeta(s) \) is the Reimann Zeta function. Coulson et al. (2001) did not have an easy way to rapidly compute this quantity, hence their use of linear interpolation.

**Usage**

```r
fitDist(x, nterms = 10, start = 1, ...) fitdist(x, nterms = 10, start = 1, ...)
```

**Arguments**

- `x` an object of type `psData`, usually obtained from `readData`.
- `nterms` the number of terms to compute the probability distribution for.
- `start` a starting value for the optimiser.
- `...` other parameters - not currently used.

**Details**

The function returns an object of class `psFit` which is a list contains four elements:

- `psData` an object of class `psData`–see `readData`.
- `fit` the fitted object from `optim`.
- `shape` the maximum likelihood estimate of the shape parameter.
- `var.shape` - the maximum likelihood estimate of the shape parameter.
- `fitted` - a named `vector` containing the first `nterms` of the fitted distribution.
- `model` - set to "zeta" for this model.

The output can be used in a variety of ways. If the interest is just in the shape parameter estimate, then the `shape` member of the `psFit` object contains this information. It is also displayed along with a number of fitted probabilities by the `print.psFit` method. The fitted object can also be plotted using the `plot.psFit` method, and to create a probability function with `probfun`. **NOTE** The value of the shape parameter that is printed (if you print the fitted object) is different from that value that is stored in `shape`. The stored value is for the VGAM parameterisation of the Zeta...
distribution which uses $s' = s - 1$. Therefore the printed value is $s = s' + 1$. If you intend to use the fitted value with `dzeta`, then you should use the stored value $s'$.

If `start` is not specified, then it is chosen randomly from $(0.5, 1)$. The reason the lower value is not zero is that small starting values seem to cause instability in the likelihood. If you specify your own starting value, it would be sensible to keep it above 0.5.

**Value**

an object of class `psFit`—see Details.

**Functions**

- `fitdist()`: Fit a Zeta Distribution to Forensic Data export

**References**

**See Also**

`plot.psFit, print.psFit, probfun`

**Examples**

```r
p = readData(system.file("extdata", "p.xlsx", package = "fitPS"))
fit = fitDist(p)
fit
```

---

**fitted.psFit**

*S3 fitted method for an object of class psFit*

**Description**

S3 fitted method for an object of class `psFit`

**Usage**

```r
## S3 method for class 'psFit'
fitted(object, n = NULL, ...)
```
Arguments

object  
an object of class psFit, usually from fitDist or fitZIDist.

n  
This parameter is NULL by default. If it is not NULL then it must be either the number of fitted terms to be return, or, a vector containing the desired fitted values.

...  
other arguments passed to fitted—not used.

Value

a named vector of fitted probabilities

Description

This function uses maximum likelihood estimation (MLE) to estimate mixing parameter and the shape parameter of a zero-inflated zeta distribution from a set of observed counts for either the number of groups/sources of forensically interesting material (mostly glass or paint) recovered from clothing, or the number of fragments/particles in each group. This, in turn, allows the estimation of the P and S probabilities, as described by Evett and Buckleton (1990), which used in computing the likelihood ratio (LR) for activity level propositions. The data itself arises from clothing surveys. The zero-inflated zeta distribution has probability mass function

\[ p(k) = \begin{cases} 
\pi + \frac{(1-\pi)}{\zeta(s)} , & k = 0, \\
\frac{(1-\pi)k^{-s}}{\zeta(s)} , & k = 1, 2, \ldots 
\end{cases} \]

where \( \zeta(s) \) is the Reimann Zeta function.

Usage

\[ \text{fitZIDist}(x, \text{nterms} = 10, \text{start} = c(0.5, 1), \ldots) \]

\[ \text{fitZIDist}(x, \text{nterms} = 10, \text{start} = c(0.5, 1), \ldots) \]

\[ \text{fitzidist}(x, \text{nterms} = 10, \text{start} = c(0.5, 1), \ldots) \]

Arguments

x  
an object of type psData, usually obtained from readData.

nterms  
the number of terms to compute the probability distribution for.

start  
a starting value for the optimiser.

...  
other parameters - not currently used.
Details

The function returns an object of class \texttt{psFit} which is a list contains seven elements:

- \texttt{psData} – an object of class \texttt{psData}—see \texttt{readData},
- \texttt{fit} – the fitted object from \texttt{optim},
- \texttt{pi} - the maximum likelihood estimate of the mixing parameter,
- \texttt{shape} – the maximum likelihood estimate of the shape parameter,
- \texttt{var.cov} – the estimated variance-covariance matrix for the parameters,
- \texttt{fitted} – a named vector containing the first \texttt{nterms} of the fitted distribution.
- \texttt{model} – set to "ziz" for this model.

