Package ‘ggpmisc’

May 7, 2024

Type Package
Title Miscellaneous Extensions to 'ggplot2'
Version 0.5.6
Date 2024-05-07
Maintainer Pedro J. Aphalo <pedro.aphalo@helsinki.fi>
Description Extensions to 'ggplot2' respecting the grammar of graphics paradigm. Statistics: locate and tag peaks and valleys; label plot with the equation of a fitted polynomial or other types of models; labels with P-value, R^2 or adjusted R^2 or information criteria for fitted models; label with ANOVA table for fitted models; label with summary for fitted models. Model fit classes for which suitable methods are provided by package 'broom' and 'broom.mixed' are supported. Scales and stats to build volcano and quadrant plots based on outcomes, fold changes, p-values and false discovery rates.

Description

Extensions to ‘ggplot2’ respecting the grammar of graphics paradigm. Statistics: locate and tag peaks and valleys; label plot with the equation of a fitted polynomial or other types of models; labels with P-value, R^2 or adjusted R^2 or information criteria for fitted models; label with ANOVA table for fitted models; label with summary for fitted models. Model fit classes for which suitable methods are provided by package ‘broom’ and ‘broom.mixed’ are supported. Scales and stats to build volcano and quadrant plots based on outcomes, fold changes, p-values and false discovery rates.

Details

The new facilities for cleanly defining new stats and geoms added to ‘ggplot2’ in version 2.0.0 and the support for nested tibbles and new syntax for mapping computed values to aesthetics added to ‘ggplot2’ in version 3.0.0 are used in this package’s code, as well as some features added in more recent updates. This means that current ‘ggpmisc’ versions require recent versions of ggplot2.

Extensions provided:

- Function for conversion of time series data into tibbles that can be plotted with ggplot.
- ggplot() method for time series data.
- Stats for locating and tagging "peaks" and "valleys" (local or global maxima and minima).
- Stat for generating labels from model fit objects, including formatted equations. By default labels are R’s plotmath expressions but LaTeX, markdown and plain text formatted labels are optionally assembled.
- Stats for extracting information from any model fit supported by package ‘broom’ and using it to generate various annotations and data labels.
- Stat for computing and generating labels for the results from multiple comparisons, including adjusted P-values.

The stats for peaks and valleys are coded so as to work correctly both with numeric and POSIXct variables mapped to the x aesthetic. Special handling was needed as text labels are generated from the data.

Note

The signatures of stat_peaks() and stat_valleys() from ‘ggpmisc’ are identical to those of stat_peaks and stat_valleys from package ‘ggspectra’ but the variables returned are a subset as special handling of values related to light spectra is missing. Furthermore the stat_peaks() and stat_valleys() from package ‘ggpmisc’ work correctly when date or datetime values are mapped to the x statistic, while those from package ‘ggspectra’ do not generate correct labels in this case.

Examples

```r
library(tibble)

ggplot(lynx, as.numeric = FALSE) + geom_line() +
  stat_peaks(colour = "red") +
  stat_peaks(geom = "text", colour = "red", angle = 66,
             hjust = -0.1, x.label.fmt = "%Y") +
  ylim(NA, 8000)

formula <- y ~ poly(x, 2, raw = TRUE)
ggplot(cars, aes(speed, dist)) +
  geom_point() +
  stat_poly_line(formula = formula) +
  stat_poly_eq(use_label(c("eq", "R2", "P")),
               formula = formula,
               parse = TRUE) +
  labs(x = expression("Speed, "*x~("mph")),
       y = expression("Stopping distance, "*y~("ft")))

formula <- y ~ x
ggplot(PlantGrowth, aes(group, weight)) +
  stat_summary(fun.data = "mean_se") +
  stat_fit_tb(method = "lm",
              method.args = list(formula = formula),
              tb.type = "fit.anova",
              tb.vars = c(Term = "term", "df", "M.S." = "meansq",
                          "italic(F)" = "statistic",
                          "italic(p)" = "p.value"),
              tb.stat = FALSE)
```

### coef.lmodel2

#### Extract Model Coefficients

**Description**

`coef` is a generic function which extracts model coefficients from objects returned by modeling functions. `coefficients` is an alias for it.

**Usage**

```r
## S3 method for class 'lmodel2'
coef(object, method = "MA", ...)
```

**Arguments**

- `object`: a fitted model object.
- `method`: character One of the methods available in `object`.
- `...`: ignored by this method.

**Details**

Function `lmodel2()` from package `lmodel2` returns a fitted model object of class "lmodel2" which differs from that returned by `lm()`. Here we implement a `coef()` method for objects of this class. It differs from de generic method and that for `lm` objects in having an additional formal parameter `method` that must be used to select estimates based on which of the methods supported by `lmodel2()` are to be extracted. The returned object is identical in its structure to that returned by `coef.lm()`.

**Value**

A named numeric vector of length two.

**See Also**

`lmodel2`
Confidence Intervals for Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted model. This a method for objects inheriting from class "lmodel2".

Usage

```r
## S3 method for class 'lmodel2'
confint(object, parm, level = 0.95, method = "MA", ...)
```

Arguments

- `object`: a fitted model object.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required. Currently only 0.95 accepted.
- `method`: character One of the methods available in `object`.
- `...`: ignored by this method.

Details

Function `lmodel2()` from package 'lmodel2' returns a fitted model object of class "lmodel2" which differs from that returned by `lm()`. Here we implement a `confint()` method for objects of this class. It differs from the generic method and that for `lm` objects in having an additional formal parameter `method` that must be used to select estimates based on which of the methods supported by `lmodel2()` are to be extracted. The returned object is identical in its structure to that returned by `confint.lm()`.

Value

A data frame with two rows and three columns.

See Also

`lmodel2`
**find_peaks**

*Find local maxima or global maximum (peaks)*

**Description**

This method finds peaks (local maxima) in a vector, using a user selectable span and size threshold relative to the tallest peak (global maximum).

**Usage**

```r
find_peaks(x, ignore_threshold = 0, span = 3, strict = FALSE, na.rm = FALSE)
```

**Arguments**

- `x` numeric vector.
- `ignore_threshold` numeric value between 0.0 and 1.0 indicating the size threshold below which peaks will be ignored, or a negative value >= -1, to ignore peaks above a threshold. These values are relative to the range of `x`.
- `span` a peak is defined as an element in a sequence which is greater than all other elements within a window of width span centered at that element. The default value is 3, meaning that a peak is bigger than both of its neighbors. `span = NULL` extends the span to the whole length of `x`.
- `strict` logical flag: if TRUE, an element must be strictly greater than all other values in its window to be considered a peak. Default: TRUE.
- `na.rm` logical indicating whether NA values should be stripped before searching for peaks.

**Details**

This function is a wrapper built onto function `peaks` from `splus2R` and handles non-finite (including NA) values differently than peaks, instead of giving an error when `na.rm = FALSE` and `x` contains NA values, NA values are replaced with the smallest finite value in `x`. `span = NULL` is treated as a special case and returns `max(x)`.

**Value**

A vector of logical values. Values that are TRUE correspond to local peaks in vector `x` and can be used to extract the rows corresponding to peaks from a data frame.

**Note**

The default for parameter `strict` is FALSE in functions `peaks()` and `find_peaks()`, as in `stat_peaks()` and in `stat_valleys()`, while the default in `peaks` is `strict = TRUE`. 
keep_tidy

Tidy, glance or augment an object keeping a trace of its origin

Description

Methods implemented in package 'broom' to tidy, glance and augment the output from model fits return a consistently organized tibble with generic column names. Although this simplifies later steps in the data analysis and reporting, it drops key information needed for interpretation. keep_tidy() makes it possible to retain fields from the model fit object passed as argument to parameter x in the attribute "fn". The class of x is always stored, and by default also fields "call", "terms", "formula", "fixed" and "random" if available.

Usage

keep_tidy(x, ..., to.keep = c("call", "terms", "formula", "fixed", "random"))
keep_glance(x, ..., to.keep = c("call", "terms", "formula", "fixed", "random"))
keep_augment(
  x,
...,
    to.keep = c("call", "terms", "formula", "fixed", "random")
  )

Arguments

x    An object for which tidy(), glance and/or augment method is available.
...
    Other named arguments passed along to tidy(), glance or augment.
to.keep  character vector of field names in x to copy to attribute "fm" of the tibble returned by tidy(), glance or augment.

Details

Functions keep_tidy(), keep_glance or keep_augment are simple wrappers of the generic methods which make it possible to add to the returned values an attribute named "fm" preserving user selected fields and class of the model fit object. Fields names in to.keep missing in x are silently ignored.

Examples

# these examples can only be run if package 'broom' is available
if (requireNamespace("broom", quietly = TRUE)) {
  library(broom)
  mod <- lm(mpg ~ wt + qsec, data = mtcars)
  attr(keep_tidy(mod), "fm")[["class"]]
  attr(keep_glance(mod), "fm")[["class"]]
  attr(keep_augment(mod), "fm")[["class"]]
  attr(keep_tidy(summary(mod)), "fm")[["class"]]
  library(MASS)
  rmod <- rlm(mpg ~ wt + qsec, data = mtcars)
  attr(keep_tidy(rmod), "fm")[["class"]]
}

---

Moved  Moved to package 'gginnards'

Description

Some stats, geoms and the plot layer manipulation functions have been moved from package 'ggpmisc' to a separate new package called 'gginnards'.
outcome2factor

Details
To continue using any of these functions and methods, simply run at the R prompt or add to your script library(gginnards), after installing package 'gginnards'.

See Also

gginnards-package, geom_null, stat_debug_group, stat_debug_panel, geom_debug and delete_layers.

outcome2factor, Convert numeric ternary outcomes into a factor

Description
Convert numeric ternary outcomes into a factor

Usage
outcome2factor(x, n.levels = 3L)
threshold2factor(x, n.levels = 3L, threshold = 0)

Arguments
x a numeric vector of -1, 0, and +1 values, indicating down-regulation, uncertain response or up-regulation, or a numeric vector that can be converted into such values using a pair of thresholds.
n.levels numeric Number of levels to create, either 3 or 2.
threshold numeric vector Range enclosing the values to be considered uncertain.

Details
These functions convert the numerically encoded values into a factor with the three levels "down", "uncertain" and "up", or into a factor with two levels de and uncertain as expected by default by scales scale_colour_outcome, scale_fill_outcome and scale_shape_outcome. When n.levels = 2 both -1 and +1 are merged to the same level of the factor with label "de".

Note
These are convenience functions that only save some typing. The same result can be achieved by a direct call to factor and comparisons. These functions aim at making it easier to draw volcano and quadrant plots.

See Also
Other Functions for quadrant and volcano plots: FC_format(), scale_colour_outcome(), scale_shape_outcome(), scale_y_Pvalue(), xy_outcomes2factor()
Other scales for omics data: scale_colour_logFC(), scale_shape_outcome(), scale_x_logFC(), xy_outcomes2factor()
Examples

outcome2factor(c(-1, 1, 0, 1))
outcome2factor(c(-1, 1, 0, 1), n.levels = 2L)

threshold2factor(c(-0.1, -2, 0, +5))
threshold2factor(c(-0.1, -2, 0, +5), n.levels = 2L)
threshold2factor(c(-0.1, -2, 0, +5), threshold = c(-1, 1))

Model Predictions

Description

predict is a generic function for predictions from the results of various model fitting functions. predict.lmodel2 is the method for model fit objects of class "lmodel2".

Usage

## S3 method for class 'lmodel2'
predict(
  object,
  method = "MA",
  newdata = NULL,
  interval = c("none", "confidence"),
  level = 0.95,
  ...
)

Arguments

object a fitted model object.
method character One of the methods available in object.
newdata An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
interval Type of interval calculation.
level the confidence level required. Currently only 0.95 accepted.
... ignored by this method.

Details

Function lmodel2() from package 'lmodel2' returns a fitted model object of class "lmodel2" which differs from that returned by lm(). Here we implement a predict() method for objects of this class. It differs from the generic method and that for lm objects in having an additional formal parameter method that must be used to select which of the methods supported by lmodel2() are to be used in the prediction. The returned object is similar in its structure to that returned by predict.lm() but lacking names or rownames.
Value

If `interval = "none"` a numeric vector is returned, while if `interval = "confidence"` a data frame with columns `fit`, `lwr` and `upr` is returned.

`lmodel2`

scale_colour_logFC

Colour and fill scales for log fold change data

Description

Continuous scales for colour and fill aesthetics with defaults suitable for values expressed as log2 fold change in data and fold-change in tick labels. Supports tick labels and data expressed in any combination of fold-change, log2 fold-change and log10 fold-change. Supports addition of units to legend title passed as argument to the `name` formal parameter.

