Package ‘groupdata2’

June 6, 2020

Title  Creating Groups from Data
Version  1.2.1
Description  Methods for dividing data into groups.
Create balanced partitions and cross-validation folds.
Perform time series windowing and general grouping and splitting of data.
Balance existing groups with up- and downsampling.
Depends  R (>= 3.5)

**all_groups_identical**

Test if two grouping factors contain the same groups.

**Description**

**Maturing**
Checks whether two grouping factors contain the same groups, looking only at the group members, allowing for different group names / identifiers.

**Usage**

all_groups_identical(x, y)

**Arguments**

x, y
Two grouping factors (vectors/factors with group identifiers) to compare.

**N.B.** Both are converted to character vectors.

**Details**

Both factors are sorted by x. A grouping factor is created with new groups starting at the values in y which differ from the previous row (i.e. `group()` with method = "l_starts" and n = "auto"). A similar grouping factor is created for x, to have group identifiers range from 1 to the number of groups. The two generated grouping factors are tested for equality.

**Value**

Whether all groups in x are the same in y, memberwise. (logical)

**Author(s)**

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>
Balance groups by up- and downsampling.

Description

Maturing

Uses up- and/or downsampling to fix the group sizes to the min, max, mean, or median group size or to a specific number of rows. Has a range of methods for balancing on ID level.

Usage

balance(
  data,
  size,
  cat_col,
  id_col = NULL,
  id_method = "n_ids",
  mark_new_rows = FALSE,
  new_rows_col_name = ".new_row"
)
Arguments

data

Size to fix group sizes to. Can be a specific number, given as a whole number, or one of the following strings: "min", "max", "mean", "median".

number: Fix each group to have the size of the specified number of row. Uses downsampling for groups with too many rows and upsampling for groups with too few rows.

min: Fix each group to have the size of smallest group in the dataset. Uses downsampling on all groups that have too many rows.

max: Fix each group to have the size of largest group in the dataset. Uses upsampling on all groups that have too few rows.

mean: Fix each group to have the mean group size in the dataset. The mean is rounded. Uses downsampling for groups with too many rows and upsampling for groups with too few rows.

median: Fix each group to have the median group size in the dataset. The median is rounded. Uses downsampling for groups with too many rows and upsampling for groups with too few rows.

cat_col

Name of categorical variable to balance by. (Character)

id_col

Name of factor with IDs. (Character)

IDs are considered entities, e.g. allowing us to add or remove all rows for an ID. How this is used is up to the id_method.

E.g. If we have measured a participant multiple times and want make sure that we keep all these measurements. Then we would either remove/add all measurements for the participant or leave in all measurements for the participant.

id_method

Method for balancing the IDs. (Character)

n_ids, n_rows_c, distributed, or nested.

n_ids (default): Balances on ID level only. It makes sure there are the same number of IDs for each category. This might lead to a different number of rows between categories.

n_rows_c: Attempts to level the number of rows per category, while only removing/adding entire IDs. This is done in 2 steps:

1. If a category needs to add all its rows one or more times, the data is repeated.

2. Iteratively, the ID with the number of rows closest to the lacking/excessive number of rows is added/removed. This happens until adding/removing the closest ID would lead to a size further from the target size than the current size. If multiple IDs are closest, one is randomly sampled.

distributed: Distributes the lacking/excess rows equally between the IDs. If the number to distribute can not be equally divided, some IDs will have 1 row more/less than the others.

nested: Calls balance() on each category with IDs as cat_col. I.e. if size is "min", IDs will have the size of the smallest ID in their category.

mark_new_rows

Add column with 1s for added rows, and 0s for original rows. (Logical)

new_rows_col_name

Name of column marking new rows. Defaults to ".new_row".
Details

**Without** `id_col`: Upsampling is done with replacement for added rows, while the original data remains intact. Downsampling is done without replacement, meaning that rows are not duplicated but only removed.

**With** `id_col`: See `id_method` description.

Value

Data frame with added and/or deleted rows. Ordered by `cat_col` and (potentially) `id_col`.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other sampling functions: `downsample()`, `upsample()`

Examples

```r
# Attach packages
library(groupdata2)

# Create data frame
df <- data.frame(
  "participant" = factor(c(1, 1, 2, 3, 3, 3, 3, 4, 4, 5, 5, 5, 5)),
  "diagnosis" = factor(c(0, 0, 1, 0, 0, 0, 0, 1, 1, 0, 0, 0, 0)),
  "trial" = c(1, 2, 1, 1, 2, 3, 4, 1, 2, 1, 2, 3, 4),
  "score" = sample(c(1:100), 13)
)

# Using balance() with specific number of rows
balance(df, 3, cat_col = "diagnosis")

# Using balance() with min
balance(df, "min", cat_col = "diagnosis")

# Using balance() with max
balance(df, "max", cat_col = "diagnosis")

# Using balance() with id_method "n_ids"
# With column specifying added rows
balance(df, "max",
  cat_col = "diagnosis",
  id_col = "participant",
  id_method = "n_ids",
  mark_new_rows = TRUE
)

# Using balance() with id_method "n_rows_c"
# With column specifying added rows
balance(df, "max",
  cat_col = "diagnosis",
  id_col = "participant",
  id_method = "n_rows_c",
  mark_new_rows = TRUE
)
```
differs_from_previous

Find values in a vector that differ from the previous value.

Description

Maturing
Finds values, or indices of values, that differ from the previous value by some threshold(s).
Operates with both a positive and a negative threshold. Depending on direction, it checks if the difference to the previous value is:

• greater than or equal to the positive threshold.
• less than or equal to the negative threshold.