The output can be used in a variety of ways. If the interest is just in the mixing and shape parameter estimates, then the \texttt{pi} and \texttt{shape} member of the \texttt{psFit} object contains this information. It is also displayed along with a number of fitted probabilities by the \texttt{print.psFit} method. The fitted object can also be plotted using a number of fitted probabilities by the \texttt{plot.psFit} method. The fitted object can also be plotted using the plot method \texttt{plot.psFit}, and to create a probability function with \texttt{probfun}. **NOTE** The value of the shape parameter that is printed (if you print the fitted object) is different from that value that is stored in shape. The stored value is for the \texttt{VGAM} parameterisation of the zeta distribution which uses $s' = s - 1$. Therefore the printed value is $s = s' + 1$. If you intend to use the fitted value with \texttt{dzeta}, then you should use the stored value $s'$.

If \texttt{start} is not specified, then it is set to (0.5, 1). The reason the starting values are not zero is that small starting values seem to cause instability in the likelihood. If you specify your own starting value, it would be sensible to keep both above 0.5.

Value

an object of class \texttt{psFit}—see Details.

References

See Also

\texttt{plot.psFit, print.psFit, probfun}.

Examples

data(Psurveys)
roux = Psurveys$roux
fit = fitZIDist(roux)
fit
Create a survey data set manually

Description

Create a survey data set from the command line rather than reading data in from a file. This function is likely to be only useful where there are a very small number of group sizes, or sizes of groups of glass.

Usage

makePSData(n, count = NULL, type = c("P", "S"), notes = NULL)
makeData(n, count = NULL, type = c("P", "S"), notes = NULL)
createPSData(n, count = NULL, type = c("P", "S"), notes = NULL)

Arguments

n 
Either the number of groups of glass or the size of different groups of glass, or a vector of observed groups of glass, or group sizes. See details for a longer explanation.

count 
Either the number of people in the survey sample who had n groups of glass on their clothing, or the number of people who had a group of glass of size n.

type 
either "P" or "S"

notes 
a bibentry or a character string which allows extra information about the data to be stored, such as the source, or reference. NULL by default.

Details

If count is NULL, then it is assumed that n consists of actual observed group sizes or numbers of groups of glass found on a survey of N individuals. That is, one could provide n = rep(0:1, 98, 1) or n = 0:1, count = c(98, 1). The former is more useful when performing simulation studies.

Value

an object of type psData—see readData for more details.

See Also

readData
Examples

```r
## recreate the data read in the readData example
p1 = makePSData(n = c(0, 1, 2), count = c(98, 1, 1), type = "P")
s1 = makePSData(n = 1:3, count = c(1, 1, 1), type = "S")
p1
s1
```

---

mean.psData

An S3 method for computing the mean of clothing survey for the number of groups or size of groups

Description

An S3 method for computing the mean of clothing survey for the number of groups or size of groups

Usage

```r
## S3 method for class 'psData'
mean(x, ...)
```

Arguments

- `x` an object of class `psData`—`readData` for more details.
- `...` other arguments which are passed to `sum`

Value

the mean of the data. If there are \( r_i \) observations of the value \( n_i \) then the mean is given by

\[
\frac{\sum_i r_i \times n_i}{\sum_i r_i}.
\]

