Package ‘htmlTable’

October 12, 2021

Version  2.3.0

Title  Advanced Tables for Markdown/HTML

Maintainer  Max Gordon <max@gforge.se>

Description  Tables with state-of-the-art layout elements such as row spanners, column spanners, table spanners, zebra striping, and more. While allowing advanced layout, the underlying css-structure is simple in order to maximize compatibility with word processors such as 'MS Word' or 'LibreOffice'. The package also contains a few text formatting functions that help outputting text compatible with HTML/LaTeX.

License  GPL (>= 3)

URL  https://gforge.se/packages/

BugReports  https://github.com/gforge/htmlTable/issues

Biarch  yes

Imports  stringr, knitr (>= 1.6), magrittr (>= 1.5), methods, checkmate, htmlwidgets, htmltools, rstudioapi (>= 0.6)

Suggests  testthat, XML, xml2, Hmisc, reshape, rmarkdown, chron, lubridate, tibble, purrr, tidyselect, glue, rlang, tidyr (>= 0.7.2), dplyr (>= 0.7.4)

Encoding  UTF-8

NeedsCompilation  no

VignetteBuilder  knitr

RoxygenNote  7.1.2

**addHtmlTableStyle**

Add/set css and other style options

**Description**

This function is a preprocessing step before applying the `htmlTable()` function. You use this to style your tables with HTML cascading style sheet features.

**Usage**

```r
addHtmlTableStyle(
  x,
  align = NULL,
  align.header = NULL,
  align.cgroup = NULL,
  css.rgroup = NULL,
  css.rgroup.sep = NULL,
  css.tspanner = NULL,
```
addHtmlTableStyle

css.tspanner.sep = NULL,
css.total = NULL,
css.cell = NULL,
css.cgroup = NULL,
css.header = NULL,
css.header.border_bottom = NULL,
css.class = NULL,
css.table = NULL,
pos.rowlabel = NULL,
pos.caption = NULL,
col.rgroup = NULL,
col.columns = NULL,
padding.rgroup = NULL,
padding.tspanner = NULL,
spacer.celltype = NULL,
spacer.css.cgroup.bottom.border = NULL,
spacer.css = NULL,
spacer.content = NULL
)

appendHtmlTableStyle(
  x,
  align = NULL,
  align.header = NULL,
  align.cgroup = NULL,
  css.rgroup = NULL,
css.rgroup.sep = NULL,
css.tspanner = NULL,
css.tspanner.sep = NULL,
css.total = NULL,
css.cell = NULL,
css.cgroup = NULL,
css.header = NULL,
css.header.border_bottom = NULL,
css.class = NULL,
css.table = NULL,
pos.rowlabel = NULL,
pos.caption = NULL,
col.rgroup = NULL,
col.columns = NULL,
padding.rgroup = NULL,
padding.tspanner = NULL,
spacer.celltype = NULL,
spacer.css.cgroup.bottom.border = NULL,
spacer.css = NULL,
spacer.content = NULL
)
**Arguments**

- **x**: The object that you later want to pass into `htmlTable()`.

- **align**: A character strings specifying column alignments, defaulting to 'c' to center. Valid chars for alignments are l = left, c = center and r = right. You can also specify `align='c|c'` and other LaTeX tabular formatting. If you want to set the alignment of the rownames this string needst to be `ncol(x) + 1`, otherwise it automatically pads the string with a left alignment for the rownames.

- **align.header**: A character strings specifying alignment for column header, defaulting to centered, i.e. `[paste][base::paste](rep('c',ncol(x)),collapse='')`.

- **align.cgroup**: The justification of the cgroups

- **css.rgroup**: CSS style for the rgroup, if different styles are wanted for each of the rgroups you can just specify a vector with the number of elements.

- **css.rgroup.sep**: The line between different rgroups. The line is set to the TR element of the lower rgroup, i.e. you have to set the border-top/padding-top etc to a line with the expected function. This is only used for rgroups that are printed. You can specify different separators if you give a vector of `rgroup - 1` length (this is since the first rgroup doesn’t have a separator).