Usage
differs_from_previous(
data,  
col = NULL,  
threshold = NULL,  
direction = "both",  
return_index = FALSE,  
include_first = FALSE,  
handle_na = "ignore",  
factor_conversion_warning = TRUE
)

Arguments
data
Data frame or Vector
N.B. If checking a factor, it is converted to a character vector. This means that factors can only be used when threshold is NULL. Conversion will generate a
warning, which can be turned off by setting `factor_conversion_warning` to `FALSE`.

**col**
Name of column to find values that differ in. Used when data is data frame. (Character)

**threshold**
Threshold to check difference to previous value to.
NULL, numeric scalar or numeric vector with length 2.
- **NULL**: Checks if the value is different from the previous value. Ignores direction.
  - N.B. Works for both numeric and character vectors.
- **Numeric scalar**: Positive number. Negative threshold is the negated number.
  - N.B. Only works for numeric vectors.
- **Numeric vector with length 2**: Given as `c(negative threshold, positive threshold)`. Negative threshold must be a negative number and positive threshold must be a positive number.
  - N.B. Only works for numeric vectors.

**direction**
both, positive or negative. (character)
- **both**: Checks whether the difference to the previous value is
  • greater than or equal to the positive threshold.
  • less than or equal to the negative threshold.
- **positive**: Checks whether the difference to the previous value is
  • greater than or equal to the positive threshold.
- **negative**: Checks whether the difference to the previous value is
  • less than or equal to the negative threshold.

**return_index**
Return indices of values that differ. (Logical)

**include_first**
Whether to include first element in vector in output. (Logical)

**handle_na**
How to handle `NA`s in the column.
  - "ignore": Removes the `NA`s before finding the differing values, ensuring that the first value after an `NA` will be correctly identified as new, if it differs from the value before the `NA`(s).
  - "as_element": Treats all `NA`s as the string "NA". This means, that `threshold` must be `NULL` when using this method.

**factor_conversion_warning**
Generate warning when converting factor to character. (Logical)

---

### Value
Vector with either differing values or indices of differing values.

### Author(s)
Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

### See Also
Other `l_starts` tools: `find_missing_starts()`, `find_starts()`, `group_factor()`, `group()`
Examples

```r
# Attach packages
library(groupdata2)

# Create a data frame
df <- data.frame(
  "a" = factor(c("a", "a", "b", "b", "c", "c")),
  "n" = c(1, 3, 6, 2, 2, 4)
)

# Get differing values in column 'a' with no threshold.
# This will simply check, if it is different to the previous value or not.
differs_from_previous(df, col = "a")

# Get indices of differing values in column 'a' with no threshold.
differs_from_previous(df, col = "a", return_index = TRUE)

# Get values, that are 2 or more greater than the previous value
differs_from_previous(df, col = "n", threshold = 2, direction = "positive")

# Get values, that are 4 or more less than the previous value
differs_from_previous(df, col = "n", threshold = 4, direction = "negative")

# Get values, that are either 2 or more greater than the previous value
# or 4 or more less than the previous value
differs_from_previous(df, col = "n", threshold = c(-4, 2), direction = "both")
```

downsample

**Downsampling of rows in a data frame.**

description

**Maturing**

Uses random downsampling to fix the group sizes to the smallest group in the data frame.

Wraps `balance()`.

Usage

```
downsample(data, cat_col, id_col = NULL, id_method = "n_ids")
```

Arguments

- `data` Data frame.
- `cat_col` Name of categorical variable to balance by. (Character)
- `id_col` Name of factor with IDs. (Character)

IDs are considered entities, e.g. allowing us to add or remove all rows for an ID. How this is used is up to the `id_method`.

E.g. If we have measured a participant multiple times and want make sure that we keep all these measurements. Then we would either remove/add all measurements for the participant or leave in all measurements for the participant.
id_method

Method for balancing the IDs. (Character)

n_ids, n_rows_c, distributed, or nested.

n_ids (default): Balances on ID level only. It makes sure there are the same number of IDs for each category. This might lead to a different number of rows between categories.

n_rows_c: Attempts to level the number of rows per category, while only removing/adding entire IDs. This is done in 2 steps:
1. If a category needs to add all its rows one or more times, the data is repeated.
2. Iteratively, the ID with the number of rows closest to the lacking/excessive number of rows is added/removed. This happens until adding/removing the closest ID would lead to a size further from the target size than the current size. If multiple IDs are closest, one is randomly sampled.

distributed: Distributes the lacking/excess rows equally between the IDs. If the number to distribute can not be equally divided, some IDs will have 1 row more/less than the others.

nested: Calls balance() on each category with IDs as cat_col. I.e. if size is "min", IDs will have the size of the smallest ID in their category.

Details

Without id_col: Downsampling is done without replacement, meaning that rows are not duplicated but only removed.

With id_col: See id_method description.

Value

Data frame with some rows removed. Ordered by cat_col and (potentially) id_col.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other sampling functions: balance(), upsample()

Examples

# Attach packages
library(groupdata2)

# Create data frame
df <- data.frame(
  "participant" = factor(c(1, 1, 2, 3, 3, 3, 3, 4, 4, 5, 5, 5, 5)),
  "diagnosis" = factor(c(0, 0, 1, 0, 0, 0, 0, 1, 1, 0, 0, 0, 0)),
  "trial" = c(1, 2, 1, 1, 2, 3, 4, 1, 2, 1, 2, 3, 4),
  "score" = sample(c(1:100), 13)
)

# Using downsample()
downsample(df, cat_col = "diagnosis")
find_missing_starts

Find start positions that cannot be found in data.

Description

Maturing

Tells you which values and (optionally) skip_to numbers that are recursively removed when using the l_starts method with remove_missing_starts set to TRUE.