Usage

```r
scale_colour_logFC(
  name = "Abundance of y%unit",
  breaks = NULL,
  labels = NULL,
  limits = symmetric_limits,
  oob = scales::squish,
  expand = expansion(mult = 0.05, add = 0),
  log.base.labels = FALSE,
  log.base.data = 2L,
  midpoint = NULL,
  low.colour = "dodgerblue2",
  mid.colour = "grey50",
  high.colour = "red",
  na.colour = "black",
  aesthetics = "colour",
  ...
)
```

```r
scale_color_logFC(
  name = "Abundance of y%unit",
  breaks = NULL,
  labels = NULL,
  limits = symmetric_limits,
  oob = scales::squish,
  expand = expansion(mult = 0.05, add = 0),
  log.base.labels = FALSE,
  log.base.data = 2L,
)```

scale_colour_logFC

midpoint = NULL,
low.colour = "dodgerblue2",
mid.colour = "grey50",
high.colour = "red",
na.colour = "black",
aesthetics = "colour",
...
)

scale_fill_logFC(
  name = "Abundance of y\% unit",
  breaks = NULL,
  labels = NULL,
  limits = symmetric_limits,
  oob = scales::squish,
  expand = expansion(mult = 0.05, add = 0),
  log.base.labels = FALSE,
  log.base.data = 2L,
  midpoint = 1,
  low.colour = "dodgerblue2",
  mid.colour = "grey50",
  high.colour = "red",
  na.colour = "black",
  aesthetics = "fill",
  ...
)

Arguments

name
  The name of the scale without units, used for the legend title.

breaks
  The positions of ticks or a function to generate them. Default varies depending
  on argument passed to log.base.labels. if supplied as a numeric vector they
  should be given using the data as passed to parameter data.

labels
  The tick labels or a function to generate them from the tick positions. The default
  is function that uses the arguments passed to log.base.data and log.base.labels
  to generate suitable labels.

limits
  limits One of: NULL to use the default scale range from ggplot2. A numeric
  vector of length two providing limits of the scale, using NA to refer to the ex-
  isting minimum or maximum. A function that accepts the existing (automatic)
  limits and returns new limits. The default is function symmetric_limits() which keep 1 at the middle of the axis..

oob
  Function that handles limits outside of the scale limits (out of bounds). The default squishes out-of-bounds values to the boundary.

expand
  Vector of range expansion constants used to add some padding around the data,
  to ensure that they are placed some distance away from the axes. The default is
  to expand the scale by 15% on each end for log-fold-data, so as to leave space
  for counts annotations.
log.base.labels, log.base.data
integer or logical Base of logarithms used to express fold-change values in tick labels and in data. Use FALSE for no logarithm transformation.

midpoint numeric Value at the middle of the colour gradient, defaults to FC = 1, assuming data is expressed as logarithm.

low.colour, mid.colour, high.colour, na.colour character Colour definitions to use for the gradient extremes and middle.

aesthetics Character string or vector of character strings listing the name(s) of the aesthetic(s) that this scale works with. This can be useful, for example, to apply colour settings to the colour and fill aesthetics at the same time, via aesthetics = c("colour", "fill").

... other named arguments passed to scale_y_continuous.

Details
These scales only alter default arguments of scale_colour_gradient2() and scale_fill_gradient2(). Please, see documentation for scale_continuous for details. The name argument supports the use of "%unit" at the end of the string to automatically add a units string, otherwise user-supplied values for names, breaks, and labels work as usual. Tick labels in the legend are built based on the transformation already applied to the data (log2 by default) and a possibly different log transformation (default is fold-change with no transformation). The default for handling out of bounds values is to "squish" them to the extreme of the scale, which is different from the default used in 'ggplot2'.

See Also
Other scales for omics data: outcome2factor(), scale_shape_outcome(), scale_x_logFC(), xy_outcomes2factor()

Examples

ggplot(my.df, aes(x, y, colour = y)) + geom_point(shape = "circle", size = 2.5) + scale_x_logFC() + scale_y_logFC() + scale_colour_logFC()

ggplot(my.df, aes(x, y, fill = y)) + geom_point(shape = "circle filled", colour = "black", size = 2.5) + scale_x_logFC() + scale_y_logFC() + scale_fill_logFC()

my.labels <- scales::trans_format(function(x) {log10(2^x)}, scales::math_format())
ggplot(my.df, aes(x, y, colour = y)) +

scale_colour_outcome

Colour and fill scales for ternary outcomes

Description

Manual scales for colour and fill aesthetics with defaults suitable for the three way outcome from some statistical tests.

Usage

scale_colour_outcome(
    ..., 
    name = "Outcome", 
    ns.colour = "grey80", 
    up.colour = "red", 
)
down.colour = "dodgerblue2",
decolour = "goldenrod",
na.colour = "black",
values = "outcome:updown",
drop = TRUE,
aesthetics = "colour"
)

scale_color_outcome(
  ..., 
  name = "Outcome",
nscolour = "grey80",
up.colour = "red",
down.colour = "dodgerblue2",
decolour = "goldenrod",
na.colour = "black",
values = "outcome:updown",
drop = TRUE,
aesthetics = "colour"
)

scale_fill_outcome(
  ..., 
  name = "Outcome",
nscolour = "grey80",
up.colour = "red",
down.colour = "dodgerblue2",
decolour = "goldenrod",
na.colour = "black",
values = "outcome:both",
drop = TRUE,
aesthetics = "fill"
)

Arguments

... other named arguments passed to scale_colour_manual.
name The name of the scale, used for the axis-label.
nscolour, down.colour, up.colour, decolour
The colour definitions to use for each of the three possible outcomes.
na.colour colour definition used for NA.
values a set of aesthetic values to map data values to. The values will be matched in order (usually alphabetical) with the limits of the scale, or with breaks if provided. If this is a named vector, then the values will be matched based on the names instead. Data values that don’t match will be given na.value. In addition the special values "outcome:updown", "outcome:de" and "outcome:both" set predefined values, with "outcome:both" as default.
scale_colour_outcome

drop logical Should unused factor levels be omitted from the scale? The default, TRUE, uses the levels that appear in the data; FALSE uses all the levels in the factor.

aesthetics Character string or vector of character strings listing the name(s) of the aesthetic(s) that this scale works with. This can be useful, for example, to apply colour settings to the colour and fill aesthetics at the same time, via aesthetics = c("colour", "fill").

Details

These scales only alter the breaks, values, and na.value default arguments of scale_colour_manual() and scale_fill_manual(). Please, see documentation for scale_manual for details.

Note

In ‘ggplot2’ (3.3.4, 3.3.5, 3.3.6) scale_colour_manual() and scale_fill_manual() do not obey drop, most likely due to a bug as this worked in version 3.3.3 and earlier. This results in spurious levels in the plot legend when using versions 3.3.4, 3.3.5, 3.3.6 of ‘ggplot2’.

See Also

Other Functions for quadrant and volcano plots: FC_format(), outcome2factor(), scale_shape_outcome(), scale_y_Pvalue(), xy_outcomes2factor()

Examples

```
set.seed(12346)
outcome <- sample(c(-1, 0, +1), 50, replace = TRUE)
my.df <- data.frame(x = rnorm(50),
                     y = rnorm(50),
                     outcome2 = outcome2factor(outcome, n.levels = 2),
                     outcome3 = outcome2factor(outcome))

ggplot(my.df, aes(x, y, colour = outcome3)) +
       geom_point() +
       scale_colour_outcome() +
       theme_bw()

ggplot(my.df, aes(x, y, colour = outcome2)) +
       geom_point() +
       scale_colour_outcome() +
       theme_bw()

ggplot(my.df, aes(x, y, fill = outcome3)) +
       geom_point(shape = 21) +
       scale_fill_outcome() +
       theme_bw()
```
shape_scale_outcome  

Shape scale for ternary outcomes

Description

Manual scales for colour and fill aesthetics with defaults suitable for the three way outcome from some statistical tests.

Usage

```r
scale_shape_outcome(
  ..., 
  name = "Outcome",
  ns.shape = "circle filled",
  up.shape = "triangle filled",
  down.shape = "triangle down filled",
  de.shape = "square filled",
  na.shape = "cross"
)
```

Arguments

- `...`: other named arguments passed to `scale_manual`
- `name`: The name of the scale, used for the axis-label.
- `ns.shape, down.shape, up.shape, de.shape`: The shapes to use for each of the three possible outcomes.
- `na.shape`: Shape used for NA.

Details

These scales only alter the values, and `na.value` default arguments of `scale_shape_manual()`. Please, see documentation for `scale_manual` for details.

  scale_fill_outcome(name = "significance") +
  theme_bw()
```

---

**scale_x_logFC**

*Position scales for log fold change data*

**Description**

Continuous scales for x and y aesthetics with defaults suitable for values expressed as log2 fold change in data and fold-change in tick labels. Supports tick labels and data expressed in any combination of fold-change, log2 fold-change and log10 fold-change. Supports addition of units to axis labels passed as argument to the `name` formal parameter.

**Usage**

```r
scale_x_logFC(
  name = "Abundance of xUnit",
  breaks = NULL,
  labels = NULL,
  limits = symmetric_limits,
  oob = scales::squish,
```
expanding the scale by 15% on each end for log-fold-data, so as to leave space for counts annotations.

log.base.labels, log.base.data
integer or logical Base of logarithms used to express fold-change values in tick labels and in data. Use FALSE for no logarithm transformation.

... other named arguments passed to scale_y_continuous.

Details
These scales only alter default arguments of scale_x_continuous() and scale_y_continuous(). Please, see documentation for scale_continuous for details. The name argument supports the
use of "%unit" at the end of the string to automatically add a units string, otherwise user-supplied values for names, breaks, and labels work as usual. Tick labels are built based on the transformation already applied to the data (log2 by default) and a possibly different log transformation (default is fold-change with no transformation). The default for handling out of bounds values is to "squish" them to the extreme of the scale, which is different from the default used in 'ggplot2'.

See Also

Other scales for omics data: outcome2factor(), scale_colour_logFC(), scale_shape_outcome(), xy_outcomes2factor()

Examples

set.seed(12346)
my.df <- data.frame(x = rnorm(50, sd = 4), y = rnorm(50, sd = 4))
# we assume that both x and y values are expressed as log2 fold change

ggplot(my.df, aes(x, y)) +
  geom_point() +
  scale_x_logFC() +
  scale_y_logFC()

ggplot(my.df, aes(x, y)) +
  geom_point() +
  scale_x_logFC(labels = scales::trans_format(function(x) {log10(2^x)},
                scales::math_format())) +
  scale_y_logFC(labels = scales::trans_format(function(x) {log10(2^x)},
                scales::math_format()))

ggplot(my.df, aes(x, y)) +
  geom_point() +
  scale_x_logFC(log.base.labels = 2) +
  scale_y_logFC(log.base.labels = 2)

ggplot(my.df, aes(x, y)) +
  geom_point() +
  scale_x_logFC("A concentration%unit", log.base.labels = 10) +
  scale_y_logFC("B concentration%unit", log.base.labels = 10)

ggplot(my.df, aes(x, y)) +
  geom_point() +
  scale_x_logFC("A concentration%unit", breaks = NULL) +
  scale_y_logFC("B concentration%unit", breaks = NULL)

# taking into account that data are expressed as log2 FC.
ggplot(my.df, aes(x, y)) +
  geom_point() +
  scale_x_logFC("A concentration%unit", breaks = log2(c(1/100, 1, 100))) +
  scale_y_logFC("B concentration%unit", breaks = log2(c(1/100, 1, 100)))

ggplot(my.df, aes(x, y)) +
scale_y_Pvalue

Convenience scale for P-values

Description

Scales for y aesthetic mapped to P-values as used in volcano plots with transcriptomics and metabolomics data.

Usage

scale_y_Pvalue(
  ..., 
  name = expression(italic(P) - plain(value)),
  transform = NULL,
  breaks = NULL,
  labels = NULL,
  limits = c(1, 1e-20),
  oob = NULL,
  expand = NULL
)

scale_y_FDR(
  ..., 
  name = "False discovery rate",
  transform = NULL,
scale_y_Pvalue

breaks = NULL,
labels = NULL,
limits = c(1, 1e-10),
oob = NULL,
expand = NULL
)

scale_x_Pvalue(

...,
name = expression(italic(P) - plain(value)),
transform = NULL,
breaks = NULL,
labels = NULL,
limits = c(1, 1e-20),
oob = NULL,
expand = NULL
)

scale_x_FDR(

...,
name = "False discovery rate",
transform = NULL,
breaks = NULL,
labels = NULL,
limits = c(1, 1e-10),
oob = NULL,
expand = NULL
)

Arguments

... other named arguments passed to scale_y_continuous.
name The name of the scale without units, used for the axis-label.
transform Either the name of a transformation object, or the object itself. Use NULL for the default.
breaks The positions of ticks or a function to generate them. Default varies depending on argument passed to log.base.labels.
labels The tick labels or a function to generate them from the tick positions. The default is function that uses the arguments passed to log.base.data and log.base.labels to generate suitable labels.
limits Use one of: NULL to use the default scale range, a numeric vector of length two providing limits of the scale; NA to refer to the existing minimum or maximum; a function that accepts the existing (automatic) limits and returns new limits.
oob Function that handles limits outside of the scale limits (out of bounds). The default squishes out-of-bounds values to the boundary.
expand Vector of range expansion constants used to add some padding around the data, to ensure that they are placed some distance away from the axes. The default is
to expand the scale by 15% on each end for log-fold-data, so as to leave space for counts annotations.

Details

These scales only alter default arguments of `scale_x_continuous()` and `scale_y_continuous()`. Please, see documentation for `scale_continuous` for details.

```

---

**stat_correlation**

Annotate plot with correlation test

**Description**

`stat_correlation()` applies `stats::cor.test()` respecting grouping with method = "pearson" default but alternatively using "kendall" or "spearman" methods. It generates labels for correlation coefficients and p-value, coefficient of determination ($R^2$) for method "pearson" and number of observations.

**Usage**

```r
stat_correlation(
  mapping = NULL,
  data = NULL,
  geom = "text_npc",
  position = "identity",
  ...
)```

```r
```
method = "pearson",
n.min = 2L,
alternative = "two.sided",
exact = NULL,
\text{r.conf.level} = \text{ifelse}(\text{method} == "\text{pearson}\), 0.95, NA),
continuity = FALSE,
small.r = FALSE,
small.p = FALSE,
coefficient.zeros = TRUE,
r.digits = 2,
t.digits = 3,
p.digits = 3,
CI.brackets = \text{c}([", "]
,label.x = "\text{left}\),
label.y = "\text{top}\),
hstep = 0,
vstep = NULL,
output.type = NULL,
\text{boot.R} = \text{ifelse}(\text{method} == "\text{pearson}\), 0, 999)
na.rm = FALSE,
parse = NULL,
\text{show.legend} = FALSE,
\text{inherit.aes} = TRUE
)

\textbf{Arguments}

\textbf{mapping} \hspace{1cm} \text{The aesthetic mapping, usually constructed with \texttt{aes}. Only needs to be set at the layer level if you are overriding the plot defaults.}

\textbf{data} \hspace{1cm} A layer specific dataset, only needed if you want to override the plot defaults.

\textbf{geom} \hspace{1cm} The geometric object to use display the data

\textbf{position} \hspace{1cm} The position adjustment to use for overlapping points on this layer

\textbf{method} \hspace{1cm} character One of "pearson", "kendall" or "spearman".

\textbf{n.min} \hspace{1cm} integer Minimum number of distinct values in the variables for fitting to the attempted.

\textbf{alternative} \hspace{1cm} character One of "two.sided", "less" or "greater".

\textbf{exact} \hspace{1cm} logical Whether an exact p-value should be computed. Used for Kendall’s tau and Spearman’s rho.

\textbf{r.conf.level} \hspace{1cm} numeric Confidence level for the returned confidence interval. If set to NA computation of CI is skipped.

\textbf{continuity} \hspace{1cm} logical If TRUE, a continuity correction is used for Kendall’s tau and Spearman’s rho when not computed exactly.
small.r, small.p

logical Flags to switch use of lower case r and p for coefficient of correlation (only for method = "pearson") and p-value.

coeff.keep.zeros

logical Keep or drop trailing zeros when formatting the correlation coefficients and t-value, z-value or S-value (see note below).

r.digits, t.digits, p.digits

integer Number of digits after the decimal point to use for R, r.squared, tau or rho and P-value in labels. If Inf, use exponential notation with three decimal places.

CI.brackets

character vector of length 2. The opening and closing brackets used for the CI label.

label.x, label.y

numeric with range 0..1 "normalized parent coordinates" (npc units) or character if using geom_text_npc() or geom_label_npc(). If using geom_text() or geom_label() numeric in native data units. If too short they will be recycled.

hstep, vstep

numeric in npc units, the horizontal and vertical displacement step-size used between labels for different groups.

output.type

character One of "expression", "LaTeX", "text", "markdown" or "numeric".

boot.R

integer The number of bootstrap resamples. Set to zero for no bootstrap estimates for the CI.

na.rm

a logical indicating whether NA values should be stripped before the computation proceeds.

parse

logical Passed to the geom. If TRUE, the labels will be parsed into expressions and displayed as described in ?plotmath. Default is TRUE if output.type = "expression" and FALSE otherwise.

show.legend

logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes

If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

This statistic can be used to annotate a plot with the correlation coefficient and the outcome of its test of significance. It supports Pearson, Kendall and Spearman methods to compute correlation. This statistic generates labels as R expressions by default but LaTeX (use TikZ device), markdown (use package 'ggtext') and plain text are also supported, as well as numeric values for user-generated text labels. The character labels include the symbol describing the quantity together with the numeric value. For the confidence interval (CI) the default is to follow the APA recommendation of using square brackets.

The value of parse is set automatically based on output-type, but if you assemble labels that need parsing from numeric output, the default needs to be overridden. By default the value of output.type is guessed from the name of the geometry.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. cor.test() is always applied.
to the variables mapped to the x and y aesthetics, so the scales used for x and y should both be continuous scales rather than discrete.

Aesthetics

`stat_correlation()` requires x and y. In addition, the aesthetics understood by the geom ("text" is the default) are understood and grouping respected.