Examples

```r
data(Psurveys)
mean(Psurveys$roux)
```
Description

S3 plot method for an object of class \texttt{psFit}

Usage

\begin{verbatim}
## S3 method for class 'psFit'
plot(
  x,
  ylim = c(0, 1),
  conf = FALSE,
  conf.level = 0.95,
  ci.type = c("wald", "prof"),
  log.scale = FALSE,
  ...
)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{x} an object of class \texttt{psFit}, usually from \texttt{fitDist} or \texttt{fitZIDist}.
  \item \texttt{ylim} the limits of the y-axis.
  \item \texttt{conf} if \texttt{TRUE}, and the model is the the zeta model (as opposed to the zero-inflated zeta (ZIZ), then confidence intervals (based on the standard error of the shape parameter) are drawn on the plot. If the ZIZ model has been used, then this is ignored.
  \item \texttt{conf.level} the confidence level for the confidence intervals. Must be between 0.75 and 0.99.
  \item \texttt{ci.type} Specifies the type of confidence interval. If \texttt{conf} == \texttt{TRUE}, then then \texttt{ci.type} can be either "wald" "prof" (or an abbreviation), depending on whether the Wald interval or the profile likelihood interval should be used. Note that these are intervals on the shape parameter and not the density heights. Therefore the intervals around the probabilities should not really be thought of as confidence intervals but rather something more similar to a "sensitivity" interval.
  \item \texttt{log.scale} if \texttt{TRUE} the y-axis is changed to a logarithmic (base 10) axis.
  \item \texttt{...} other arguments passed to \texttt{plot}.
\end{itemize}

Value

No return value, called for side effects
Examples

```r
p = readData(system.file("extdata", "p.xlsx", package = "fitPS"))
fit = fitDist(p)
plot(fit)

## An example with Wald generated intervals
plot(fit, conf = TRUE)
plot(fit, conf = TRUE, ci.type = "p")
```

---

**predict.psFit**

*S3 predict method for an object of class psFit*

Description

S3 predict method for an object of class psFit

Usage

```r
## S3 method for class 'psFit'
predict(
  object,
  newdata,
  interval = c("none", "prof", "wald"),
  level = 0.95,
  ...
)
```

Arguments

- **object**: an object of class psFit, usually from `fitDist` or `fitZIDist`.
- **newdata**: an optional vector of integers at which to calculate \( \Pr(X = x) \).
- **interval**: either "none", "prof", or "wald" and can be abbreviated. If "prof" or "wald" AND the zeta model has been used then an interval, based on the bounds of a 100 * level confidence interval for the shape parameter, is given for each predicted probability. The interval is provided based on either a Profile Likelihood, or a Wald, confidence interval for the shape, and therefore cannot really be regarded as a confidence interval for the probabilities. The intervals might be more sensibly regarded as a measure of how sensitive the probabilities are to the choice of shape parameter. NOTE: this parameter is ignored if the Zero-inflated (ZIZ) model has been used.
- **level**: the level of a confidence interval. Ignored if interval == "none".
- **...** other arguments passed to predict—not used

Value

either a named vector of fitted probabilities, or a data.frame with columns predicted, lower, and upper and the row names set to show what terms are being calculated
Examples

```r
data(Psurveys)
roux = Psurveys$roux
fit = fitDist(roux)
predict(fit, interval = "prof")
```

---

print.psData

### S3 print method for an object of class psData

**Description**

S3 print method for an object of class psData

**Usage**

```r
## S3 method for class 'psData'
print(x, ...)
```

**Arguments**

- `x`: an object of class `psData`, usually from `readData` or `makePSData`
- `...`: other arguments passed to `print`

**Value**

No return value, called for side effects.

---

print.psFit

### S3 print method for an object of class psFit

**Description**

S3 print method for an object of class psFit

**Usage**

```r
## S3 method for class 'psFit'
print(x, ...)
```

**Arguments**

- `x`: an object of class `psFit`, usually from `fitDist` or `fitZIDist`
- `...`: other arguments passed to `print`

**Value**

No return value, called for side effects.
**probfun**  

*Probability Functions*

**Description**  
Creates a probability function that allows the computation of any P or S term.

**Usage**  

```r
probfun(psFitobj)
```

**Arguments**  

- `psFitobj`: an object of class `psFit`—see `fitDist` and `fitZIDist`.

**Value**  

a function that can be used to calculate any P or S term.

**Examples**  

```r
p = readData(system.file("extdata", "p.xlsx", package = "fitPS"))
fit = fitDist(p)
P = probfun(fit)
P(0:5)
```

---

**Psveys**  

*Number of Groups of Glass Data*

**Description**  
Count data from six different surveys looking at the number of sources/groups of glass found on the upper surfaces of clothing taken from the general public.

**Usage**  

```r
data(Psveys)
```

**Format**  
A list with nine objects of class `psData`—see `readData` for more details. The elements of the list are named: coulson, jackson, lau, lewis.all, lewis.clothing, lewis.shoes, pettard, ross, and roux, corresponding to the lead author in each of the references given below. lau, pettard, and ross were taken from Coulson et al. (2001) rather than the original source. The three objects starting with lewis represent the combined data (all), the groups of glass found on the outer clothing (clothing), and the groups of glass found on shoes/footwear (shoes).