Usage

find_missing_starts(data, n, starts_col = NULL, return_skip_numbers = TRUE)

Arguments

data Data frame or Vector
n List of starting positions. Skip values by c(value, skip_to_number) where skip_to_number is the nth appearance of the value in the vector.
See group_factor for explanations and examples of using the l_starts method.
starts_col Name of column with values to match when data is a data frame. Pass 'index' to use row names. (Character)
find_starts

return_skip_numbers

Return skip_to numbers along with values (Logical).

Value

List of start values and skip_to numbers or vector of the start values. Returns NULL if no values found.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other l_starts tools: differs_from_previous(), find_starts(), group_factor(), group()

Examples

# Attach packages
library(groupdata2)

# Create a data frame
df <- data.frame(
  "a" = c("a", "a", "b", "b", "c", "c"),
  stringsAsFactors = FALSE
)

# Create list of starts
starts <- c("a", "e", "b", "d", "c")

# Find missing starts with skip_to numbers
find_missing_starts(df, starts, starts_col = "a")

# Find missing starts without skip_to numbers
find_missing_starts(df, starts, 
  starts_col = "a", 
  return_skip_numbers = FALSE
)

find_starts

Find start positions of groups in data.

Description

Maturing

Finds values or indices of values that are not the same as the previous value.
E.g. to use with the l_starts method.
Wraps differs_from_previous().
Usage

```r
find_starts(
  data,
  col = NULL,
  return_index = FALSE,
  handle_na = "ignore",
  factor_conversion_warning = TRUE
)
```

Arguments

data: Data frame or Vector
N.B. If checking a factor, it is converted to a character vector. Conversion will generate a warning, which can be turned off by setting `factor_conversion_warning` to `FALSE`.
col: Name of column to find starts in. Used when data is data frame. (Character)
return_index: Return indices of starts. (Logical)
handle_na: How to handle NAs in the column.
  "ignore": Removes the NAs before finding the differing values, ensuring that the first value after an NA will be correctly identified as new, if it differs from the value before the NA(s).
  "as_element": Treats all NAs as the string "NA". This means, that `threshold` must be `NULL` when using this method.
  Numeric scalar: A numeric value to replace NAs with.
factor_conversion_warning: Generate warning when converting factor to character. (Logical)

Value

Vector with either start values or indices of start values.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other l_starts tools: `differs_from_previous()`, `find_missing_starts()`, `group_factor()`, `group()`

Examples

```r
# Attach packages
library(groupdata2)

# Create a data frame
df <- data.frame(
  "a" = c("a", "a", "b", "b", "c", "c"),
  stringsAsFactors = FALSE
)
```
fold

Create balanced folds for cross-validation.

Description

Stable
Divides data into groups by a range of methods. Balances a given categorical variable and/or numerical variable between folds and keeps (if possible) all data points with a shared ID (e.g. participant_id) in the same fold. Can create multiple unique fold columns for repeated cross-validation.

Usage

fold(
  data,
  k = 5,
  cat_col = NULL,
num_col = NULL,
id_col = NULL,
method = "n_dist",
id_aggregation_fn = sum,
extreme_pairing_levels = 1,
num_fold_cols = 1,
unique_fold_cols_only = TRUE,
max_iters = 5,
handle_existing_fold_cols = "keep_warn",
parallel = FALSE
)

Arguments

data  
Data frame.
k  
Dependent on method.
Number of folds (default), fold size, with more (see method).
Given as whole number or percentage (0 < n < 1).
cat_col  
Name of categorical variable to balance between folds.
E.g. when predicting a binary variable (a or b), we usually want both classes
represented in every fold.
N.B. If also passing an id_col, cat_col should be constant within each ID.
num_col  
Name of numerical variable to balance between folds.
N.B. When used with id_col, values for each ID are aggregated using id_aggregation_fn
before being balanced.
N.B. When passing num_col, the method parameter is ignored.
id_col  
Name of factor with IDs. This will be used to keep all rows that share an ID in
the same fold (if possible).
E.g. If we have measured a participant multiple times and want to see the effect
of time, we want to have all observations of this participant in the same fold.
method  
Method to choose from: n_dist, n_fill, n_last, n_rand, greedy, or staircase.
Notice: examples are sizes of the generated groups based on a vector with 57 elements.

n_dist (default):  
Divides the data into a specified number of groups and
distributes excess data points across groups (e.g. 11, 11, 12, 11, 12).
n is number of groups

n_fill:  
Divides the data into a specified number of groups and fills up groups
with excess data points from the beginning (e.g. 12, 11, 11, 11, 11).
n is number of groups

n_last:  
Divides the data into a specified number of groups. It finds the most
equal group sizes possible, using all data points. Only the last group is able to
differ in size (e.g. 11, 11, 11, 11, 13).
n is number of groups

n_rand:  
Divides the data into a specified number of groups. Excess data
points are placed randomly in groups (only 1 per group) (e.g. 12, 11, 11, 11, 12).
n is number of groups

greedy:  
Divides up the data greedily given a specified group size (e.g. 10, 10, 10, 10, 7).
n is group size
**fold**

**staircase:** Uses step size to divide up the data. Group size increases with 1 step for every group, until there is no more data (e.g. 5, 10, 15, 20, 7). 

n is step size

**id_aggregation_fn**

Function for aggregating values in num_col for each ID, before balancing num_col. N.B. Only used when num_col and id_col are both specified.

**extreme_pairing_levels**

How many levels of extreme pairing to do when balancing folds by a numerical column (i.e. num_col is specified).

**Extreme pairing:** Rows/pairs are ordered as smallest, largest, second smallest, second largest, etc. If extreme_pairing_levels > 1, this is done "recursively" on the extreme pairs. See "Details/num_col" for more.

N.B. Larger values work best with large datasets. If set too high, the result might not be stochastic. Always check if an increase actually makes the folds more balanced. See example.