Computed variables

If output.type is "numeric" the returned tibble contains the columns listed below with variations depending on the method. If the model fit function used does not return a value, the variable is set to \texttt{NA\_real\_}.

\begin{itemize}
  \item \texttt{x, npcx} x position
  \item \texttt{y, npcy} y position
  \item r, and cor, tau or rho numeric values for correlation coefficient estimates
  \item t.value and its df, \texttt{z.value or S.value} numeric values for statistic estimates
  \item p.value, n numeric values.
  \item r.conf.level numeric value, as fraction of one.
  \item r.confint.low Confidence interval limit for r.
  \item r.confint.high Confidence interval limit for r.
  \item grp.label Set according to mapping in \texttt{aes}.
  \item method.label Set according method used.
  \item method, test character values
\end{itemize}

If output.type different from "numeric" the returned tibble contains in addition to the columns listed above those listed below. If the numeric value is missing the label is set to \texttt{character(0L)}.

\begin{itemize}
  \item r.label, and cor.label, tau.label or rho.label Correlation coefficient as a character string.
  \item t.value.label, z.value.label or S.value.label t-value and degrees of freedom, z-value or S-value as a character string.
  \item p.value.label P-value for test against zero, as a character string.
  \item r.confint.label, and cor.confint.label, tau.confint.label or rho.confint.label Confidence interval for r (only with method = "pearson").
  \item n.label Number of observations used in the fit, as a character string.
  \item grp.label Set according to mapping in \texttt{aes}, as a character string.
\end{itemize}

To explore the computed values returned for a given input we suggest the use of \texttt{geom\_debug} as shown in the last examples below.

Note

Currently \texttt{coef.keep.zeros} is ignored, with trailing zeros always retained in the labels but not protected from being dropped by R when character strings are parsed into expressions.
See Also

`cor.test` for details on the computations.

Examples

```r
# generate artificial data
set.seed(4321)
x <- (1:100) / 10
y <- x + rnorm(length(x))
my.data <- data.frame(x = x,
                      y = y,
                      y.desc = -y,
                      group = c("A", "B"))

    stat_correlation(geom = "debug", method = "pearson")
stat_fit_augment

Augment data with fitted values and statistics

Description

stat_fit_augment fits a model and returns a "tidy" version of the model's data with prediction added, using `augment()` methods from packages 'broom', 'broom.mixed', or other sources. The prediction can be added to the plot as a curve.

Usage

```r
stat_fit_augment(
  mapping = NULL,
  data = NULL,
  geom = "smooth",
  method = "lm",
  method.args = list(formula = y ~ x),
  n.min = 2L,
  augment.args = list(),
  level = 0.95,
  y.out = ".fitted",
  position = "identity",
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = TRUE,
)```
Arguments

- **mapping**: The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
- **data**: A layer specific dataset - only needed if you want to override the plot defaults.
- **geom**: The geometric object to use display the data
- **method**: character or function.
- **method.args, augment.args**: list of arguments to pass to `method` and to `broom::augment`.
- **n.min**: integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.
- **level**: numeric Level of confidence interval to use (0.95 by default)
- **y.out**: character (or numeric) index to column to return as y.
- **position**: The position adjustment to use for overlapping points on this layer
- **na.rm**: logical indicating whether NA values should be stripped before the computation proceeds.
- **show.legend**: logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
- **inherit.aes**: If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. `borders`.
- **...**: other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.

Details

`stat_fit_augment` together with `stat_fit_glance` and `stat_fit_tidy`, based on package 'broom' can be used with a broad range of model fitting functions as supported at any given time by 'broom'. In contrast to `stat_poly_eq` which can generate text or expression labels automatically, for these functions the mapping of aesthetic `label` needs to be explicitly supplied in the call, and labels built on the fly.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. In other words, it respects the grammar of graphics and consequently within arguments passed through `method.args` names of aesthetics like $x$ and $y$ should be used instead of the original variable names, while data is automatically passed the data frame. This helps ensure that the model is fitted to the same data as plotted in other layers.

Warning!

Not all `glance()` methods are defined in package 'broom'. `glance()` specializations for mixed models fits of classes 'lme', 'nlme', 'lme4', and many others are defined in package 'broom.mixed'.
Handling of grouping

`stat_fit_augment` applies the function given by `method` separately to each group of observations; in ggplot2 factors mapped to aesthetics generate a separate group for each level. Because of this, `stat_fit_augment` is not useful for annotating plots with results from `t.test()` or ANOVA or ANCOVA. In such cases use instead `stat_fit_tb()` which applies the model fitting per panel.

Computed variables

The output of `augment()` is returned as is, except for `y` which is set based on `y.out` and `y.observed` which preserves the `y` returned by the `generics:::augment` methods. This renaming is needed so that the geom works as expected.

To explore the values returned by this statistic, which vary depending on the model fitting function and model formula we suggest the use of `geom_debug`. An example is shown below.

Note

The statistic `stat_fit_augment` can be used only with `methods` that accept formulas under any formal parameter name and a `data` argument. Use `ggplot2::stat_smooth()` instead of `stat_fit_augment` in production code if the additional features are not needed.

Although arguments passed to parameter `augment.args` will be passed to `[generics:::augment()]` whether they are silently ignored or obeyed depends on each specialization of `[augment()]`, so do carefully read the documentation for the version of `[augment()]` corresponding to the ‘method’ used to fit the model.

See Also

`broom` and `broom.mixed` for details on how the tidying of the result of model fits is done.

  stat_fit_augment(method = "rq")

stat_fit_deviations  Residuals from model fit as segments

Description

stat_fit_deviations fits a linear model and returns fitted values and residuals ready to be plotted as segments.

Usage

stat_fit_deviations(
  mapping = NULL,
  data = NULL,
  geom = "segment",
  method = "lm",
  method.args = list(),
  n.min = 2L,
  formula = NULL,
  position = "identity",
  na.rm = FALSE,
  orientation = NA,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...
)

stat_fit_fitted(
  mapping = NULL,
  data = NULL,
  geom = "point",
  method = "lm",
  method.args = list(),
  n.min = 2L,
  formula = NULL,
  position = "identity",
  na.rm = FALSE,
  orientation = NA,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...
)
Arguments

mapping  The aesthetic mapping, usually constructed with `aes`. Only needs to be set at
the layer level if you are overriding the plot defaults.
data  A layer specific dataset - only needed if you want to override the plot defaults.
geom  The geometric object to use display the data
method  function or character If character, "lm", "rlm", "lqs", "rq" and the name of a
function to be matched, possibly followed by the fit function's method argument separated by a colon (e.g. "rq:br"). Functions implementing methods must accept arguments to parameters formula, data, weights and method. A fitted() method must exist for the returned model fit object class.
method.args  named list with additional arguments.
n.min  integer Minimum number of distinct values in the explanatory variable (on the
rhs of formula) for fitting to the attempted.
formula  a "formula" object. Using aesthetic names instead of original variable names.
position  The position adjustment to use for overlapping points on this layer
na.rm  a logical indicating whether NA values should be stripped before the computa-
tion proceeds.
orientation  character Either "x" or "y" controlling the default for formula.
show.legend  logical. Should this layer be included in the legends? NA, the default, includes if
any aesthetics are mapped. FALSE never includes, and TRUE always includes.
inherit.aes  If FALSE, overrides the default aesthetics, rather than combining with them. This
is most useful for helper functions that define both data and aesthetics and should
not inherit behaviour from the default plot specification, e.g. borders.

...  other arguments passed on to layer. This can include aesthetics whose values
you want to set, not map. See layer for more details.

Details

This stat can be used to automatically highlight residuals as segments in a plot of a fitted model
equation. This stat only generates the residuals, the predicted values need to be separately added
to the plot, so to make sure that the same model formula is used in all steps it is best to save the
formula as an object and supply this object as argument to the different statistics.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user,
but instead a data frame with the variables mapped to aesthetics. In other words, it respects the
grammar of graphics and consequently within the model formula names of aesthetics like $x$ and
$y$ should be used instead of the original variable names. This helps ensure that the model is fitted
to the same data as plotted in other layers.

Computed variables

Data frame with same nrow as data as subset for each group containing five numeric variables.

x  x coordinates of observations
x.fitted  x coordinates of fitted values
stat_fit_deviations

y  y coordinates of observations
y.fitted  y coordinates of fitted values

To explore the values returned by this statistic we suggest the use of geom_debug. An example is shown below, where one can also see in addition to the computed values the default mapping of the fitted values to aesthetics xend and yend.

Note

In the case of method = "rq" quantiles are fixed at tau = 0.5 unless method.args has length > 0. Parameter orientation is redundant as it only affects the default for formula but is included for consistency with ggplot2.

stat_fit_glance

One row summary data frame for a fitted model

Description

stat_fit_glance fits a model and returns a "tidy" version of the model's fit, using 'glance()' methods from packages 'broom', 'broom.mixed', or other sources.

Usage

stat_fit_glance(
  mapping = NULL,
  data = NULL,
  geom = "text_npc",
  method = "lm",
  method.args = list(formula = y ~ x),
  n.min = 2L,
  glance.args = list(),
  label.x = "left",
  label.y = "top",
  hstep = 0,
  vstep = 0.075,
  position = "identity",
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...
)

Arguments

mapping
  The aesthetic mapping, usually constructed with aes. Only needs to be set at the layer level if you are overriding the plot defaults.

data
  A layer specific data set - only needed if you want to override the plot defaults.
stat_fit_glance

geom
The geometric object to use display the data

method
character or function.

method.args, glance.args
list of arguments to pass to method and to [generics::glance()], respectively.

n.min
integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.

label.x, label.y
numeric with range 0..1 "normalized parent coordinates" (npc units) or character if using geom_text_npc() or geom_label_npc(). If using geom_text() or geom_label() numeric in native data units. If too short they will be recycled.

hstep, vstep
numeric in npc units, the horizontal and vertical step used between labels for different groups.

position
The position adjustment to use for overlapping points on this layer

na.rm
a logical indicating whether NA values should be stripped before the computation proceeds.

show.legend
logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes
If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.

Details

stat_fit_glance together with stat_fit_tidy and stat_fit_augment, based on package 'broom' can be used with a broad range of model fitting functions as supported at any given time by package 'broom'. In contrast to stat_poly_eq which can generate text or expression labels automatically, for these functions the mapping of aesthetic label needs to be explicitly supplied in the call, and labels built on the fly.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. In other words, it respects the grammar of graphics and consequently within arguments passed through method.args names of aesthetics like $x$ and $y$ should be used instead of the original variable names, while data is automatically passed the data frame. This helps ensure that the model is fitted to the same data as plotted in other layers.

Value

The output of the glance() methods is returned almost as is in the data object, as a data frame. The names of the columns in the returned data are consistent with those returned by method glance() from package 'broom', that will frequently differ from the name of values returned by the print methods corresponding to the fit or test function used. To explore the values returned by this statistic including the name of variables/columns, which vary depending on the model fitting function and model formula we suggest the use of geom_debug. An example is shown below.
Warning!

Not all `glance()` methods are defined in package `broom`. `glance()` specializations for mixed models fits of classes `lme`, `nlme`, `lme4`, and many others are defined in package `broom.mixed`.

Handling of grouping

`stat_fit_glance` applies the function given by method separately to each group of observations, and factors mapped to aesthetics, including x and y, create a separate group for each factor level. Because of this, `stat_fit_glance` is not useful for annotating plots with results from `t.test()`, ANOVA or ANCOVA. In such cases use the `stat_fit_tb()` statistic which applies the model fitting per panel.

Model formula required

The current implementation works only with methods that accept a formula as argument and which have a data parameter through which a data frame can be passed. For example, `lm()` should be used with the formula interface, as the evaluation of x and y needs to be delayed until the internal data object of the ggplot is available. With some methods like `stats::cor.test()` the data embedded in the "ggplot" object cannot be automatically passed as argument for the data parameter of the test or model fit function. Please, for annotations based on `stats::cor.test()` use `stat_correlation()`.

Note

Although arguments passed to parameter `glance.args` will be passed to `[generics::glance()]` whether they are silently ignored or obeyed depends on each specialization of `[glance()]`, so do carefully read the documentation for the version of `[glance()]` corresponding to the `method` used to fit the model.

See Also

`broom` and `broom.mixed` for details on how the tidying of the result of model fits is done.

stat_fit_residuals  Residuals from a model fit

Description

stat_fit_residuals fits a linear model and returns residuals ready to be plotted as points.

Usage

stat_fit_residuals(
  mapping = NULL,
  data = NULL,
  geom = "point",
  method = "lm",
  method.args = list(),
  n.min = 2L,
  formula = NULL,
  resid.type = NULL,
  weighted = FALSE,
  position = "identity",
  na.rm = FALSE,
  orientation = NA,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...
Arguments

- **mapping**: The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
- **data**: A layer specific dataset - only needed if you want to override the plot defaults.
- **geom**: The geometric object to use display the data
- **method**: function or character If character, "lm", "rlm", "rq" and the name of a function to be matched, possibly followed by the fit function's method argument separated by a colon (e.g. "rq:br"). Functions implementing methods must accept arguments to parameters formula, data, weights and method. A `residuals()` method must exist for the returned model fit object class.
- **method.args**: named list with additional arguments.
- **n.min**: integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.
- **formula**: a "formula" object. Using aesthetic names instead of original variable names.
- **resid.type**: character passed to `residuals()` as argument for type (defaults to "working" except if weighted = TRUE when it is forced to "deviance").
- **weighted**: logical If true weighted residuals will be returned.
- **position**: The position adjustment to use for overlapping points on this layer
- **na.rm**: a logical indicating whether NA values should be stripped before the computation proceeds.
- **orientation**: character Either "x" or "y" controlling the default for `formula`.
- **show.legend**: logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
- **inherit.aes**: If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and should not inherit behaviour from the default plot specification, e.g. `borders`.
- **...**: other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.

Details

This stat can be used to automatically plot residuals as points in a plot. At the moment it supports only linear models fitted with function `lm()` or `rlm()`. It applies to the fitted model object methods `residuals` or `weighted.residuals` depending on the argument passed to parameter weighted.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. In other words, it respects the grammar of graphics and consequently within the model `formula` names of aesthetics like $x$ and $y$ should be used instead of the original variable names, while data is automatically passed the data frame. This helps ensure that the model is fitted to the same data as plotted in other layers.

Computed variables

Data frame with same value of `nrow` as data as subset for each group containing five numeric variables.
x  x coordinates of observations or x residuals from fitted values,
y  y coordinates of observations or y residuals from fitted values,
x.resid  residuals from fitted values,
y.resid  residuals from fitted values,
weights  the weights passed as input to lm or those computed by rlm.

For orientation = "x", the default, stat(y.resid) is copied to variable y, while for orientation = "y" stat(x.resid) is copied to variable x.

Note
How weights are applied to residuals depends on the method used to fit the model. For ordinary least squares (OLS), weights are applied to the squares of the residuals, so the weighted residuals are obtained by multiplying the "deviance" residuals by the square root of the weights. When residuals are penalized differently to fit a model, the weighted residuals need to be computed accordingly. Say if we use the absolute value of the residuals instead of the squared values, weighted residuals are obtained by multiplying the residuals by the weights.

stat_fit_tb

Model-fit summary or ANOVA

Description

stat_fit_tb fits a model and returns a "tidy" version of the model’s summary or ANOVA table, using 'tidy()' methods from packages 'broom', 'broom.mixed', or other 'broom' extensions. The annotation is added to the plots in tabular form.