- **css.tspanner**: The CSS style for the table spanner.

- **css.tspanner.sep**: The line between different spanners.

- **css.total**: The css of the total row if such is activated.

- **css.cell**: The css.cell element allows you to add any possible CSS style to your table cells. See section below for details.

- **css.cgroup**: The same as `css.class` but for cgroup formatting.

- **css.header**: The header style, not including the cgroup style

- **css.header.border_bottom**: The header bottom-border style, e.g. `border-bottom: 1px solid grey`

- **css.class**: The html CSS class for the table. This allows directing html formatting through CSS directly at all instances of that class. **Note**: unfortunately the CSS is frequently ignored by word processors. This option is mostly inteded for web-presentations.

- **css.table**: You can specify the the style of the table-element using this parameter

- **pos.rowlabel**: Where the rowlabel should be positioned. This value can be "top", "bottom", "header", or a integer between 1 and `nrow(cgroup) + 1`. The options "bottom" and "header" are the same, where the row label is presented at the same level as the header.

- **pos.caption**: Set to "bottom" to position a caption below the table instead of the default of "top".

- **col.rgroup**: Alternating colors (zebra striping/banded rows) for each `rgroup`; one or two colors is recommended and will be recycled.

- **col.columns**: Alternating colors for each column.

- **padding.rgroup**: Generally two non-breakings spaces, i.e. `&nbsp;`, but some journals only have a bold face for the rgroup and leaves the subelements unindented.
**addHtmlTableStyle**

**padding.tspanner**

The table spanner is usually without padding but you may specify padding similar to padding.rgroup and it will be added to all elements, including the rgroup elements. This allows for a 3-level hierarchy if needed.

**spacer.celltype**

When using cgroup the table headers are separated through an empty HTML cell that is by default filled with &nbsp; (no-breaking-space) that prevents the cell from collapsing. The purpose of this is to prevent the headers underline to bleed into one as the underline is for the entire cell. You can alter this behavior by changing this option, valid options are single_empty, skip, double_cell. The single_empty is the default, the skip lets the header bleed into one and skips entirely, double_cell is for having two cells so that a vertical border ends up centered (specified using the align option). The arguments are matched internally using base::match.arg so you can specify only a part of the name, e.g. "sk" will match "skip".

**spacer.css.cgroup.bottom.border**

Defaults to none and used for separating cgroup headers. Due to a browser bug this is sometimes ignored and you may therefore need to set this to 1px solid white to enforce a white border.

**spacer.css**

If you want the spacer cells to share settings you can set it here

**spacer.content**

Defaults to &nbsp; as this guarantees that the cell is not collapsed and is highly compatible when copy-pasting to word processors.

**Details**

The function stores the current theme (see setHtmlTableTheme()) + custom styles to the provided object as an base::attributes(). It is stored under the element htmlTable.style in the form of a list object.

**Value**

x with the style added as an attribute that the htmlTable then can use for formatting.

**The css.cell argument**

The css.cell parameter allows you to add any possible CSS style to your table cells. css.cell can be either a vector or a matrix.

If css.cell is a vector, it's assumed that the styles should be repeated throughout the rows (that is, each element in css.cell specifies the style for a whole column of 'x').

In the case of css.cell being a matrix of the same size of the x argument, each element of x gets the style from the corresponding element in css.cell. Additionally, the number of rows of css.cell can be nrow(x) + 1 so the first row of of css.cell specifies the style for the header of x; also the number of columns of css.cell can be ncol(x) + 1 to include the specification of style for row names of x.