**num_fold_cols**

Number of fold columns to create. Useful for repeated cross-validation. If num_fold_cols > 1, columns will be named "folds1", "folds2", etc. Otherwise simply "folds".

N.B. If unique_fold_cols_only is TRUE, we can end up with fewer columns than specified, see max_iters.

N.B. If data has existing fold columns, see handle_existing_fold_cols.

**unique_fold_cols_only**

Check if fold columns are identical and keep only unique columns. As the number of column comparisons can be time consuming, we can run this part in parallel. See parallel.

N.B. We can end up with fewer columns than specified in num_fold_cols, see max_iters.

N.B. Only used when num_fold_cols > 1 or data has existing fold columns.

**max_iters**

Maximum number of attempts at reaching num_fold_cols unique fold columns. When only keeping unique fold columns, we risk having fewer columns than expected. Hence, we repeatedly create the missing columns and remove those that are not unique. This is done until we have num_fold_cols unique fold columns or we have attempted max_iters times. In some cases, it is not possible to create num_fold_cols unique combinations of the dataset, e.g. when specifying cat_col, id_col and num_col. max_iters specifies when to stop trying. Note that we can end up with fewer columns than specified in num_fold_cols.

N.B. Only used num_fold_cols > 1.

**handle_existing_fold_cols**

How to handle existing fold columns. Either "keep.warn", "keep", or "remove". To add extra fold columns, use "keep" or "keep.warn". Note that existing fold columns might be renamed.

To replace the existing fold columns, use "remove".

**parallel**

Whether to parallelize the fold column comparisons, when unique_fold_cols_only is TRUE.

Requires a registered parallel backend. Like doParallel::registerDoParallel.

**Details**

**cat_col:**
1. Data is subset by `cat_col`.
2. Subsets are grouped and merged.

**id_col:**
1. Groups are created from unique IDs.

**num_col:**
1. Rows are shuffled.
   - \textbf{Note} that this will only affect rows with the same value in `num_col`.
   - Each pair get a group identifier.
   - If `extreme_pairing_levels > 1`: The group identifiers are reordered as smallest, largest, second smallest, second largest, etc., by the sum of `num_col` in the represented pairs. These pairs (of pairs) get a new set of group identifiers, and the process is repeated until there are `2^{extreme_pairing_levels-2}` rows. Note that the group identifiers at the last level will represent `2^{extreme_pairing_levels-2}` rows, why you should be careful when choosing that setting.
   - The final group identifiers are folded, and the fold identifiers are transferred to the rows.

N.B. When doing extreme pairing of an unequal number of rows, the row with the smallest value is placed in a group by itself, and the order is instead: smallest, second smallest, largest, third smallest, second largest, etc.

**cat_col AND id_col:**
1. Data is subset by `cat_col`.
2. Groups are created from unique IDs in each subset.
3. Subsets are merged.

**cat_col AND num_col:**
1. Data is subset by `cat_col`.
2. Subsets are grouped by `num_col`.
3. Subsets are merged such that the largest group (by sum of `num_col`) from the first category is merged with the smallest group from the second category, etc.

**num_col AND id_col:**
1. Values in `num_col` are aggregated for each ID, using `id_aggregation_fn`.
2. The IDs are grouped, using the aggregated values as "num_col".
3. The groups of the IDs are transferred to the rows.

**cat_col AND num_col AND id_col:**
1. Values in `num_col` are aggregated for each ID, using `id_aggregation_fn`.
2. IDs are subset by `cat_col`.
3. The IDs in each subset are grouped, by using the aggregated values as "num_col".
4. The subsets are merged such that the largest group (by sum of the aggregated values) from the first category is merged with the smallest group from the second category, etc.
5. The groups of the IDs are transferred to the rows.

**Value**
Data frame with grouping factor for subsetting in cross-validation.

Examples

# Attach packages
library(groupdata2)
library(dplyr)

# Create data frame
df <- data.frame(
  "participant" = factor(rep(c("1", "2", "3", "4", "5", "6"), 3)),
  "age" = rep(sample(c(1:100), 6), 3),
  "diagnosis" = factor(rep(c("a", "b", "a", "a", "b", "b"), 3)),
  "score" = sample(c(1:100), 3 * 6)
)
df <- df %>% arrange(participant)
df$session <- rep(c("1", "2", "3"), 6)

# Using fold()

## Without balancing
df_folded <- fold(df, 3, method = "n_dist")

## With cat_col
df_folded <- fold(df, 3, 
  cat_col = "diagnosis", 
  method = "n_dist"
)

## With id_col
df_folded <- fold(df, 3, 
  id_col = "participant", 
  method = "n_dist"
)

## With num_col
# Note: 'method' would not be used in this case
df_folded <- fold(df, 3, num_col = "score")

# With cat_col and id_col
df_folded <- fold(df, 3, 
  cat_col = "diagnosis", 
  id_col = "participant", method = "n_dist"
)

## With cat_col, id_col and num_col
df_folded <- fold(df, 3, 
  cat_col = "diagnosis", 
  id_col = "participant", num_col = "score"
Create groups from your data.

**Description**

**Stable**

Divides data into groups by a range of methods. Creates a grouping factor with 1s for group 1, 2s for group 2, etc. Returns a data frame grouped by the grouping factor for easy use in `%>%` pipelines.

**Usage**

```r
group(data,
```
Arguments

data  Data frame or vector.
n  Number of groups (default), group size, list of group sizes, list of group starts, step size or prime number to start at. See method. Passed as whole number(s) and/or percentage(s) ($0 < n < 1$) and/or character. Method l_starts allows 'auto'.

method  greedy, n_dist, n_fill, n_last, n_rand, l_sizes, l_starts, staircase, or primes.