**readData**

*Read count data from file*

**Description**

 Reads observed counts of either the number of groups or the size of the groups. The file must have only two columns. One of the columns must be labelled P or S and the other count. It does not matter if the column names are in upper case or not. The P column can have labels 0, 1, 2, ... representing the observation of 0, 1, 2, or more groups. The corresponding count column should contain a positive (non-zero) count for each number of groups. Similarly, if the file contains S counts, then the S column can contain labels 1, 2, ... representing the observation of 1, 2, ... fragments in a group. Note that zeros are neither allowed, or useful, in the file as they both simply result in log-likelihood terms of zero, and therefore make no difference.

**Usage**

readData(fileName, notes = NULL, ...)

rzeta

Generate random variates from a zeta distribution

rzeta(n, shape)

Arguments

n
shape

Same as Poisson.
The positive shape parameter \( s = \alpha - 1 \)

See rzeta.
rZIzeta

Generate zero inflated zeta random variates

Description
Generate zero inflated zeta random variates

Usage
rZIzeta(n, pi = 0.5, shape = 1, offset = 0)
rzizeta(n, pi = 0.5, shape = 1, offset = 0)
rzizeta(n, pi = 0.5, shape = 1, offset = 0)

Arguments
- n: the number of observations.
- pi: the mixing parameter for the zero-inflated zeta model—must be in (0, 1).
- shape: the shape parameter for the zero-inflated zeta. Must be greater than zero.
- offset: the zeta distribution returns random variates that are greater than, or equal to one. If the offset is greater than 0, then the distribution is anchored on (has minimum value of) 1 - offset.

Details
Technically this function returns values from the one-inflated zeta distribution. However, if offset is greater than zero (and typically we expect it to be 1), then the minimum random variate value is 1 - offset. We chose the name "zero-inflated zeta" as more people are familiar with zero-inflated models.

Value
a vector of random variates from a zero-inflated zeta model

Examples
data(Psurveys)
roux = Psurveys$roux
fit.zi = fitZIDist(roux)
x = rZIzeta(n = sum(roux$data$rn), pi = fit.zi$pi, shape = fit.zi$shape)
table(x)
**Description**

Count data from six different surveys looking at the number of sources/groups of glass found on the upper surfaces of clothing taken from the general public.

**Usage**

data(Psurveys)

**Format**

A list with five objects of class `psData`—see `readData` for more details. The elements of the list are named: `jackson`, `lau`, `pettard`, `ross`, and `roux`, corresponding to the lead author in each of the references given below. `lau`, `pettard`, and `ross` were taken from Coulson et al. (2001) rather than the original source.

**Source**

**References**

**summary.psFit**

S3 summary method for an object of class psFit

**Description**

S3 summary method for an object of class psFit

**Usage**

```r
## S3 method for class 'psFit'
summary(object, ...)
```

**Arguments**

- `object`: an object of class psFit, usually from `fitDist` or `fitZIDist`
- `...`: other arguments passed to `summary`

**Details**

Experimental because I am unsure if it is useful. If `object` is a zero-inflated zeta fitted object, then the function carries out a likelihood ratio test for the value of pi. Currently not implemented for the logarithmic distribution because we are currently not interested in the logarithmic distribution.

**Value**

No return value, called for side effects

---

**var**

Variance generic

**Description**

Variance generic

**Usage**

```r
var(x, ...)
```

**Arguments**

- `x`: an object for which we want to compute the sample variance.
- `...`: Any additional arguments to be passed to `var`. 
An S3 method for computing the variance of clothing survey for the number of groups or size of groups

Usage

## S3 method for class 'psData'
var(x, ...)

Arguments

x an object of class psData—readData for more details.
...

other arguments which are passed to sum

Value

the mean of the data. If there are \( r_i \) observations of the value \( n_i \) then the variance is computed by \( E[X^2] - E[X]^2 \), where \( E[X] \) is computed using

\[
\sum_i \frac{r_i \times n_i}{\sum_i r_i}
\]

, and \( E[X^2] \) is computed by

\[
\sum_i \frac{r_i \times n_i^2}{\sum_i r_i}
\]

. We realise that the computational formula, \( E[X^2] - E[X]^2 \), is usually not regarded as computationally stable, but the magnitude of the numbers involved is such that, that this is not likely to cause an issue.

Examples

data(Psurveys)
var(Psurveys$roux)