Note that the text-align CSS field in the css.cell argument will be overridden by the align argument.
Excel has a specific css-style, mso-number-format that can be used for improving the copy-paste functionality. E.g. the style could be written as: css_matrix <- matrix( data = "mso-number-format:\"\@\"", nrow = nrow(df), ncol = ncol(df))

See Also
Other htmlTableStyle: hasHtmlTableStyle()

Examples
library(magrittr)

  matrix(1:4, ncol = 2) %>%
  addHtmlTableStyle(align = "c", css.cell = "background-color: orange;") %>%
  htmlTable(caption = "A simple style example")

concatHtmlTables

Function for concatenating htmlTable()s

Description
Function for concatenating htmlTable()s

Usage
concatHtmlTables(tables, headers = NULL)

Arguments
tables  A list of htmlTable()s to be concatenated
headers Either a string or a vector of strings that function as a header for each table. If none is provided it will use the names of the table list or a numeric number.

Value
htmlTable() class object

Examples
library(magrittr)

  # Basic example
  output <- matrix(1:4, 
                 ncol=2, 
                 dimnames = list(list("Row 1", "Row 2"), 
                                 list("Column 1", "Column 2")))

  htmlTable(output)

  ###################################################################

  # Below saves all outputs to a list that
all_tables <- list()
htmlTable(output) ->
  all_tables[["Basic table"]]

# An advanced output
output <-
  matrix(ncol=6, nrow=8)
for (nr in 1:nrow(output)){
  for (nc in 1:ncol(output)){
    output[nr, nc] <-
      paste0(nr, ":", nc)
  }
}

output %>%
  addHtmlTableStyle(align="r",
    col.columns = c(rep("none", 2),
      rep("#F5FBFF", 4)),
    col.rgroup = c("none", "#F7F7F7"),
    css.cell = "padding-left: .5em; padding-right: .2em;")) %>%
htmlTable(header = paste(c("1st", "2nd",
    "3rd", "4th",
    "5th", "6th"),
    "hdr"),
  rnames = paste(c("1st", "2nd",
    "3rd",
    paste0(4:8, "th")),
    "row"),
  rgroup = paste("Group", LETTERS[1:3]),
  n.rgroup = c(2,4,nrow(output) - 6),
  cgroup = rbind(c("", "Column spanners", NA),
    c("", "Cgroup 1", "Cgroup 2"),
    c(1,2,NA),
    c(2,2,2)),
  caption="Basic table with both column spanners (groups) and row groups",
  cspan.rgroup = 2) ->
  all_tables[["Advanced table"]]

# An advanced empty table
suppressWarnings({
  matrix(ncol = 6,
    nrow = 0) %>%
    addHtmlTableStyle(col.columns = c(rep("none", 2),
      rep("#F5FBFF", 4)),
    col.rgroup = c("none", "#F7F7F7"),
getHtmlTableStyle

Get style options for object

Description

A wrap around the base::attr() that retrieves the style attribute used by htmlTable() (htmlTable.style).

Usage

getHtmlTableStyle(x)

Arguments

x The object intended for htmlTable().

Value

A list if the attribute exists, otherwise NULL.
getHtmlTableTheme

Examples

```r
library(magrittr)

mx <- matrix(1:4, ncol = 2)
colnames(mx) <- LETTERS[1:2]
mx %>%
  addHtmlTableStyle(align = "1|r") %>%
  getHtmlTableStyle()
```

getHtmlTableTheme

Retrieve the `htmlTable()` theme list

Description

A wrapper for a `getOption("htmlTable.theme")()` call that returns the standard theme unless one is set.

Usage

```r
getHtmlTableTheme()
```

Value

list with the styles to be applied to the table

Examples

```r
getHtmlTableTheme()
```

hasHtmlTableStyle

Check if object has a style set to it

Description

If the attribute `htmlTable.style` is set it will check if the `style_name` exists and return a logical.