Notice: examples are sizes of the generated groups based on a vector with 57 elements.

greedy: Divides up the data greedily given a specified group size (e.g. 10, 10, 10, 10, 10, 7). n is group size

n_dist (default): Divides the data into a specified number of groups and distributes excess data points across groups (e.g. 11, 11, 12, 11, 12). n is number of groups

n_fill: Divides the data into a specified number of groups and fills up groups with excess data points from the beginning (e.g. 12, 12, 11, 11, 11). n is number of groups

n_last: Divides the data into a specified number of groups. It finds the most equal group sizes possible, using all data points. Only the last group is able to differ in size (e.g. 11, 11, 11, 11, 13). n is number of groups

n_rand: Divides the data into a specified number of groups. Excess data points are placed randomly in groups (only 1 per group) (e.g. 12, 11, 11, 11, 12). n is number of groups

l_sizes: Divides up the data by a list of group sizes. Excess data points are placed in an extra group at the end. (e.g. $n = list(0.2, 0.3) + outputsgroupswithsizes(11, 17, 29)$). n is a list of group sizes

l_starts: Starts new groups at specified values of vector. n is a list of starting positions. Skip values by c(value, skip_to_number) where skip_to_number is the nth appearance of the value in the vector. Groups automatically start from first data point. E.g. $n = c(1, 3, 7, 25, 50) + outputsgroupswithsizes(2, 4, 18, 25, 8)$. To skip: givenvector("a", "e", "o", "a", "e", "o"). $n = list("a", "e", c("o", 2)) + outputsgroupswithsizes(2, 4, 18, 25, 8)$.

*group*

n,
method = "n_dist",
starts_col = NULL,
force_equal = FALSE,
allow_zero = FALSE,
return_factor = FALSE,
descending = FALSE,
randomize = FALSE,
col_name = ".groups",
remove_missing_starts = FALSE
)
If passing \( n = 'auto' \) the starting positions are automatically found with `find_starts()`. Note that all \( \text{NAs} \) are first replaced by a single unique value, meaning that they will also cause group starts.

- **staircase**: Uses step size to divide up the data. Group size increases with 1 step for every group, until there is no more data (\( e.g. 5, 10, 15, 20, 7 \)).
  - \( n \) is step size

- **primes**: Uses prime numbers as group sizes. Group size increases to the next prime number until there is no more data. (\( e.g. 5, 7, 11, 13, 17, 4 \)).
  - \( n \) is the prime number to start at

- **starts_col**: Name of column with values to match in method `1_starts` when data is a data frame. Pass `index` to use row names. (Character)
- **force_equal**: Create equal groups by discarding excess data points. Implementation varies between methods. (Logical)
- **allow_zero**: Whether \( n \) can be passed as 0. (Logical)
- **return_factor**: Return only grouping factor. (Logical)
- **descending**: Change direction of method. (Not fully implemented) (Logical)
- **randomize**: Randomize the grouping factor (Logical)
- **col_name**: Name of added grouping factor
- **remove_missing_starts**: Recursively remove elements from the list of starts that are not found. For method `1_starts` only. (Logical)

**Value**
Data frame grouped by new grouping factor

**Author(s)**
Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

**See Also**
Other grouping functions: `all_groups_identical()`, `fold()`, `group_factor()`, `partition()`, `splt()`

Other staircase tools: `%primes%()`, `%staircase%()`, `group_factor()`

Other `l_starts` tools: `differs_from_previous()`, `find_missing_starts()`, `find_starts()`, `group_factor()`

**Examples**
```
# Attach packages
library(groupdata2)
library(dplyr)

# Create data frame
df <- data.frame(
  "x" = c(1:12),
  "species" = factor(rep(c("cat", "pig", "human"), 4)),
  "age" = sample(c(1:100), 12)
)
```
# Using `group()`

```r
df_grouped <- group(df, 5, method = "n_dist")
```

# Using `group()` with dplyr pipeline to get mean age

```r
df_means <- df %>%
  group(5, method = "n_dist") %>%
dplyr::summarise(mean_age = mean(age))
```

# Using `group_factor()` with l_starts
  # "c('pig',2)" skips to the second appearance of
  # "pig" after the first appearance of "cat"

```r
df_grouped <- group(df,
  list("cat", c("pig", 2), "human"),
  method = "l_starts",
  starts_col = "species"
)
```

---

**groupdata2**

A package for creating groups from data

---

**Description**

Methods for dividing data into groups. Create balanced partitions and cross-validation folds. Perform time series windowing and general grouping and splitting of data. Balance existing groups with up- and downsampling.

**Details**

The `groupdata2` package provides six main functions: `group`, `group_factor`, `splt`, `partition`, `fold`, and `balance`.

**group**

Create groups from your data.

Divides data into groups by a range of methods. Creates a grouping factor with 1s for group 1, 2s for group 2, etc. Returns a data frame grouped by the grouping factor for easy use in dplyr pipelines.

Go to `group`

**group_factor**

Create grouping factor for subsetting your data.

Divides data into groups by a range of methods. Creates and returns a grouping factor with 1s for group 1, 2s for group 2, etc.

Go to `group_factor`

**splt**

Split data by a range of methods.

Divides data into groups by a range of methods. Splits data by these groups.

Go to `splt`
**partition**

Create balanced partitions (e.g. training/test sets).

Splits data into partitions. Balances a given categorical variable between partitions and keeps (if possible) all data points with a shared ID (e.g. participant_id) in the same partition.

Go to **partition**

**fold**

Create balanced folds for cross-validation.

Divides data into groups (folds) by a range of methods. Balances a given categorical variable between folds and keeps (if possible) all data points with the same ID (e.g. participant_id) in the same fold.

Go to **fold**

**balance**

Balance the sizes of your groups with up- and downsampling.