Usage

stat_fit_tb(
  mapping = NULL,
  data = NULL,
  geom = "table_npc",
  method = "lm",
  method.args = list(formula = y ~ x),
  n.min = 2L,
  tidy.args = list(),
  tb.type = "fit.summary",
  tb.vars = NULL,
  tb.params = NULL,
  digits = 3,
  p.digits = digits,
  label.x = "center",
  label.y = "top",
  label.x_npc = NULL,
  label.y_npc = NULL,
  position = "identity",
  table.theme = NULL,
  table.rownames = FALSE,
  table.colnames = TRUE,
  table.hjust = 1,
  parse = FALSE,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...
)
Arguments

- **mapping**: The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
- **data**: A layer specific dataset, only needed if you want to override the plot defaults.
- **geom**: The geometric object to use display the data
- **method**: character.
- **method.args, tidy.args**: lists of arguments to pass to method and to tidy().
- **n.min**: integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.
- **tb.type**: character One of "fit.summary", "fit.anova" or "fit.coefs".
- **tb.vars, tb.params**: character or numeric vectors, optionally named, used to select and/or rename the columns or the parameters in the table returned.
- **digits**: integer indicating the number of significant digits to be used for all numeric values in the table.
- **p.digits**: integer indicating the number of decimal places to round p-values to, with those rounded to zero displayed as the next larger possible value preceded by "<". If p.digits is outside the range 1..22 no rounding takes place.
- **label.x, label.y**: numeric Coordinates (in data units) to be used for absolute positioning of the output. If too short they will be recycled.
- **label.x.npc, label.y.npc**: numeric with range 0..1 or character. Coordinates to be used for positioning the output, expressed in "normalized parent coordinates" or character string. If too short they will be recycled.
- **position**: The position adjustment to use for overlapping points on this layer
- **table.theme**: NULL, list or function A `gridExtra` `theme` definition, or a constructor for a `theme` or NULL for default.
- **table.rownames, table.colnames**: logical flag to enable or disabling printing of row names and column names.
- **table.hjust**: numeric Horizontal justification for the core and column headings of the table.
- **parse**: If TRUE, the labels will be parsed into expressions and displayed as described in `plotmath`.
- **na.rm**: a logical indicating whether NA values should be stripped before the computation proceeds.
- **show.legend**: logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
- **inherit.aes**: If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. `borders`.
- **...**: other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.
Details

`stat_fit_tb()` Applies a model fitting function per panel, using the grouping factors from aesthetic mappings in the fitted model. This is suitable, for example for analysis of variance used to test for differences among groups.

The argument to method can be any fit method for which a suitable `tidy()` method is available, including non-linear regression. Fit methods retain their default arguments unless overridden.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. In other words, it respects the grammar of graphics and consequently within arguments passed through `method.args` names of aesthetics like `x` and `y` should be used instead of the original variable names. The plot’s default data is used by default, which helps ensure that the model is fitted to the same data as plotted in other layers.

Value

A tibble with columns named `fm.tb` (a tibble returned by `tidy()` with possibly renamed and subset columns and rows, within a list), `fm.tb.type` (copy of argument passed to `tb.type`), `fm.class` (the class of the fitted model object), `fm.method` (the fit function’s name), `fm.call` (the call if available), `x` and `y`.

To explore the values returned by this statistic, which vary depending on the model fitting function and model formula we suggest the use of `geom_debug`.

Computed variables

The output of `tidy()` is returned as a single "cell" in a tibble (i.e., a tibble nested within a tibble). The returned data object contains a single tibble, containing the result from a single model fit to all data in a panel. If grouping is present, it is ignored in the sense of returning a single table, but the grouping aesthetic can be a term in the fitted model.

See Also

`broom`, `broom.mixed`, and `tidy` for details on how the tidying of the result of model fits is done. See `geom_table` for details on how inset tables respond to mapped aesthetics and table themes. For details on predefined table themes see `ttheme_gtdefault`.

Other ggplot statistics for model fits: `stat_fit_augment()`, `stat_fit_deviations()`, `stat_fit_glance()`, `stat_fit_residuals()`, `stat_fit_tidy()`

```

stat_fit_tidy

One row data frame with fitted parameter estimates

Description

stat_fit_tidy fits a model and returns a "tidy" version of the model's summary, using ` tidy()`
```
methods from packages 'broom', 'broom.mixed', or other sources. To add the summary in tabular form use `stat_fit_tb` instead of this statistic. When using `stat_fit_tidy()` you will most likely want to change the default mapping for label.

Usage

```r
stat_fit_tidy(
  mapping = NULL,
  data = NULL,
  geom = "text_npc",
  method = "lm",
  method.args = list(formula = y ~ x),
  n.min = 2L,
  tidy.args = list(),
  label.x = "left",
  label.y = "top",
  hstep = 0,
  vstep = NULL,
  sanitize.names = FALSE,
  position = "identity",
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...
)
```

Arguments

- **mapping**: The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
- **data**: A layer specific dataset - only needed if you want to override the plot defaults.
- **geom**: The geometric object to use display the data
- **method**: character or function.
- **method.args, tidy.args**: list of arguments to pass to `method`, and to `generics::tidy`, respectively.
- **n.min**: integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.
- **label.x, label.y**: numeric with range 0..1 or character. Coordinates to be used for positioning the output, expressed in "normalized parent coordinates" or character string. If too short they will be recycled.
- **hstep, vstep**: numeric in npc units, the horizontal and vertical step used between labels for different groups.
- **sanitize.names**: logical If true sanitize column names in the returned data with R’s `make.names()` function.
- **position**: The position adjustment to use for overlapping points on this layer
**Details**

`stat_fit_tidy` together with `stat_fit_glance` and `stat_fit_augment`, based on package 'broom' can be used with a broad range of model fitting functions as supported at any given time by 'broom'. In contrast to `stat_poly_eq` which can generate text or expression labels automatically, for these functions the mapping of aesthetic `label` needs to be explicitly supplied in the call, and labels built on the fly.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. In other words, it respects the grammar of graphics and consequently within arguments passed through method `args` names of aesthetics like `$x$` and `$y$` should be used instead of the original variable names, while data is automatically passed the data frame. This helps ensure that the model is fitted to the same data as plotted in other layers.

**Value**

The output of `tidy()` is returned after reshaping it into a single row. Grouping is respected, and the model fitted separately to each group of data. The returned data object has one row for each group within a panel. To use the intercept, note that output of `tidy()` is renamed from `(Intercept)` to `Intercept`. Otherwise, the names of the columns in the returned data are based on those returned by the `tidy()` method for the model fit class returned by the fit function. These will frequently differ from the name of values returned by the print methods corresponding to the fit or test function used.

To explore the values returned by this statistic including the name of variables/columns, which vary depending on the model fitting function and model formula, we suggest the use of `geom_debug`. An example is shown below. Names of columns as returned by default are not always syntactically valid R names making it necessary to use back ticks to access them. Syntactically valid names are guaranteed if `sanitize.names = TRUE` is added to the call.

To explore the values returned by this statistic, which vary depending on the model fitting function and model formula we suggest the use of `geom_debug`. An example is shown below.

**Warning!**

Not all `glance()` methods are defined in package 'broom'. `glance()` specializations for mixed models fits of classes ‘lme’, ‘nlme’, ‘lme4’, and many others are defined in package 'broom.mixed'.
**Handling of grouping**

`stat_fit_tidy` applies the function given by method separately to each group of observations; in ggplot2 factors mapped to aesthetics generate a separate group for each level. Because of this, `stat_fit_tidy` is not useful for annotating plots with results from `t.test()` or ANOVA or ANCOVA. In such cases use instead `stat_fit_tb()` which applies the model fitting per panel.

**Note**

The statistic `stat_fit_tidy` can be used only with methods that accept formulas under any formal parameter name and a data argument. Use `ggplot2::stat_smooth()` instead of `stat_fit_augment` in production code if the additional features are not needed.

Although arguments passed to parameter `tidy.args` will be passed to `[generics::tidy()]` whether they are silently ignored or obeyed depends on each specialization of `[tidy()]`, so do carefully read the documentation for the version of `[tidy()]` corresponding to the `method` used to fit the model. You will also need to manually install the package, such as `broom`, where the tidier you intend to use are defined.

**See Also**

`broom` and `broom.mixed` for details on how the tidying of the result of model fits is done.

Other `ggplot` statistics for model fits: `stat_fit_augment()`, `stat_fit_deviations()`, `stat_fit_glance()`, `stat_fit_residuals()`, `stat_fit_tb()`

**Examples**

```r
# Package 'broom' needs to be installed to run these examples.
# We check availability before running them to avoid errors.

if (requireNamespace("broom", quietly = TRUE)) {
  broom.installed <- TRUE
  library(broom)
  library(quantreg)

  # Inspecting the returned data using geom_debug()
  if (requireNamespace("gginnards", quietly = TRUE)) {
    library(gginnards)

    # This provides a quick way of finding out the names of the variables that
    # are available for mapping to aesthetics. This is specially important for
    # this stat as these names depend on the specific tidy() method used, which
    # depends on the method used, such as lm(), used to fit the model.

    # Regression by panel, default column names
    ggplot(mtcars, aes(x = disp, y = mpg)) +
      stat_smooth(method = "lm", formula = y ~ x + I(x^2)) +
      geom_point(aes(colour = factor(cyl))) +
      stat_fit_tidy(method = "lm",
                    method.args = list(formula = y ~ x + I(x^2)),
                    geom = "debug")
  }
}
```
# Regression by panel, sanitized column names

```r
ggplot(mtcars, aes(x = disp, y = mpg)) +
  stat_smooth(method = "lm", formula = y ~ x + I(x^2)) +
  geom_point(aes(colour = factor(cyl))) +
  stat_fit_tidy(method = "lm",
    method.args = list(formula = y ~ x + I(x^2)),
    geom = "debug", sanitize.names = TRUE)
```

# Regression by panel example

```r
if (broom.installed)
  ggplot(mtcars, aes(x = disp, y = mpg)) +
  stat_smooth(method = "lm", formula = y ~ x) +
  geom_point(aes(colour = factor(cyl))) +
  stat_fit_tidy(method = "lm",
    label.x = "right",
    method.args = list(formula = y ~ x),
    mapping = aes(label = sprintf("Slope = %.3g
p-value = %.3g",
                       after_stat(x_estimate),
                       after_stat(x_p.value)))))
```

# Regression by group example

```r
if (broom.installed)
  ggplot(mtcars, aes(x = disp, y = mpg, colour = factor(cyl))) +
  stat_smooth(method = "lm", formula = y ~ x) +
  geom_point() +
  stat_fit_tidy(method = "lm",
    label.x = "right",
    method.args = list(formula = y ~ x),
    mapping = aes(label = sprintf("Slope = %.3g, p-value = %.3g",
                                   after_stat(x_estimate),
                                   after_stat(x_p.value)))))
```

# Weighted regression example

```r
if (broom.installed)
  ggplot(mtcars, aes(x = disp, y = mpg, weight = cyl)) +
  stat_smooth(method = "lm", formula = y ~ x) +
  geom_point(aes(colour = factor(cyl))) +
  stat_fit_tidy(method = "lm",
    label.x = "right",
    method.args = list(formula = y ~ x, weights = quote(weight)),
    mapping = aes(label = sprintf("Slope = %.3g\np-value = %.3g",
                                   after_stat(x_estimate),
                                   after_stat(x_p.value)))))
```

# Quantile regression

```r
if (broom.installed)
  ggplot(mtcars, aes(x = disp, y = mpg)) +
  stat_smooth(method = "lm", formula = y ~ x) +
  geom_point() +
  stat_fit_tidy(method = "rq",
    label.y = "bottom",
```
\texttt{stat\_ma\_eq}

\begin{verbatim}
method.args = list(formula = y ~ x),
tidy.args = list(se.type = "nid"),
mapping = aes(label = sprintf("Slope = %.3g\n p-value = %.3g", after_stat(x_estimate),
                          after_stat(x_p.value)))
\end{verbatim}

\section*{Description}

\texttt{stat\_ma\_eq} fits model II regressions. From the fitted model it generates several labels including the equation, p-value, coefficient of determination (R^2), and number of observations.

\section*{Usage}

\begin{verbatim}
stat\_ma\_eq(
    mapping = NULL,
    data = NULL,
    geom = "text_npc",
    position = "identity",
    \ldots,
    formula = NULL,
    method = "Imodel2:MA",
    method.args = list(),
n.min = 2L,
range.y = NULL,
range.x = NULL,
nperm = 99,
eq.with.lhs = TRUE,
eq.x.rhs = NULL,
small.r = FALSE,
small.p = FALSE,
coef.digits = 3,
coef.keep.zeros = TRUE,
rr.digits = 2,
theta.digits = 2,
p.digits = max(1, ceiling(log10(nperm))),
label.x = "left",
label.y = "top",
hstep = 0,
vstep = NULL,
output.type = NULL,
na.rm = FALSE,
orientation = NA,
parse = NULL,
\end{verbatim}
show.legend = FALSE, 
inherit.aes = TRUE
)

Arguments

mapping  The aesthetic mapping, usually constructed with aes. Only needs to be set at
the layer level if you are overriding the plot defaults.
data  A layer specific dataset, only needed if you want to override the plot defaults.
geom  The geometric object to use display the data
position  The position adjustment to use for overlapping points on this layer
...  other arguments passed on to layer. This can include aesthetics whose values
you want to set, not map. See layer for more details.
formula  a formula object. Using aesthetic names x and y instead of original variable
names.
method  function or character If character, "MA", "SMA", "RMA" or "OLS", alternatively "lmol2" or the name of a model fit function are accepted, possibly
followed by the fit function's method argument separated by a colon (e.g.
"lmol2:MA"). If a function different to lmol2(), it must accept arguments
named formula, data, range.y, range.x and nperm and return a model fit
object of class lmol2.
method.args  named list with additional arguments.
n.min  integer Minimum number of distinct values in the explanatory variable (on the
rhs of formula) for fitting to the attempted.
range.y, range.x  character Pass "relative" or "interval" if method "RMA" is to be computed.
nperm  integer Number of permutation used to estimate significance.
eq.with.lhs  If character the string is pasted to the front of the equation label before parsing
or a logical (see note).
eq.x.rhs  character this string will be used as replacement for "x" in the model equation
when generating the label before parsing it.
small.r, small.p  logical Flags to switch use of lower case r and p for coefficient of determination
and p-value.
coef.digits  integer Number of significant digits to use for the fitted coefficients.
coef.keep.zeros  logical Keep or drop trailing zeros when formatting the fitted coefficients and
F-value.
rr.digits, theta.digits, p.digits  integer Number of digits after the decimal point to use for R^2, theta and P-value
in labels. If Inf, use exponential notation with three decimal places.
label.x, label.y  numeric with range 0..1 "normalized parent coordinates" (npc units) or charac-
ter if using geom_text_npc() or geom_label_npc(). If using geom_text() or
geom_label() numeric in native data units. If too short they will be recycled.
stat_ma_eq

hstep, vstep numeric in npc units, the horizontal and vertical step used between labels for different groups.

output.type character One of "expression", "LaTeX", "text", "markdown" or "numeric".

na.rm a logical indicating whether NA values should be stripped before the computation proceeds.

orientation character Either "x" or "y" controlling the default for formula.

parse logical Passed to the geom. If TRUE, the labels will be parsed into expressions and displayed as described in ?plotmath. Default is TRUE if output.type = "expression" and FALSE otherwise.

show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

This stat can be used to automatically annotate a plot with \( R^2 \), \( P \)-value, \( n \) and/or the fitted model equation. It supports linear major axis (MA), standard major axis (SMA) and ranged major axis (RMA) regression by means of function \texttt{lmodel2}. Please see the documentation, including the vignette of package 'lmodel2' for details. The parameters in \texttt{stat_ma_eq()} follow the same naming as in function \texttt{lmodel2()}.

It is important to keep in mind that although the fitted line does not depend on whether the \( x \) or \( y \) appears on the rhs of the model formula, the numeric estimates for the parameters do depend on this.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. \texttt{stat_ma_eq()} mimics how \texttt{stat_smooth()} works, except that only linear regression can be fitted. Similarly to these statistics the model fits respect grouping, so the scales used for \( x \) and \( y \) should both be continuous scales rather than discrete.

The minimum number of observations with distinct values can be set through parameter \( n\_\text{min} \). The default \( n\_\text{min} = 2 \) is the smallest possible value. However, model fits with very few observations are of little interest and using a larger number for \( n\_\text{min} \) than the default is usually wise.

Value

A data frame, with a single row and columns as described under Computed variables. In cases when the number of observations is less than \( n\_\text{min} \) a data frame with no rows or columns is returned rendered as an empty/invisible plot layer.

Aesthetics

\texttt{stat_ma_eq} understands \( x \) and \( y \), to be referenced in the formula while the weight aesthetic is ignored. Both \( x \) and \( y \) must be mapped to numeric variables. In addition, the aesthetics understood by the geom ("text" is the default) are understood and grouping respected.
Transformation of x or y within the model formula is not supported by \texttt{stat_ma_eq()}. In this case, transformations should never be applied in the model formula, but instead in the mapping of the variables within \texttt{aes}.

Computed variables

If output.type different from "numeric" the returned tibble contains columns listed below. If the fitted model does not contain a given value, the label is set to \texttt{character(0L)}.

\begin{itemize}
  \item x.npcx x position
  \item y.npcy y position
  \item eq.label equation for the fitted polynomial as a character string to be parsed
  \item rr.label $R^2$ of the fitted model as a character string to be parsed
  \item p.value.label P-value if available, depends on method.
  \item theta.label Angle in degrees between the two OLS lines for lines estimated from $y \sim x$ and $x \sim y$ linear model (\texttt{lm}) fits.
  \item n.label Number of observations used in the fit.
  \item grp.label Set according to mapping in \texttt{aes}.
  \item method.label Set according method used.
  \item r.squared, theta, p.value, n numeric values, from the model fit object
\end{itemize}

If output.type is "numeric" the returned tibble contains columns listed below. If the model fit function used does not return a value, the variable is set to \texttt{NA_real_}.

\begin{itemize}
  \item x.npcx x position
  \item y.npcy y position
  \item coef.ls list containing the "coefficients" matrix from the summary of the fit object
  \item r.squared, theta, p.value, n numeric values, from the model fit object
  \item grp.label Set according to mapping in \texttt{aes}.
  \item b_0.constant TRUE is polynomial is forced through the origin
  \item b_i One or two columns with the coefficient estimates
\end{itemize}

To explore the computed values returned for a given input we suggest the use of \texttt{geom_debug} as shown in the last examples below.

Note

For backward compatibility a logical is accepted as argument for \texttt{eq.with.lhs}. If \texttt{TRUE}, the default is used, either "x" or "y", depending on the argument passed to \texttt{formula}. However, "x" or "y" can be substituted by providing a suitable replacement character string through \texttt{eq.x.rhs}. Parameter \texttt{orientation} is redundant as it only affects the default for \texttt{formula} but is included for consistency with \texttt{ggplot2::stat_smooth()}. Methods in \texttt{lmodel2} are all computed always except for RMA that requires a numeric argument to at least one of \texttt{range.y} or \texttt{range.x}. The results for specific methods are extracted a posteriori from the model fit object. When a function is passed as argument to \texttt{method}, the method can be passed
in a list to method.args as member method. More easily, the name of the function can be passed as a character string together with the lmodel2-supported method.

R option OutDec is obeyed based on its value at the time the plot is rendered, i.e., displayed or printed. Set options(OutDec = ",") for languages like Spanish or French.

See Also

The major axis regression model is fitted with function lmodel2, please consult its documentation. Statistic stat_ma_eq() can return different ready formatted labels depending on the argument passed to output.type. If ordinary least squares polynomial regression is desired, then stat_poly_eq. If quantile-fitted polynomial regression is desired, stat_quant_eq should be used. For other types of models such as non-linear models, statistics stat_fit_glance and stat_fit_tidy should be used and the code for construction of character strings from numeric values and their mapping to aesthetic label explicitly supplied in the call.

Other ggplot statistics for major axis regression: stat_ma_line()

Examples

# generate artificial data
set.seed(98723)
my.data <- data.frame(x = rnorm(100) + (0:99) / 10 - 5,
y = rnorm(100) + (0:99) / 10 - 5,
group = c("A", "B"))

# using defaults (major axis regression)
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_line() +
  stat_ma_eq()

# use_label() can assemble and map a combined label
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_line(method = "MA") +
  stat_ma_eq(use_label(c("eq", "R2", "P")))

ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_line(method = "MA") +
  stat_ma_eq(use_label(c("R2", "P", "theta", "method")))

# using ranged major axis regression
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_line(method = "RMA",
    range.y = "interval",
    range.x = "interval") +
  stat_ma_eq(use_label(c("eq", "R2", "P")),
    method = "RMA",
    range.y = "interval",
    range.x = "interval")
No permutation-based test

```r
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_line(method = "MA") +
  stat_ma_eq(use_label(c("eq", "R2")),
              method = "MA",
              nperm = 0)
```

Explicit formula "x explained by y"

```r
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_line(formula = x ~ y) +
  stat_ma_eq(formula = x ~ y,
             use_label(c("eq", "R2", "P")))
```

Modifying both variables within aes()

```r
ggplot(my.data, aes(log(x + 10), log(y + 10))) +
  geom_point() +
  stat_poly_line() +
  stat_poly_eq(use_label("eq"),
               eq.x.rhs = "~~log(x+10)",
               eq.with.lhs = "log(y+10)~~ivar\ equivalence\"
```

Grouping

```r
ggplot(my.data, aes(x, y, color = group)) +
  geom_point() +
  stat_ma_line() +
  stat_ma_eq()
```

Labelling equations

```r
ggplot(my.data,
       aes(x, y, shape = group, linetype = group, grp.label = group)) +
  geom_point() +
  stat_ma_line(color = "black") +
  stat_ma_eq(use_label(c("grp", "eq", "R2"))) +
  theme_classic()
```

Inspecting the returned data using geom_debug()

This provides a quick way of finding out the names of the variables that
are available for mapping to aesthetics with after_stat().

```r
if (gginnards.installed)
  library(gginnards)
  ggplot(my.data, aes(x, y)) +
       geom_point() +
       stat_ma_eq(geom = "debug")
```
## Not run:
if (gginnards.installed)
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_eq(aes(label = after_stat(eq.label)),
             geom = "debug",
             output.type = "markdown")

if (gginnards.installed)
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_eq(geom = "debug", output.type = "text")

if (gginnards.installed)
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_ma_eq(geom = "debug", output.type = "numeric")

## End(Not run)

---

**stat_ma_line**

Predicted line from major axis linear fit

### Description

Predicted values and a confidence band are computed and, by default, plotted. `stat_ma_line()` behaves similarly to `stat_smooth` except for fitting the model with `lmodel2::lmodel2()` with "MA" as default for `method`.

### Usage

```r
stat_ma_line(
  mapping = NULL,
  data = NULL,
  geom = "smooth",
  position = "identity",
  ..., 
  method = "lmodel2:MA",
  method.args = list(), 
  n.min = 2L,
  formula = NULL, 
  range.y = NULL, 
  range.x = NULL, 
  se = TRUE, 
  fm.values = FALSE, 
  n = 80, 
  nperm = 99, 
  fullrange = FALSE,
```

Arguments

_mapping_ The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.

data A layer specific dataset, only needed if you want to override the plot defaults.

_geom_ The geometric object to use display the data

_position_ The position adjustment to use for overlapping points on this layer

_method_ function or character If character, "MA", "SMA", "RMA" or "OLS", alternatively "lmodel2" or the name of a model fit function are accepted, possibly followed by the fit function’s method argument separated by a colon (e.g. "lmodel2:MA"). If a function different to `lmodel2()` , it must accept arguments named formula, data, range.y, range.x and nperm and return a model fit object of class lmodel2.

_method.args_ named list with additional arguments.

_n.min_ integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.

_formula_ a formula object. Using aesthetic names x and y instead of original variable names.

_range.y, range.x_ character Pass "relative" or "interval" if method "RMA" is to be computed.

_se_ logical Return confidence interval around smooth? (‘TRUE’ by default, see ‘level’ to control.)

_fm.values_ logical Add R2, p-value and n as columns to returned data? (‘FALSE’ by default.)

_n_ Number of points at which to evaluate smoother.

_nperm_ integer Number of permutation used to estimate significance.

_fullrange_ Should the fit span the full range of the plot, or just the data?

_level_ Level of confidence interval to use (only 0.95 currently).

_na.rm_ a logical indicating whether NA values should be stripped before the computation proceeds.

_orientation_ character Either "x" or "y" controlling the default for formula.

_show.legend_ logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

_inherit.aes_ If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.
Details

This statistic fits major axis ("MA") and other model II regressions with function `lmodel2`. Model II regression is called for when both x and y are subject to random variation and the intention is not to predict y from x by means of the model but rather to study the relationship between two independent variables. A frequent case in biology are allometric relationships among body parts.

As the fitted line is the same whether x or y is on the rhs of the model equation, orientation even if accepted does not have an effect on the fit. In contrast, `geom_smooth` treats each axis differently and can thus have two orientations. The orientation is easy to deduce from the argument passed to `formula`. Thus, `stat_ma_line()` will by default guess which orientation the layer should have. If no argument is passed to `formula`, the orientation can be specified directly passing an argument to the orientation parameter, which can be either "x" or "y". The value gives the axis that is on the rhs of the model equation, "x" being the default orientation. Package ‘ggpmisc’ does not define new geometries matching the new statistics as they are not needed and conceptually transformations of data are expressed as statistics.

The minimum number of observations with distinct values can be set through parameter `n.min`. The default `n.min = 2L` is the smallest possible value. However, model fits with very few observations are of little interest and using a larger number for `n.min` than the default is wise.

Value

The value returned by the statistic is a data frame, that will have `n` rows of predicted values and their confidence limits. Optionally it will also include additional values related to the model fit.

Computed variables

`stat_ma_line()` provides the following variables, some of which depend on the orientation:

- `y *or* x` predicted value
- `ymin *or* xmin` lower pointwise confidence interval around the mean
- `ymax *or* xmax` upper pointwise confidence interval around the mean
- `se` standard error

If `fm.values = TRUE` is passed then columns based on the summary of the model fit are added, with the same value in each row within a group. This is wasteful and disabled by default, but provides a simple and robust approach to achieve effects like colouring or hiding of the model fit line based on P-values, r-squared or the number of observations.

Aesthetics

`stat_ma_line` understands x and y, to be referenced in the `formula`. Both must be mapped to numeric variables. In addition, the aesthetics understood by the `geom` ("geom_smooth" is the default) are understood and grouping respected.