Uses up- and/or downsampling to fix the group sizes to the min, max, mean, or median group size or to a specific number of rows. Has a range of methods for balancing on ID level.

Go to **balance**

**Author(s)**

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

---

**group_factor**

Create grouping factor for subsetting your data.

**Description**

**Stable**

Divides data into groups by a range of methods. Creates and returns a grouping factor with 1s for group 1, 2s for group 2, etc.

**Usage**

```r
group_factor(
  data,
  n,
  method = "n_dist",
  starts_col = NULL,
  force_equal = FALSE,
  allow_zero = FALSE,
  descending = FALSE,
  randomize = FALSE,
  remove_missing_starts = FALSE
)
```
### Arguments

<table>
<thead>
<tr>
<th>data</th>
<th>Data frame or vector.</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td><em>Dependent on method.</em> Number of groups (default), group size, list of group sizes, list of group starts, step size or prime number to start at. See method. Passed as whole number(s) and/or percentage(s) ((0 &lt; n &lt; 1)) and/or character. Method <code>l_starts</code> allows <code>'auto'</code>.</td>
</tr>
<tr>
<td>method</td>
<td><code>greedy</code>, <code>n_dist</code>, <code>n_fill</code>, <code>n_last</code>, <code>n_rand</code>, <code>l_sizes</code>, <code>l_starts</code>, <code>staircase</code>, or <code>primes</code>.</td>
</tr>
</tbody>
</table>

**Notice:** examples are sizes of the generated groups based on a vector with 57 elements.

- **greedy:** Divides up the data greedily given a specified group size *(e.g. 10, 10, 10, 10, 7)*. *n* is group size
- **n_dist (default):** Divides the data into a specified number of groups and distributes excess data points across groups *(e.g. 11, 11, 12, 12, 12)*. *n* is number of groups
- **n_fill:** Divides the data into a specified number of groups and fills up groups with excess data points from the beginning *(e.g. 12, 12, 11, 11, 11)*. *n* is number of groups
- **n_last:** Divides the data into a specified number of groups. It finds the most equal group sizes possible, using all data points. Only the last group is able to differ in size *(e.g. 11, 11, 11, 11, 13)*. *n* is number of groups
- **n_rand:** Divides the data into a specified number of groups. Excess data points are placed randomly in groups (only 1 per group) *(e.g. 12, 11, 11, 11, 12)*. *n* is number of groups
- **l_sizes:** Divides up the data by a list of group sizes. Excess data points are placed in an extra group at the end. *(e.g. \(n = \text{list}(0.2, 0.3)\) outputsgroupswithsizes(11, 17, 29)). *n* is a list of group sizes
- **l_starts:** Starts new groups at specified values of vector. *n* is a list of starting positions. Skip values by *c(value, skip_to_number)* where *skip_to_number* is the nth appearance of the value in the vector. Groups automatically start from first data point. *(e.g. \(n = \text{c}(1, 3, 7, 25, 50)\) outputsgroupswithsizes(2, 4, 18, 25, 8)). To skip: *givenvector(c("a","e","o","a","e","o"),n = list("a","e",c("o",2))) outputsgroupswithsizes(2,4,18,25,8)*. If passing \(n = 'auto'\) the starting positions are automatically found with `find_starts()`. Note that all \(\text{NAs}\) are first replaced by a single unique value, meaning that they will also cause group starts.
- **staircase:** Uses step size to divide up the data. Group size increases with 1 step for every group, until there is no more data *(e.g. 5, 10, 15, 20, 7)*. *n* is step size
- **primes:** Uses prime numbers as group sizes. Group size increases to the next prime number until there is no more data. *(e.g. 5, 7, 11, 13, 17, 4)*. *n* is the prime number to start at

| starts_col         | Name of column with values to match in method `l_starts` when data is a data frame. Pass 'index' to use row names. (Character) |

groups <- group_factor(df, list(0.2, 0.3), method = "l_sizes")
df$groups <- groups

# Using group_factor() with l_starts
groups <- group_factor(df, list("cat", c("pig", 2), "human"),
    method = "l_starts", starts_col = "species"
)
df$groups <- groups
Create balanced partitions.

Description

Stable
Splits data into partitions. Balances a given categorical variable and/or numerical variable between partitions and keeps (if possible) all data points with a shared ID (e.g. participant_id) in the same partition.

Usage

partition(
  data,
  p = 0.2,
  cat_col = NULL,
  num_col = NULL,
  id_col = NULL,
  id_aggregation_fn = sum,
  extreme_pairing_levels = 1,
  force_equal = FALSE,
  list_out = TRUE
)

Arguments

data  Data frame.
p  List or vector of partition sizes. Given as whole number(s) and/or percentage(s) (0 < n < 1). E.g. c(0.2, 3, 0.1).
cat_col  Name of categorical variable to balance between partitions.
N.B. When used with id_col, values in num_col for each ID are aggregated using id_aggregation_fn before being balanced.
num_col  Name of numerical variable to balance between partitions.
N.B. If also passing an id_col, cat_col should be constant within each ID.
id_col  Name of factor with IDs. Used to keep all rows that share an ID in the same partition (if possible).
E.g. If we have measured a participant multiple times and want to see the effect of time, we want to have all observations of this participant in the same partition.
id_aggregation_fn  Function for aggregating values in num_col for each ID, before balancing num_col.
N.B. Only used when num_col and id_col are both specified.
extreme_pairing_levels  How many levels of extreme pairing to do when balancing partitions by a numerical column (i.e. num_col is specified).
  Extreme pairing: Rows/pairs are ordered as smallest, largest, second smallest, second largest, etc. If extreme_pairing_levels > 1, this is done "recursively" on the extreme pairs. See "Details/num_col" for more.
N.B. Larger values work best with large datasets. If set too high, the result might not be stochastic. Always check if an increase actually makes the partitions more balanced. See example.

force_equal  Discard excess data. (Logical)
list_out     Return partitions in a list. (Logical)

Details

cat_col:
1. Data is subset by cat_col.
2. Subsets are partitioned and merged.

id_col:
1. Partitions are created from unique IDs.

num_col:
1. Rows are shuffled.
   \strong{Note} that this will only affect rows with the same value in code{num_col}.
   \item Extreme pairing 1: Rows are ordered as smallest, largest, second smallest, second largest, etc.
   Each pair get a group identifier.
   \item If code{extreme_pairing_levels} > 1: The group identifiers are reordered as smallest, largest, second smallest, second largest, etc., by the sum of code{num_col} in the represented rows.
   These pairs (of pairs) get a new set of group identifiers, and the process is repeated code{extreme_pairing_levels-2} times. Note that the group identifiers at the last level will represent code{2^extreme_pairing_levels} rows, why you should be careful when choosing that setting.
   \item The final group identifiers are shuffled, and their order is applied to the full dataset.
N.B. When doing extreme pairing of an unequal number of rows, the row with the largest value is placed in a group by itself, and the order is instead: smallest, second largest, second smallest, third largest, ... , largest.

cat_col AND id_col:
1. Data is subset by cat_col.
2. Partitions are created from unique IDs in each subset.
3. Subsets are merged.

cat_col AND num_col:
1. Data is subset by cat_col.
2. Subsets are partitioned by num_col.
3. Subsets are merged.

num_col AND id_col:
1. Values in num_col are aggregated for each ID, using id_aggregation_fn.
2. The IDs are partitioned, using the aggregated values as "num_col".
3. The partition identifiers are transferred to the rows of the IDs.

cat_col AND num_col AND id_col:
1. Values in num_col are aggregated for each ID, using id_aggregation_fn.
2. IDs are subset by cat_col.
3. The IDs for each subset are partitioned, by using the aggregated values as "num_col".
4. The partition identifiers are transferred to the rows of the IDs.
Value

If `list_out` is `TRUE`:

A list of partitions where partitions are data frames.

If `list_out` is `FALSE`:

A data frame with grouping factor for subsetting.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

Examples

```r
# Attach packages
library(groupdata2)
library(dplyr)

# Create data frame
df <- data.frame(
  "participant" = factor(rep(c("1", "2", "3", "4", "5", "6"), 3)),
  "age" = rep(sample(c(1:100), 6), 3),
  "diagnosis" = factor(rep(c("a", "b", "a", "a", "b", "b"), 3)),
  "score" = sample(c(1:100), 3 * 6)
)
df <- df %>% arrange(participant)
df$session <- rep(c("1", "2", "3"), 6)

# Using partition()

# Without balancing
partitions <- partition(data = df, p = c(0.2, 0.3))

# With cat_col
partitions <- partition(data = df, p = 0.5, cat_col = "diagnosis")

# With id_col
partitions <- partition(data = df, p = 0.5, id_col = "participant")

# With num_col
partitions <- partition(data = df, p = 0.5, num_col = "score")

# With cat_col and id_col
partitions <- partition(data = df, p = 0.5, cat_col = "diagnosis", id_col = "participant")

# With cat_col, num_col and id_col
partitions <- partition(data = df, p = 0.5, cat_col = "diagnosis", id_col = "participant")
```
p = 0.5, 
cat_col = "diagnosis", 
num_col = "score", 
id_col = "participant"
)

# Return data frame with grouping factor 
# with list_out = FALSE
partitions <- partition(df, c(0.5), list_out = FALSE)

# Check if additional extreme_pairing_levels 
# improve the numerical balance
set.seed(2) # try with seed 1 as well
partitions_1 <- partition(
  data = df, 
p = 0.5, 
num_col = "score",

)
partitions_2 %>%
dplyr::group_by(.partitions) %>%
dplyr::summarise(
  sum_score = sum(score),
  mean_score = mean(score)
)

---

**split**  
_Split data by a range of methods._

**Description**

**Stable**

Divides data into groups by a range of methods. Splits data by these groups.

**Usage**

```r
split(
  data, 
  n,
```
method = "n_dist",
starts_col = NULL,
force_equal = FALSE,
allow_zero = FALSE,
descending = FALSE,
randomize = FALSE,
remove_missing_starts = FALSE
)

Arguments

data
Data frame or vector.

n
Dependent on method.
Number of groups (default), group size, list of group sizes, list of group starts,
step size or prime number to start at. See method.
Passed as whole number(s) and/or percentage(s) \((0 < n < 1)\) and/or character.
Method \(l\_starts\) allows 'auto'.

method
greedy, n_dist, n_fill, n_last, n_rand, l_sizes, l_starts, staircase, or primes.

Notice: examples are sizes of the generated groups based on a vector with 57 elements.