# Smooths are automatically fit to each group (defined by categorical
# aesthetics or the group aesthetic) and for each facet.
```
stat_multcomp

Labels for pairwise multiple comparisons

Description

stat_multcomp fits a linear model by default with stats::lm() but alternatively using other model fit functions. The model is passed to function glht() from package ’multcomp’ to fit Tukey, Dunnet or other pairwise contrasts and generates labels based on adjusted $P$-values.

Usage

stat_multcomp(
  mapping = NULL,
  data = NULL,
  geom = NULL,
  position = "identity",
  ..., 
  formula = NULL,
  method = "lm",
  method.args = list(),
  contrasts = "Tukey",
  p.adjust.method = NULL,
  small.p = FALSE,
  adj.method.tag = 4,
p.digits = 3,
label.type = "bars",
fm.cutoff.p.value = 1,
mc.cutoff.p.value = 1,
mc.critical.p.value = 0.05,
label.y = NULL,
vstep = NULL,
output.type = NULL,
na.rm = FALSE,
orientation = "x",
parse = NULL,
show.legend = FALSE,
inherit.aes = TRUE
)

Arguments

mapping The aesthetic mapping, usually constructed with aes. Only needs to be set at the layer level if you are overriding the plot defaults.
data A layer specific dataset, only needed if you want to override the plot defaults.
geom The geometric object to use to display the data.
position The position adjustment to use for overlapping points on this layer.
... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.
formula a formula object. Using aesthetic names x and y instead of original variable names.
method function or character If character, "lm" (or its equivalent "aov"), "rlm" or the name of a model fit function are accepted, possibly followed by the fit function’s method argument separated by a colon (e.g. "rlm:M"). If a function different to lm(), it must accept as a minimum a model formula through its first parameter, and have formal parameters named data, weights, and method, and return a model fit object accepted by function glht().
method.args named list with additional arguments.
contrasts character vector of length one or a numeric matrix. If character, one of "Tukey" or "Dunnet". If a matrix, one column per level of the factor mapped to x and one row per pairwise contrast.
p.adjust.method character As the argument for parameter type of function adjusted( ) passed as argument to parameter test of summary.glht. Accepted values are "single-step", "Shaffer", "Westfall", "free", "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", "none".
small.p logical If true, use of lower case p instead of capital P as the symbol for P-value in labels.
adj.method.tag numeric, character or function If numeric, the length in characters of the abbreviation of the method used to adjust p-values. A value of zero, adds no label and
a negative value uses as starting point for the abbreviation the word "adjusted". If character its value is used as subscript. If a function, the value used is the value returned by the function when passed `p.adjust.method` as its only argument.

- `p.digits` integer Number of digits after the decimal point to use for $R^2$ and $P$-value in labels.
- `label.type` character One of "bars", "letters" or "LETTERS", selects how the results of the multiple comparisons are displayed. Only "bars" can be used together with `contrasts = "Dunnet"`.
- `fm.cutoff.p.value` numeric [0..1] The $P$-value for the main effect of factor x in the ANOVA test for the fitted model above which no pairwise comparisons are computed or labels generated. Be aware that recent literature tends to recommend to consider which testing approach is relevant to the problem at hand instead of requiring the significance of the main effect before applying multiple comparisons’ tests. The default value is 1, imposing no restrictions.
- `mc.cutoff.p.value` numeric [0..1] The $P$-value for the individual contrasts above which no labelled bars are generated. Default is 1, labelling all pairwise contrasts tested.
- `mc.critical.p.value` numeric The critical $P$-value used for tests when encoded as letters.
- `label.y` numeric vector Values in native data units or if character, one of "top" or "bottom". Recycled if too short and truncated if too long.
- `vstep` numeric in npc units, the vertical displacement step-size used between labels for different contrasts when `label.type = "bars"`.
- `output.type` character One of "expression", "LaTeX", "text", "markdown" or "numeric".
- `na.rm` a logical indicating whether NA values should be stripped before the computation proceeds.
- `orientation` character Either "x" or "y" controlling the default for `formula`. **Support for orientation is not yet implemented but is planned.**
- `parse` logical Passed to the geom. If `TRUE`, the labels will be parsed into expressions and displayed as described in `?plotmath`. Default is TRUE if `output.type = "expression"` and FALSE otherwise.
- `show.legend` logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
- `inherit.aes` If FALSE, overrides the default aesthetics, rather than combining with them.

**Details**

This statistic can be used to automatically annotate a plot with $P$-values for pairwise multiple comparison tests, based on Tukey contrasts (all pairwise), Dunnet contrasts (other levels against the first one) or a subset of all possible pairwise contrasts. See Meier (2022, Chapter 3) for an accessible explanation of multiple comparisons and contrasts with package ‘multcomp’, of which `stat_multcomp()` is mostly a wrapper.
The explanatory variable mapped to the $x$ aesthetic must be a factor as this creates the required grouping. Currently, contrasts that involve more than two levels of a factor, such as the average of two treatment levels against a control level are not supported, mainly because they require a new geometry that I need to design, implement and add to package `ggpp`.

Two ways of displaying the outcomes are implemented, and are selected by `"bars"`, `"letters"` or `"LETTERS"` as argument to parameter `label.type`. `"letters"` and `"LETTERS"` can be used only with Tukey contrasts, as otherwise the encoding is ambiguous. As too many bars clutter a plot, the maximum number of factor levels supported for `"bars"` together with Tukey contrasts is five, while together with Dunnet contrasts or contrasts defined by a numeric matrix, no limit is imposed.

`stat_multcomp()` by default generates character labels ready to be parsed as R expressions but LaTeX (use TikZ device), markdown (use package `ggtext`) and plain text are also supported, as well as numeric values for user-generated text labels. The value of `parse` is set automatically based on `output.type`, but if you assemble labels that need parsing from numeric output, the default needs to be overridden. This statistic only generates annotation labels and segments connecting the compared factor levels, or letter labels that discriminate significantly different groups.

**Value**

A data frame with one row per comparison for `label.type = "bars"`, or a data frame with one row per factor $x$ level for `label.type = "letters"` and for `label.type = "LETTERS"`. Variables (= columns) as described under **Computed variables**.

**Aesthetics**

`stat_multcomp()` understands $x$ and $y$, to be referenced in the formula and weight passed as argument to parameter `weights`. A factor must be mapped to $x$ and numeric variables to $y$, and, if used, to weight. In addition, the aesthetics understood by the geom (`"label_pairwise"` is the default for `label.type = "bars"`, `"text"` is the default for `label.type = "letters"` and for `label.type = "LETTERS"`) are understood and grouping respected.

**Computed variables**

If `output.type = "numeric"` and `label.type = "bars"` the returned tibble contains columns listed below. In all cases if the model fit function used does not return a value, the label is set to character(0L) and the numeric value to NA.

- **x, x.left.tip, x.right.tip** $x$ position, numeric.
- **y** $y$ position, numeric.
- **coefficients** Delta estimate from pairwise contrasts, numeric.
- **contrasts** Contrasts as two levels’ ordinal "numbers" separated by a dash, character.
- **tstat** $t$-statistic estimates for the pairwise contrasts, numeric.
- **p.value** $P$-value for the pairwise contrasts.
- **fm.method** Set according method used.
- **fm.class** Most derived class of the fitted model object.
- **fm.formula** Formula extracted from the fitted model object if available, or the formula argument.
**stat_multcomp**

- `fm.formula.chr` Formula extracted from the fitted model object if available, or the formula argument, formatted as character.
- `mc.adjusted` The method used to adjust the \( P \)-values.
- `mc.contrast` The type of contrast used for multiple comparisons.
- `n` The total number of observations or rows in data.
- `default.label` text label, always included, but possibly NA.

If `output.type` is not "numeric" the returned data frame includes in addition the following labels:

- `stars.label` \( P \)-value for the pairwise contrasts encoded as "starts", character.
- `p.value.label` \( P \)-value for the pairwise contrasts, character.
- `delta.label` The coefficient or estimate for the difference between compared pairs of levels.
- `t.value.label` \( t \)-statistic estimates for the pairwise contrasts, character.

If `label.type = "letters"` or `label.type = "LETTERS"` the returned tibble contains columns listed below.

- `x.left.tip, x.right.tip` x position, numeric.
- `y` y position, numeric.
- `critical.p.value` \( P \)-value used in pairwise tests, numeric.
- `fm.method` Set according method used.
- `fm.class` Most derived class of the fitted model object.
- `fm.formula` Formula extracted from the fitted model object if available, or the formula argument.
- `fm.formula.chr` Formula extracted from the fitted model object if available, or the formula argument, formatted as character.
- `mc.adjusted` The method used to adjust the \( P \)-values.
- `mc.contrast` The type of contrast used for multiple comparisons.
- `n` The total number of observations or rows in data.
- `default.label` text label, always included, but possibly NA.

If `output.type` is not "numeric" the returned data frame includes in addition the following labels:

- `letters.label` Letters that distinguish levels based on significance from multiple comparisons test.

**Alternatives**

- `stat_signif()` in package `ggsignif` is an earlier and independent implementation of pairwise tests.

**Note**

R option `OutDec` is obeyed based on its value at the time the plot is rendered, i.e., displayed or printed. Set `options(OutDec = ",")` for languages like Spanish or French.

                geom = "debug")

stat_peaks

Local maxima (peaks) or minima (valleys)

Description

stat_peaks finds at which x positions local y maxima are located and
stat_valleys finds at which x positions local y minima are located. Both
stats return a subset of data with rows matching for peaks or valleys
with formatted character labels added. The formatting is determined by a
format string compatible with sprintf() or strftime().

Usage

stat_peaks(
  mapping = NULL,
  data = NULL,
  geom = "point",
  span = 5,
  ignore_threshold = 0,
  strict = FALSE,
  label.fmt = NULL,
  x.label.fmt = NULL,
  y.label.fmt = NULL,
  orientation = "x",
  position = "identity",
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...)
stat_peaks

)

stat_valleys(
    mapping = NULL,
    data = NULL,
    geom = "point",
    span = 5,
    ignore_threshold = 0,
    strict = FALSE,
    label.fmt = NULL,
    x.label.fmt = NULL,
    y.label.fmt = NULL,
    orientation = "x",
    position = "identity",
    na.rm = FALSE,
    show.legend = FALSE,
    inherit.aes = TRUE,
    ...
)

Arguments

mapping  The aesthetic mapping, usually constructed with aes. Only needs to be set at
          the layer level if you are overriding the plot defaults.

data      A layer specific dataset - only needed if you want to override the plot defaults.

data      The geometric object to use display the data.

span      a peak is defined as an element in a sequence which is greater than all other
          elements within a window of width span centered at that element. The default
          value is 5, meaning that a peak is bigger than two consecutive neighbors on each
          side. A NULL value for span is taken as a span covering the whole of the data
          range.

ignore_threshold
          numeric value between 0.0 and 1.0 indicating the size threshold below which
          peaks will be ignored.

strict    logical flag: if TRUE, an element must be strictly greater than all other values
          in its window to be considered a peak. Default: FALSE.

label.fmt character string giving a format definition for converting values into character
          strings by means of function sprintf or strptime, its use is deprecated.

x.label.fmt character string giving a format definition for converting $x$-values into char-
          acter strings by means of function sprintf or strftime. The default argument
          varies depending on the scale in use.

y.label.fmt character string giving a format definition for converting $y$-values into char-
          acter strings by means of function sprintf.

orientation character Either "x" or "y".

position The position adjustment to use for overlapping points on this layer.
na.rm  
a logical value indicating whether NA values should be stripped before the computation proceeds.

show.legend  
logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes  
If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

...  
other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.

Details

These stats use geom_point by default as it is the geom most likely to work well in almost any situation without need of tweaking. The default aesthetics set by these stats allow their direct use with geom_text, geom_label, geom_line, geom_rug, geom_hline and geom_vline. The formatting of the labels returned can be controlled by the user.

The default for parameter strict is TRUE in functions splus2R::peaks() and find_peaks(), while the default is FALSE in stat_peaks() and in stat_valleys().

Returned and computed variables

x  x-value at the peak (or valley) as numeric

y  y-value at the peak (or valley) as numeric

x.label  x-value at the peak (or valley) as character

y.label  y-value at the peak (or valley) as character

Warning!

The current version of these statistics do not support passing nudge_x or nudge_y named parameters to the geometry. Use ‘position’ and one of the position functions such as position_nudge_keep instead.

Note

These statistics check the scale of the x aesthetic and if it is Date or Datetime they correctly generate the labels by transforming the numeric x values to Date or POSIXct objects, respectively. In which case the x.label.fmt must follow the syntax supported by strftime() rather than by sprintf(). Overlap of labels with points can avoided by use of one of the nudge positions, possibly together with geometry geom_text_s from package ggpp, or with geom_text_repel or geom_label_repel from package ggrepel. To discard overlapping labels use check_overlap = TRUE as argument to geom_text or geom_text_s. By default the labels are character values suitable to be plotted as is, but with a suitable format passed as argument to label.fmt labels suitable for parsing by the geoms (e.g. into expressions containing Greek letters, super- or subscripts, maths symbols or maths constructs) can be also easily obtained.
Examples

# lynx is a time.series object
lynx_num.df <-
  try_tibble(lynx,
    col.names = c("year", "lynx"),
    as.numeric = TRUE) # years -> as numeric

ggplot(lynx_num.df, aes(year, lynx)) +
  geom_line() +
  stat_peaks(colour = "red") +
  stat_valleys(colour = "blue")

ggplot(lynx_num.df, aes(lynx, year)) +
  geom_line(orientation = "y") +
  stat_peaks(colour = "red", orientation = "y") +
  stat_valleys(colour = "blue", orientation = "y")

  geom_line() +
  stat_peaks(colour = "red") +
  stat_peaks(colour = "red", geom = "rug")

ggplot(lynx_num.df, aes(year, lynx)) +
  geom_line() +
  stat_peaks(colour = "red") +
  stat_peaks(colour = "red", geom = "text", hjust = -0.1, angle = 33)

ggplot(lynx_num.df, aes(lynx, year)) +
  geom_line(orientation = "y") +
  stat_peaks(colour = "red", orientation = "y") +
  stat_peaks(colour = "red", orientation = "y",
    geom = "text", hjust = -0.1)

lynx_datetime.df <-
  try_tibble(lynx,
    col.names = c("year", "lynx")) # years -> POSIXct

ggplot(lynx_datetime.df, aes(year, lynx)) +
  geom_line() +
  stat_peaks(colour = "red") +
  stat_valleys(colour = "blue")

ggplot(lynx_datetime.df, aes(year, lynx)) +
  geom_line() +
  stat_peaks(colour = "red") +
  stat_peaks(colour = "red",
    geom = "text",
    hjust = -0.1,
    x.label.fmt = "%Y",
    angle = 33)

ggplot(lynx_datetime.df, aes(year, lynx)) +
  geom_line() +
  stat_peaks(colour = "red") +
  stat_peaks(colour = "red",
    geom = "text",
    hjust = -0.1,
    x.label.fmt = "%Y",
    angle = 33)
stat_poly_eq

Equation, p-value, R^2, AIC and BIC of fitted polynomial

Description

stat_poly_eq fits a polynomial by default with stats::lm() but alternatively using robust regression. From the fitted model it generates several labels including the equation, p-value, F-value, coefficient of determination (R^2), 'AIC', 'BIC', and number of observations.

Usage

stat_poly_eq(
  mapping = NULL,
  data = NULL,
  geom = "text_npc",
  position = "identity",
  ..., 
  formula = NULL,
  method = "lm",
  method.args = list(),
  n.min = 2L,
  eq.with.lhs = TRUE,
  eq.x.rhs = NULL,
  small.r = FALSE,
  small.p = FALSE,
  CI.brackets = c("[", "]"),
  rsquared.conf.level = 0.95,
Arguments

**mapping**  
The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.

**data**  
A layer specific dataset, only needed if you want to override the plot defaults.

**geom**  
The geometric object to use display the data

**position**  
The position adjustment to use for overlapping points on this layer

**formula**  
a formula object. Using aesthetic names x and y instead of original variable names.

**method**  
function or character If character, "lm", "rlm" or the name of a model fit function are accepted, possibly followed by the fit function's method argument separated by a colon (e.g. "rlm:method"). If a function different to `lm()`, it must accept as a minimum a model formula through its first parameter, and have formal parameters named data, weights, and method, and return a model fit object of class `lm`.

**method.args**  
named list with additional arguments.

**n.min**  
integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.

**eq.with.lhs**  
If character the string is pasted to the front of the equation label before parsing or a logical (see note).

**eq.x.rhs**  
character this string will be used as replacement for "x" in the model equation when generating the label before parsing it.

**small.r, small.p**  
logical Flags to switch use of lower case r and p for coefficient of determination and p-value.
CI.brackets character vector of length 2. The opening and closing brackets used for the CI label.

rsquared.conf.level numeric Confidence level for the returned confidence interval. Set to NA to skip CI computation.

coeff.digits, f.digits integer Number of significant digits to use for the fitted coefficients and F-value.

coeff.keep.zeros logical Keep or drop trailing zeros when formatting the fitted coefficients and F-value.

rr.digits, p.digits integer Number of digits after the decimal point to use for $R^2$ and P-value in labels. If Inf, use exponential notation with three decimal places.

label.x, label.y numeric with range 0..1 "normalized parent coordinates" (npc units) or character if using geom_text_npc() or geom_label_npc(). If using geom_text() or geom_label() numeric in native data units. If too short they will be recycled.

label.x npc, label.y npc numeric with range 0..1 (npc units) DEPRECATED, use label.x and label.y instead; together with a geom using npcx and npcy aesthetics.

hstep, vstep numeric in npc units, the horizontal and vertical step used between labels for different groups.

output.type character One of "expression", "LaTeX", "text", "markdown" or "numeric".

na.rm a logical indicating whether NA values should be stripped before the computation proceeds.

orientation character Either "x" or "y" controlling the default for formula.

parse logical Passed to the geom. If TRUE, the labels will be parsed into expressions and displayed as described in ?plotmath. Default is TRUE if output.type = "expression" and FALSE otherwise.

show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

This statistic can be used to automatically annotate a plot with $R^2$, adjusted $R^2$ or the fitted model equation. It supports linear regression, robust linear regression and median regression fitted with functions lm, or rlm. The $R^2$ and adjusted $R^2$ annotations can be used with any linear model formula. The confidence interval for $R^2$ is computed with function ci_rsquared from package 'confintr'. The fitted equation label is correctly generated for polynomials or quasi-polynomials through the origin. Model formulas can use poly() or be defined algebraically with terms of powers of increasing magnitude with no missing intermediate terms, except possibly for the intercept indicated by "- 1" or "-1" or "+ 0" in the formula. The validity of the formula is not checked in
the current implementation, and for this reason the default aesthetics sets $R^2$ as label for the annotation. This statistic generates labels as R expressions by default but LaTeX (use TikZ device), markdown (use package ‘ggtext’) and plain text are also supported, as well as numeric values for user-generated text labels. The value of parse is set automatically based on output-type, but if you assemble labels that need parsing from numeric output, the default needs to be overridden. This stat only generates annotation labels, the predicted values/line need to be added to the plot as a separate layer using `stat_poly_line` (or `stat_smooth`), if the default formula is overridden with an argument, it is crucial to make sure that the same model formula is used in all layers. In this case it is best to save the formula as an object and supply this object as argument to the different statistics.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. `stat_poly_eq()` mimics how `stat_smooth()` works, except that only polynomials can be fitted. Similarly to these statistics the model fits respect grouping, so the scales used for x and y should both be continuous scales rather than discrete.

With method "lm", singularity results in terms being dropped with a message if more numerous than can be fitted with a singular (exact) fit. In this case or if the model results in a perfect fit due to a low number of observations, estimates for various parameters are NaN or NA. When this is the case the corresponding labels are set to character(0L) and thus not visible in the plot.

With methods other than "lm", the model fit functions simply fail in case of singularity, e.g., singular fits are not implemented in "rlm".

In both cases the minimum number of observations with distinct values in the explanatory variable can be set through parameter n.min. The default n.min = 2L is the smallest suitable for method "lm" but too small for method "rlm" for which n.min = 3L is needed. Anyway, model fits with very few observations are of little interest and using larger values of n.min than the default is usually wise.

Value

A data frame, with a single row and columns as described under Computed variables. In cases when the number of observations is less than n.min a data frame with no rows or columns is returned rendered as an empty/invisible plot layer.

Aesthetics

`stat_poly_eq()` understands x and y, to be referenced in the formula and weight passed as argument to parameter weights. All three must be mapped to numeric variables. In addition, the aesthetics understood by the geom ("text" is the default) are understood and grouping respected.

If the model formula includes a transformation of x, a matching argument should be passed to parameter eq.x.rhs as its default value "x" will not reflect the applied transformation. In plots, transformation should never be applied to the left hand side of the model formula, but instead in the mapping of the variable within `aes`, as otherwise plotted observations and fitted curve will not match. In this case it may be necessary to also pass a matching argument to parameter eq.with.lhs.

Computed variables

If output.type different from "numeric" the returned tibble contains columns listed below. If the model fit function used does not return a value, the label is set to character(0L).
\textbf{x.npcx} x position
\textbf{y.npcy} y position
\textbf{eq.label} equation for the fitted polynomial as a character string to be parsed
\textbf{rr.label} $R^2$ of the fitted model as a character string to be parsed
\textbf{adj.rr.label} Adjusted $R^2$ of the fitted model as a character string to be parsed
\textbf{rr.confint.label} Confidence interval for $R^2$ of the fitted model as a character string to be parsed
\textbf{f.value.label} F value and degrees of freedom for the fitted model as a whole.
\textbf{p.value.label} P-value for the F-value above.
\textbf{AIC.label} AIC for the fitted model.
\textbf{BIC.label} BIC for the fitted model.
\textbf{n.label} Number of observations used in the fit.
\textbf{grp.label} Set according to mapping in \texttt{aes}.
\textbf{method.label} Set according method used.
\textbf{r.squared, adj.r.squared, p.value, n} numeric values, from the model fit object

If output.type is "numeric" the returned tibble contains columns listed below. If the model fit function used does not return a value, the variable is set to NA\_real\_.

\textbf{x.npcx} x position
\textbf{y.npcy} y position
\textbf{coef.ls} list containing the "coefficients" matrix from the summary of the fit object
\textbf{r.squared, rr.confint.level, rr.confint.low, rr.confint.high, adj.r.squared, f.value, f.df1, f.df2, p.value, AIC, BIC, n} numeric values, from the model fit object
\textbf{grp.label} Set according to mapping in \texttt{aes}.
\textbf{b_0.constant} TRUE is polynomial is forced through the origin
\textbf{b_i} One or columns with the coefficient estimates

To explore the computed values returned for a given input we suggest the use of \texttt{geom_debug} as shown in the last examples below.

\textbf{Alternatives}

\texttt{stat_regline_equation()} in package 'ggpubr' is a renamed but almost unchanged copy of \texttt{stat_poly_eq()} taken from an old version of this package (without acknowledgement of source and authorship). \texttt{stat_regline_equation()} lacks important functionality and contains bugs that have been fixed in \texttt{stat_poly_eq()}.

\textbf{Note}

For backward compatibility a logical is accepted as argument for \texttt{eq.with.lhs}. If TRUE, the default is used, either "x" or "y", depending on the argument passed to \texttt{formula}. However, "x" or "y" can be substituted by providing a suitable replacement character string through \texttt{eq.x.rhs}. Parameter orientation is redundant as it only affects the default for \texttt{formula} but is included for consistency with \texttt{ggplot2::stat_smooth()}.

R option \texttt{OutDec} is obeyed based on its value at the time the plot is rendered, i.e., displayed or printed. Set \texttt{options(OutDec = ",", "}) for languages like Spanish or French.

See Also

This statistics fits a model with function `lm`, function `rlm` or a user supplied function returning an object of class "lm". Consult the documentation of these functions for the details and additional arguments that can be passed to them by name through parameter `method.args`.

This `stat_poly_eq` statistic can return ready formatted labels depending on the argument passed to `output.type`. This is possible because only polynomial and quasy-polynomial models are supported. For quantile regression `stat_quant_eq` should be used instead of `stat_poly_eq` while for model II or major axis regression `stat_ma_eq` should be used. For other types of models such as non-linear models, statistics `stat_fit_glance` and `stat_fit_tidy` should be used and the code for construction of character strings from numeric values and their mapping to aesthetic label needs to be explicitly supplied by the user.

Other `ggplot` statistics for linear and polynomial regression: `stat_poly_line()`

Examples

```r
# generate artificial data
set.seed(4321)

**stat_poly_line**  
*Predicted line from linear model fit*

**Description**

Predicted values and a confidence band are computed and, by default, plotted.

**Usage**

```r
stat_poly_line(
  mapping = NULL,
  data = NULL,
```
geom = "smooth",
position = "identity",
...
method = "lm",
formula = NULL,
se = TRUE,
fm.values = FALSE,
n = 80,
fullrange = FALSE,
level = 0.95,
method.args = list(),
n.min = 2L,
na.rm = FALSE,
orientation = NA,
show.legend = NA,
inherit.aes = TRUE
)

Arguments

mapping The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
data A layer specific dataset, only needed if you want to override the plot defaults.
geom The geometric object to use display the data
position The position adjustment to use for overlapping points on this layer
... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.
method function or character If character, "lm", "rlm" or the name of a model fit function are accepted, possibly followed by the fit function’s method argument separated by a colon (e.g. "rlm:M"). If a function different to `lm()`, it must accept arguments named `formula`, `data`, `weights`, and `method` and return a model fit object of class `lm`.
formula a formula object. Using aesthetic names `x` and `y` instead of original variable names.
se Display confidence interval around smooth? (‘TRUE’ by default, see ‘level’ to control.)
fm.values logical Add R2, adjusted R2, p-value and n as columns to returned data? (‘FALSE’ by default.)
n Number of points at which to evaluate smoother.
fullrange Should the fit span the full range of the plot, or just the data?
level Level of confidence interval to use (0.95 by default).
method.args named list with additional arguments.
n.min integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.
Details

This statistic is similar to `stat_smooth` but has different defaults. It interprets the argument passed to `formula` differently, accepting `y` as explanatory variable and setting `orientation` automatically. The default for `method` is "lm" and spline-based smoothers like `loess` are not supported. Other defaults are consistent with those in `stat_poly_eq()`, `stat_quant_line()`, `stat_quant_eq()`, `stat_ma_line()`, `stat_ma_eq()`.

treats the x and y aesthetics differently and can thus have two orientations. The orientation can be deduced from the argument passed to `formula`. Thus, `stat_poly_line()` will by default guess which orientation the layer should have. If no argument is passed to `formula`, the formula defaults to `y ~ x`. For consistency with `stat_smooth` orientation can be also specified directly passing an argument to the `orientation` parameter, which can be either "x" or "y". The value of `orientation` gives the axis that is taken as the explanatory variable or `x` in the model formula. Package 'ggpmisc' does not define new geometries matching the new statistics as they are not needed and conceptually transformations of `data` are statistics in the grammar of graphics.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. `stat_poly_eq()` mimics how `stat_smooth()` works, except that only polynomials can be fitted. Similarly to these statistics the model fits respect grouping, so the scales used for `x` and `y` should both be continuous scales rather than discrete.

With method "lm", singularity results in terms being dropped with a message if more numerous than can be fitted with a singular (exact) fit. In this case and if the model results in a perfect fit due to low number of observation, estimates for various parameters are NaN or NA.

With methods other than "lm", the model fit functions simply fail in case of singularity, e.g., singular fits are not implemented in "rlm".

In both cases the minimum number of observations with distinct values in the explanatory variable can be set through parameter `n.min`. The default `n.min = 2L` is the smallest suitable for method "lm" but too small for method "rlm" for which `n.min = 3L` is needed. Anyway, model fits with very few observations are of little interest and using larger values of `n.min` than the default is wise.

Value

The value returned by the statistic is a data frame, with `n` rows of predicted values and their confidence limits. Optionally it will also include additional values related to the model fit.

Computed variables

`'stat_poly_line()' provides the following variables, some of which depend on the orientation:
y *or* x  predicted value
ymin *or* xmin  lower pointwise confidence interval around the mean
ymax *or* xmax  upper pointwise confidence interval around the mean
se  standard error

If `fm.values = TRUE` is passed then columns based on the summary of the model fit are added, with the same value in each row within a group. This is wasteful and disabled by default, but provides a simple and robust approach to achieve effects like colouring or hiding of the model fit line based on P-values, r-squared, adjusted r-squared or the number of observations.

Aesthetics

`stat_poly_line` understands `x` and `y`, to be referenced in the formula and weight passed as argument to parameter weights. All three must be mapped to numeric variables. In addition, the aesthetics understood by the geom ("geom_smooth" is the default) are understood and grouping respected.

**stat_quant_band**

*Predicted band from quantile regression fits*

### Description

Predicted values are computed and, by default, plotted as a band plus an optional line within. `stat_quant_band()` supports the use of both \(x\) and \(y\) as explanatory variable in the model formula.

### Usage

```r
stat_quant_band(
  mapping = NULL,
  data = NULL,
  geom = "smooth",
  position = "identity",
  ...,  
  quantiles = c(0.25, 0.5, 0.75),
  formula = NULL,
  fm.values = FALSE,
  n = 80,
  method = "rq",
  method.args = list(),
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)
```
Arguments

mapping The aesthetic mapping, usually constructed with \texttt{aes}. Only needs to be set at the layer level if you are overriding the plot defaults.
data A layer specific dataset, only needed if you want to override the plot defaults.
geom The geometric object to use display the data.
position The position adjustment to use for overlapping points on this layer.
... other arguments passed on to \texttt{layer}. This can include aesthetics whose values you want to set, not map. See \texttt{layer} for more details.
quantiles numeric vector Two or three values in 0..1 indicating the quantiles at the edges of the band and optionally a line within the band.
formula a formula object. Using aesthetic names \texttt{x} and \texttt{y} instead of original variable names.
fm.values logical Add \( n \) as a column to returned data? (\texttt{FALSE} by default.)
n Number of points at which to evaluate smoother.
method function or character If character, "rq", "rqss" or the name of a model fit function are accepted, possibly followed by the fit function's \texttt{method} argument separated by a colon (e.g. "rq:br"). If a function different to \texttt{rq()}, it must accept arguments named \texttt{formula}, \texttt{data}, \texttt{weights}, \texttt{tau} and \texttt{method} and return a model fit object of class \texttt{rq}, \texttt{rqs} or \texttt{rqss}.
method.args named list with additional arguments.
na.rm a logical indicating whether NA values should be stripped before the computation proceeds.
orientation character Either "x" or "y" controlling the default for \texttt{formula}.
show.legend logical. Should this layer be included in the legends? \texttt{NA}, the default, includes if any aesthetics are mapped. \texttt{FALSE} never includes, and \texttt{TRUE} always includes.
inherit.aes If \texttt{FALSE}, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. \texttt{borders}.

Details

This statistic is similar to \texttt{stat_quant_line} but plots the quantiles differently with the band representing a region between two quantiles, while in \texttt{stat_quant_line()} the bands plotted when \texttt{se = TRUE} represent confidence intervals for the fitted quantile lines.

\texttt{geom_smooth}, which is used by default, treats each axis differently and thus is dependent on orientation. If no argument is passed to \texttt{formula}, it defaults to \texttt{y ~ x} but \texttt{x ~ y} is also accepted, and equivalent to \texttt{y ~ x} plus \texttt{orientation = "y"}. Package 'ggpmisc' does not define a new geometry matching this statistic as it is enough for the statistic to return suitable 'x' and 'y' values.

Value

The value returned by the statistic is a data frame, that will have \( n \) rows of predicted values for three quantiles as \texttt{y}, \texttt{ymin} and \texttt{ymax}, plus \texttt{x}. 
Aesthetics

`stat_quant_eq` expects `x` and `y`, aesthetics to be used in the formula rather than the names of the variables mapped to them. If present, the variable mapped to the weight aesthetics is passed as argument to parameter `weights` of the fitting function. All three must be mapped to numeric variables. In addition, the aesthetics recognized by the geometry ("geom_smooth" is the default) are obeyed and grouping respected.