\textbf{greedy:} Divides up the data greedily given a specified group size (e.g. 10, 10, 10, 10, 10, 7).
\(n\) is group size

\textbf{n_dist (default):} Divides the data into a specified number of groups and
distributes excess data points across groups (e.g. 11, 11, 12, 12, 11, 12).
\(n\) is number of groups

\textbf{n_fill:} Divides the data into a specified number of groups and fills up groups
with excess data points from the beginning (e.g. 12, 12, 11, 11, 11, 11).
\(n\) is number of groups

\textbf{n_last:} Divides the data into a specified number of groups. It finds the most
equal group sizes possible, using all data points. Only the last group is able to
differ in size (e.g. 11, 11, 11, 11, 13).
\(n\) is number of groups

\textbf{n_rand:} Divides the data into a specified number of groups. Excess data
points are placed randomly in groups (only 1 per group) (e.g. 12, 11, 11, 11, 12).
\(n\) is number of groups

\textbf{l_sizes:} Divides up the data by a list of group sizes. Excess data points are
placed in an extra group at the end. (e.g. \(n = list(0.2, 0.3)\) \(outputs\) \(group\) \(s\) \(with\) \(sizes\) (11, 17, 29)).
\(n\) is a list of group sizes

\textbf{l_starts:} Starts new groups at specified values of vector.
\(n\) is a list of starting positions. Skip values by \(c(\text{value}, \text{skip\_to\_number})\) where
\(\text{skip\_to\_number}\) is the \(n\)th appearance of the value in the vector. Groups auto-
matically start from first data point.
\(E.g.\ n = c(1, 3, 7, 25, 50)\) \(outputs\) \(groups\) \(with\) \(sizes\) (2, 4, 18, 25, 8).
To skip: \texttt{givenvector\("a", "e", "o", "a", "e", "o")}, \(n = list("a", "e", c("o", 2))\) \(outputs\) groups
If passing \(n = \text{'auto'}\) the starting positions are automatically found with \texttt{find\_starts()}. Note that all NAs are first replaced by a single unique value, meaning that they
will also cause group starts.
splt

staircase: Uses step size to divide up the data. Group size increases with 1 step for every group, until there is no more data (e.g. 5, 10, 15, 20, 7). 
n is step size

primes: Uses prime numbers as group sizes. Group size increases to the next prime number until there is no more data. (e.g. 5, 7, 11, 13, 17, 4). 
n is the prime number to start at

starts_col Name of column with values to match in method l_starts when data is a data frame. Pass 'index' to use row names. (Character)

force_equal Create equal groups by discarding excess data points. Implementation varies between methods. (Logical)

allow_zero Whether n can be passed as 0. (Logical)

descending Change direction of method. (Not fully implemented) (Logical)

randomize Randomize the grouping factor (Logical)

remove_missing_starts Recursively remove elements from the list of starts that are not found. For method l_starts only. (Logical)

Value

List of the split data

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

Other grouping functions: all_groups_identical(), fold(), group_factor(), group(), partition()

Examples

# Attach packages
library(groupdata2)
library(dplyr)

# Create data frame
df <- data.frame(
  "x" = c(1:12),
  "species" = factor(rep(c("cat", "pig", "human"), 4)),
  "age" = sample(c(1:100), 12)
)

# Using splt()
df_list <- splt(df, 5, method = "n_dist")
Description

Maturing
Uses random upsampling to fix the group sizes to the largest group in the data frame.
Wraps `balance()`.

Usage

```r
upsample(
  data,  # Data frame.
  cat_col,  # Name of categorical variable to balance by. (Character)
  id_col = NULL,  # Name of factor with IDs. (Character)
  id_method = "n_ids",  # IDs are considered entities, e.g. allowing us to add or remove all rows for an ID. How this is used is up to the id_method.
  mark_new_rows = FALSE,  # E.g. If we have measured a participant multiple times and want make sure that we keep all these measurements. Then we would either remove/add all measurements for the participant or leave in all measurements for the participant.
  new_rows_col_name = "new_row"
)
```

Arguments

- `data` Data frame.
- `cat_col` Name of categorical variable to balance by. (Character)
- `id_col` Name of factor with IDs. (Character)
- `id_method` Method for balancing the IDs. (Character)
  - `n_ids` (default): Balances on ID level only. It makes sure there are the same number of IDs for each category. This might lead to a different number of rows between categories.
  - `n_rows_c`: Attempts to level the number of rows per category, while only removing/adding entire IDs. This is done in 2 steps:
    1. If a category needs to add all its rows one or more times, the data is repeated.
    2. Iteratively, the ID with the number of rows closest to the lacking/excessive number of rows is added/removed. This happens until adding/removing the closest ID would lead to a size further from the target size than the current size. If multiple IDs are closest, one is randomly sampled.
  - `distributed`: Distributes the lacking/excess rows equally between the IDs. If the number to distribute can not be equally divided, some IDs will have 1 row more/less than the others.
  - `nested`: Calls `balance()` on each category with IDs as `cat_col`. I.e. if size is "min", IDs will have the size of the smallest ID in their category.
mark_new_rows Add column with 1s for added rows, and 0s for original rows. (Logical)
new_rows_col_name Name of column marking new rows. Defaults to ".new_row".

Details

Without id_col: Upsampling is done with replacement for added rows, while the original data remains intact.

With id_col: See id_method description.

Value

Data frame with added rows. Ordered by cat_col and (potentially) id_col.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>

See Also

)

---

%primes%

Find remainder from 'primes' method.

Description

Stable

When using the primes method, the last group might not have the size of the associated prime number if there are not enough elements left. Use %primes% to find this remainder.

Usage

size %primes% start_at

Arguments %primes%

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>Size to group (Integer)</td>
</tr>
<tr>
<td>start_at</td>
<td>Prime to start at (Integer)</td>
</tr>
</tbody>
</table>

Value

Remainder (Integer). Returns 0 if the last group has the size of the associated prime number.

Author(s)

Other remainder tools: %staircase%()
Examples

```r
# Attach packages
library(groupdata2)

100 %primes% 2
```

%staircase%  Find remainder from 'staircase' method.

Description

**Stable**
When using the staircase method, the last group might not have the size of the second last group + step size. Use %staircase% to find this remainder.

Usage

```r
size %staircase% step_size
```

Arguments

- `size` Size to staircase (Integer)
- `step_size` Step size (Integer)

Value

Remainder (Integer). Returns 0 if the last group has the size of the second last group + step size.

Author(s)

Ludvig Renbo Olsen, <r-pkgs@ludvigolsen.dk>