Examples

```r
ggplot(mpg, aes(displ, hwy)) + 
  geom_point() + 
  stat_quant_band()

# If you need the fitting to be done along the y-axis set the orientation
ggplot(mpg, aes(displ, hwy)) + 
  geom_point() + 
  stat_quant_band(orientation = "y")

ggplot(mpg, aes(displ, hwy)) + 
  geom_point() + 
  stat_quant_band(formula = y ~ x)

ggplot(mpg, aes(displ, hwy)) + 
  geom_point() + 
  stat_quant_band(formula = x ~ y)

ggplot(mpg, aes(displ, hwy)) + 
  geom_point() + 
  stat_quant_band(formula = y ~ poly(x, 3))

ggplot(mpg, aes(displ, hwy)) + 
  geom_point() + 
  stat_quant_band(formula = x ~ poly(y, 3))

# Instead of rq() we can use rqss() to fit an additive model:
ggplot(mpg, aes(displ, hwy)) + 
  geom_point() + 
  stat_quant_band(method = "rqss", 
                  formula = y ~ qss(x))

ggplot(mpg, aes(displ, hwy)) + 
  geom_point() + 
  stat_quant_band(method = "rqss", 
                  formula = x ~ qss(y, constraint = "D"))

# Regressions are automatically fit to each group (defined by categorical
# aesthetics or the group aesthetic) and for each facet.
stat_quant_eq

Equation, rho, AIC and BIC from quantile regression

Description

stat_quant_eq fits a polynomial model by quantile regression and generates several labels including the equation, rho, 'AIC' and 'BIC'.

Usage

stat_quant_eq(
  mapping = NULL,
  data = NULL,
  geom = "text_npc",
  formula = y ~ x,
position = "identity",
...
formula = NULL,
quantiles = c(0.25, 0.5, 0.75),
method = "rq:br",
method.args = list(),
n.min = 3L,
eq.with.lhs = TRUE,
eq.x.rhs = NULL,
coef.digits = 3,
coef.keep.zeros = TRUE,
rho.digits = 2,
label.x = "left",
label.y = "top",
label.x.npc = NULL,
label.y.npc = NULL,
hstep = 0,
vstep = NULL,
output.type = "expression",
na.rm = FALSE,
orientation = NA,
parse = NULL,
show.legend = FALSE,
inherit.aes = TRUE
)

Arguments

mapping The aesthetic mapping, usually constructed with aes. Only needs to be set at the layer level if you are overriding the plot defaults.
data A layer specific dataset, only needed if you want to override the plot defaults.
geom The geometric object to use display the data
position The position adjustment to use for overlapping points on this layer
... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.
formula a formula object. Using aesthetic names instead of original variable names.
quantiles numeric vector Values in 0..1 indicating the quantiles.
method function or character If character, "rq" or the name of a model fit function are accepted, possibly followed by the fit function’s method argument separated by a colon (e.g. "rq:br"). If a function different to rq(), it must accept arguments named formula, data, weights, tau and method and return a model fit object of class rq or rqs.
method.args named list with additional arguments passed to rq() or to a function passed as argument to method.
n.min integer Minimum number of observations needed for fitting a the model.
eq.with.lhs  If character the string is pasted to the front of the equation label before parsing or a logical (see note).

eq.x.rhs  character this string will be used as replacement for "x" in the model equation when generating the label before parsing it.

coeff.digits, rho.digits  integer Number of significant digits to use for the fitted coefficients and rho in labels.

coeff.keep.zeros  logical Keep or drop trailing zeros when formatting the fitted coefficients and F-value.

label.x, label.y  numeric with range 0..1 "normalized parent coordinates" (npc units) or character if using geom_text_npc() or geom_label_npc(). If using geom_text() or geom_label() numeric in native data units. If too short they will be recycled.

label.x.npc, label.y.npc  numeric with range 0..1 (npc units) DEPRECATED, use label.x and label.y instead; together with a geom using npcx and npcy aesthetics.

hstep, vstep  numeric in npc units, the horizontal and vertical step used between labels for different groups.

output.type  character One of "expression", "LaTeX", "text", "markdown" or "numeric". In most cases, instead of using this statistic to obtain numeric values, it is better to use stat_fit_tidy().

na.rm  a logical indicating whether NA values should be stripped before the computation proceeds.

orientation  character Either "x" or "y" controlling the default for formula.

parse  logical Passed to the geom. If TRUE, the labels will be parsed into expressions and displayed as described in ?plotmath. Default is TRUE if output.type = "expression" and FALSE otherwise.

show.legend  logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes  If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

This statistic interprets the argument passed to formula differently than stat_quantile accepting y as well as x as explanatory variable, matching stat_quant_line().

When two variables are subject to mutual constrains, it is useful to consider both of them as explanatory and interpret the relationship based on them. So, from version 0.4.1 'ggpmisc' makes it possible to easily implement the approach described by Cardoso (2019) under the name of "Double quantile regression".

This stat can be used to automatically annotate a plot with rho or the fitted model equation. The model fitting is done using package 'quantreg', please, consult its documentation for the details. It supports only linear models fitted with function rq(), passing method = "br" to it, should work well
with up to several thousand observations. The rho, AIC, BIC and n annotations can be used with any linear model formula. The fitted equation label is correctly generated for polynomials or quasi-polynomials through the origin. Model formulas can use `poly()` or be defined algebraically with terms of powers of increasing magnitude with no missing intermediate terms, except possibly for the intercept indicated by "-1" or "-1" or "+0" in the formula. The validity of the formula is not checked in the current implementation. The default aesthetics sets rho as label for the annotation. This stat generates labels as R expressions by default but LaTeX (use TikZ device), markdown (use package 'ggtext') and plain text are also supported, as well as numeric values for user-generated text labels. The value of parse is set automatically based on output-type, but if you assemble labels that need parsing from numeric output, the default needs to be overridden. This stat only generates annotation labels, the predicted values/line need to be added to the plot as a separate layer using `stat_quant_line`, `stat_quant_band` or `stat_quantile`, so to make sure that the same model formula is used in all steps it is best to save the formula as an object and supply this object as argument to the different statistics.

A ggplot statistic receives as data a data frame that is not the one passed as argument by the user, but instead a data frame with the variables mapped to aesthetics. `stat_quant_eq()` mimics how `stat_smooth()` works, except that only polynomials can be fitted. In other words, it respects the grammar of graphics. This helps ensure that the model is fitted to the same data as plotted in other layers.

Function `rq` does not support singular fits, in contrast to `lm`.

The minimum number of observations with distinct values in the explanatory variable can be set through parameter `n.min`. The default `n.min = 3L` is the smallest usable value. However, model fits with very few observations are of little interest and using larger values of `n.min` than the default is usually wise.

Value

A data frame, with one row per quantile and columns as described under **Computed variables**. In cases when the number of observations is less than `n.min` a data frame with no rows or columns is returned rendered as an empty/invisible plot layer.

Aesthetics

`stat_quant_eq()` understands `x` and `y`, to be referenced in the formula and weight passed as argument to parameter `weights` of `rq()`. All three must be mapped to numeric variables. In addition, the aesthetics understood by the geom used ("text" by default) are understood and grouping respected.

If the model formula includes a transformation of `x`, a matching argument should be passed to parameter `eq.x.rhs` as its default value "x" will not reflect the applied transformation. In plots, transformation should never be applied to the left hand side of the model formula, but instead in the mapping of the variable within `aes`, as otherwise plotted observations and fitted curve will not match. In this case it may be necessary to also pass a matching argument to parameter `eq.with.lhs`.

Computed variables

If output.type different from "numeric" the returned tibble contains columns below in addition to a modified version of the original group:
\texttt{x.npcx}  x position
\texttt{y.npcy}  y position
\texttt{eq.label}  equation for the fitted polynomial as a character string to be parsed
\texttt{r.label, and one of cor.label, rho.label, or tau.label}  \texttt{rho} of the fitted model as a character string to be parsed
\texttt{AIC.label}  AIC for the fitted model.
\texttt{n.label}  Number of observations used in the fit.
\texttt{method.label}  Set according method used.
\texttt{rq.method}  character, method used.
\texttt{rho, n}  numeric values extracted or computed from fit object.
\texttt{hjust, vjust}  Set to "inward" to override the default of the "text" geom.
\texttt{quantile}  Numeric value of the quantile used for the fit
\texttt{quantile.f}  Factor with a level for each quantile

If output.type is "numeric" the returned tibble contains columns in addition to a modified version of the original group:

\texttt{x.npcx}  x position
\texttt{y.npcy}  y position
\texttt{coef.ls}  list containing the "coefficients" matrix from the summary of the fit object
\texttt{rho, AIC, n}  numeric values extracted or computed from fit object
\texttt{rq.method}  character, method used.
\texttt{hjust, vjust}  Set to "inward" to override the default of the "text" geom.
\texttt{quantile}  Indicating the quantile used for the fit
\texttt{quantile.f}  Factor with a level for each quantile
\texttt{b_0.constant}  TRUE is polynomial is forced through the origin
\texttt{b_i}  One or columns with the coefficient estimates

To explore the computed values returned for a given input we suggest the use of \texttt{geom_debug} as shown in the example below.

\textbf{Note}

For backward compatibility a logical is accepted as argument for \texttt{eq.with.lhs}. If TRUE, the default is used, either "x" or "y", depending on the argument passed to \texttt{formula}. However, "x" or "y" can be substituted by providing a suitable replacement character string through \texttt{eq.x.rhs}. Parameter orientation is redundant as it only affects the default for \texttt{formula} but is included for consistency with \texttt{ggplot2::stat_smooth(\ldots)}.

R option \texttt{OutDec} is obeyed based on its value at the time the plot is rendered, i.e., displayed or printed. Set \texttt{options(OutDec = ",")} for languages like Spanish or French.

Support for the angle aesthetic is not automatic and requires that the user passes as argument suitable numeric values to override the defaults for label positions.

See Also

The quantile fit is done with function \texttt{rq}, please consult its documentation. This \texttt{stat_quant_eq} statistic can return ready formatted labels depending on the argument passed to \texttt{output.type}. This is possible because only polynomial models are supported. For other types of models, statistics \texttt{stat_fit_glance}, \texttt{stat_fit_tidy} and \texttt{stat_fit_glance} should be used instead and the code for construction of character strings from numeric values and their mapping to aesthetic label needs to be explicitly supplied in the call.

**stat_quant_line**

**Predicted line from quantile regression fit**

### Description

Predicted values are computed and, by default, plotted. Depending on the fit method, a confidence band can be computed and plotted. The confidence band can be interpreted similarly as that produced by `stat_smooth()` and `stat_poly_line()`.

### Usage

```r
stat_quant_line(
  mapping = NULL,
  data = NULL,
  geom = "smooth",
  position = "identity",
  ..., 
  quantiles = c(0.25, 0.5, 0.75),
  formula = NULL,
  se = length(quantiles) == 1L,
  fm.values = FALSE,
  n = 80,
  method = "rq",
  method.args = list(),
  n.min = 3L,
  level = 0.95,
  type = "direct",
  interval = "confidence",
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)
```

### Arguments

- **mapping**: The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
- **data**: A layer specific dataset, only needed if you want to override the plot defaults.
- **geom**: The geometric object to use display the data
- **position**: The position adjustment to use for overlapping points on this layer
- **...**: other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.
quantiles numeric vector Values in 0..1 indicating the quantiles.
formula a formula object. Using aesthetic names x and y instead of original variable names.
se logical Passed to quantreg::predict.rq().
fm.values logical Add n as a column to returned data? (‘FALSE’ by default.)
n Number of points at which to evaluate smoother.
method function or character If character, "rq", "rqss" or the name of a model fit function are accepted, possibly followed by the fit function’s method argument separated by a colon (e.g. "rq:br"). If a function different to rq(), it must accept arguments named formula, data, weights, tau and method and return a model fit object of class rq, rqss or rqss.
method.args named list with additional arguments passed to rq(), rqss() or to a function passed as argument to method.
n.min integer Minimum number of distinct values in the explanatory variable (on the rhs of formula) for fitting to the attempted.
level numeric in range [0..1] Passed to quantreg::predict.rq().
type character Passed to quantreg::predict.rq().
interval character Passed to quantreg::predict.rq().
na.rm a logical indicating whether NA values should be stripped before the computation proceeds.
orientation character Either "x" or "y" controlling the default for formula.
show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

stat_quant_line() behaves similarly to ggplot2::stat_smooth() and stat_poly_line() but supports fitting regressions for multiple quantiles in the same plot layer. This statistic interprets the argument passed to formula accepting y as well as x as explanatory variable, matching stat_quant_eq(). While stat_quant_eq() supports only method "rq", stat_quant_line() and stat_quant_band() support both "rq" and "rqss", In the case of "rqss" the model formula makes normally use of qss() to formulate the spline and its constraints.

geom_smooth, which is used by default, treats each axis differently and thus is dependent on orientation. If no argument is passed to formula, it defaults to y ~ x. Formulas with y as explanatory variable are treated as if x was the explanatory variable and orientation = "y".

Package 'ggpmisc' does not define a new geometry matching this statistic as it is enough for the statistic to return suitable x, y, ymin, ymax and group values.

The minimum number of observations with distinct values in the explanatory variable can be set through parameter n.min. The default n.min = 3L is the smallest usable value. However, model fits with very few observations are of little interest and using larger values of n.min than the default is wise.
There are multiple uses for double regression on x and y. For example, when two variables are subject to mutual constrains, it is useful to consider both of them as explanatory and interpret the relationship based on them. So, from version 0.4.1 'ggpmisc' makes it possible to easily implement the approach described by Cardoso (2019) under the name of "Double quantile regression".

**Value**

The value returned by the statistic is a data frame, that will have n rows of predicted values and and their confidence limits for each quantile, with each quantile in a group. The variables are x and y with y containing predicted values. In addition, quantile and quantile.f indicate the quantile used and and edited group preserves the original grouping adding a new "level" for each quantile. Is se = TRUE, a confidence band is computed and values for it returned in ymax and ymin.

The value returned by the statistic is a data frame, that will have n rows of predicted values and their confidence limits. Optionally it will also include additional values related to the model fit.

**Computed variables**

`stat_quant_line()` provides the following variables, some of which depend on the orientation:

- `y *or* x` predicted value
- `ymin *or* xmin` lower confidence interval around the mean
- `ymax *or* xmax` upper confidence interval around the mean

If `fm.values = TRUE` is passed then one column with the number of observations n used for each fit is also included, with the same value in each row within a group. This is wasteful and disabled by default, but provides a simple and robust approach to achieve effects like colouring or hiding of the model fit line based on the number of observations.

**Aesthetics**

`stat_quant_line` understands x and y, to be referenced in the formula and weight passed as argument to parameter weights. All three must be mapped to numeric variables. In addition, the aesthetics understood by the geom (“geom_smooth” is the default) are understood and grouping respected.

```

swap_xy

Swap x and y in a formula

Description

By default a formula of x on y is converted into a formula of y on x, while the reverse swap is done only if backward = TRUE.

Usage

swap_xy(f, backwards = FALSE)

Arguments

f
  formula An R model formula

backwards  logical
This function is meant to be used only as a helper within 'ggplot2' statistics. Normally together with geometries supporting orientation when we want to automate the change in orientation based on a user-supplied formula. Only x and y are changed, and in other respects the formula is rebuilt copying the environment from f.

A copy of f with x and y swapped by each other in the lhs and rhs.

Expand scale limits to make them symmetric around zero. Can be passed as argument to parameter limits of continuous scales from packages 'ggplot2' or 'scales'. Can be also used to obtain an enclosing symmetric range for numeric vectors.

symmetric_limits(x)

numeric The automatic limits when used as argument to a scale’s limits formal parameter. Otherwise a numeric vector, possibly a range, for which to compute a symmetric enclosing range.

A numeric vector of length two with the new limits, which are always such that the absolute value of upper and lower limits is the same.

symmetric_limits(c(-1, 1.8))
symmetric_limits(c(-10, 1.8))
symmetric_limits(-5:20)
Assemble label and map it

Description

Assemble model-fit-derived text or expressions and map them to the label aesthetic.

Usage

use_label(
  labels = c("eq", "p.value"),
  other.mapping = NULL,
  sep = "\", "\"
)

Arguments

labels character A vector with the name of the label components in the order they will be included in the combined label.
other.mapping An unevaluated expression constructed with function aes to be included in the returned value.
sep character A string used as separator when pasting the label components together.

Details

Statistics \texttt{stat\_poly\_eq}, \texttt{stat\_ma\_eq}, \texttt{stat\_quant\_eq} and \texttt{stat\_correlation} return multiple text strings to be used individually or assembled into longer character strings depending on the labels actually desired. Assembling and mapping them requires verbose R code and familiarity with R expression syntax. Function \texttt{use\_label()} automates these two tasks and accepts abbreviated familiar names for the parameters in addition to the name of the columns in the data object returned by the statistics. The default separator is that for expressions. The statistics return variables with names ending in \texttt{.label}. This ending can be omitted, as well as \texttt{.f.value.label}, \texttt{.t.value.label}, \texttt{.z.value.label}, \texttt{.S.value.label} and \texttt{.p.value.label}. \texttt{R2} can be used in place of \texttt{rr}. Furthermore, case is ignored.

Function \texttt{use\_label()} calls \texttt{aes()} to create a mapping for the label aesthetic, but it can in addition combine this mapping with other mappings created with \texttt{aes()}.

Value

A mapping to the label aesthetic and optionally additional mappings as an unevaluated R expression, built using function \texttt{aes}, ready to be passed as argument to the mapping parameter of the supported statistics.

Note

Function \texttt{use\_label()} can be only used to generate an argument passed to formal parameter mapping of the statistics \texttt{stat\_poly\_eq}, \texttt{stat\_ma\_eq}, \texttt{stat\_quant\_eq} and \texttt{stat\_correlation}.

# example with other available components
ggplot(data = my.data,
xy_outcomes2factor

Convert two numeric ternary outcomes into a factor

Description

Convert two numeric ternary outcomes into a factor

Usage

xy_outcomes2factor(x, y)

xy_thresholds2factor(x, y, x_threshold = 0, y_threshold = 0)
xy_outcomes2factor

Arguments

x, y
numeric vectors of -1, 0, and +1 values, indicating down regulation, uncertain response or up-regulation, or numeric vectors that can be converted into such values using a pair of thresholds.

x_threshold, y_threshold
numeric vector Ranges enclosing the values to be considered uncertain for each of the two vectors.

Details

This function converts the numerically encoded values into a factor with the four levels "xy", "x", "y" and "none". The factor created can be used for faceting or can be mapped to aesthetics.

Note

This is an utility function that only saves some typing. The same result can be achieved by a direct call to `factor`. This function aims at making it easier to draw quadrant plots with facets based on the combined outcomes.