Usage

```r
hasHtmlTableStyle(x, style_name)
```

Arguments

- **x**  
The object intended for `htmlTable()`.
- **style_name**  
A string that contains the style name.
Value

logical TRUE if the attribute and style is not NULL

See Also

Other htmlTableStyle: addHtmlTableStyle()

Examples

library(magrittr)

mx <- matrix(1:4, ncol = 2)
colnames(mx) <- LETTERS[1:2]
mx %>%
  addHtmlTableStyle(align = "l|r") %>%
  hasHtmlTableStyle("align")

htmlTable

Output an HTML table

Description

This is a function for outputting a more advanced tables using HTML. The core philosophy is to bring column and row groups into the table and allow for a dense representation of complex tables. The HTML-output is designed for maximum compatibility with copy-paste functionality into word-processors. For adding styles, see addHtmlTableStyle() and themes setHtmlTableTheme(). Note: If you are using tidyverse and dplyr you may want to check out tidyHtmlTable() that automates many of the arguments that htmlTable requires.

Usage

htmlTable(
  x,
  header = NULL,
  rnames = NULL,
  rowlabel = NULL,
  caption = NULL,
  tfoot = NULL,
  label = NULL,
  rgroup = NULL,
  n.rgroup = NULL,
  cgroup = NULL,
  n.cgroup = NULL,
  tspanner = NULL,
  n.tspanner = NULL,
  total = NULL,
  ctable = TRUE,
htmlTable

compatibility = getOption("htmlTableCompat", "LibreOffice"),

cspan.rgroup = "all",

escape.html = FALSE,

...)

## Default S3 method:
htmlTable(
  x,
  header = NULL,
  rnames = NULL,
  rowlabel = NULL,
  caption = NULL,
  tfoot = NULL,
  label = NULL,
  rgroup = NULL,
  n.rgroup = NULL,
  cgroup = NULL,
  n.cgroup = NULL,
  tspanner = NULL,
  n.tspanner = NULL,
  total = NULL,
  ctable = TRUE,
  compatibility = getOption("htmlTableCompat", "LibreOffice"),
  cspan.rgroup = "all",
  escape.html = FALSE,
  ...
)

## S3 method for class 'htmlTable'
knit_print(x, ...)

## S3 method for class 'htmlTable'
print(x, useViewer, ...)

Arguments

x          The matrix/data.frame with the data. For the print and knit_print it takes a string of the class htmlTable as x argument.

header     A vector of character strings specifying column header, defaulting to colnames(x)

rnames     Default row names are generated from rownames(x). If you provide FALSE then it will skip the row names. Note: For data.frames if you do rownames(my_dataframe) &lt;- NULL it still has row names. Thus you need to use FALSE if you want to supress row names for data.frames.

rowlabel   If the table has row names or rnames, rowlabel is a character string containing the column heading for the rnames.

caption    Adds a table caption.
tfoot  Adds a table footer (uses the <tfoot> HTML element). The output is run through txtMergeLines() simplifying the generation of multiple lines.

label   A text string representing a symbolic label for the table for referencing as an anchor. All you need to do is to reference the table, for instance <a href="#anchor_name">see table 2</a>. This is known as the element's id attribute, i.e. table id, in HTML linguo, and should be unique id for an HTML element in contrast to the css.class element attribute.

rgroup  A vector of character strings containing headings for row groups. n.rgroup must be present when rgroup is given. See detailed description in section below.

n.rgroup An integer vector giving the number of rows in each grouping. If rgroup is not specified, n.rgroup is just used to divide off blocks of rows by horizontal lines. If rgroup is given but n.rgroup is omitted, n.rgroup will default so that each row group contains the same number of rows. If you want additional rgroup column elements to the cells you can set the "add" attribute to rgroup through attr(rgroup,"add"), see below explaining section.

cgroup  A vector, matrix or list of character strings defining major column header. The default is to have none. These elements are also known as column spanners. If you want a column not to have a spanner then put that column as ".". If you pass cgroup and n.crgroup as matrices you can have column spanners for several rows. See cgroup section below for details.

n.cgroup An integer vector, matrix or list containing the number of columns for which each element in cgroup is a heading. For example, specify cgroup=c("Major_1","Major_2"), n.cgroup=c(3,3) if "Major_1" is to span columns 1-3 and "Major_2" is to span columns 4-6. rowlabel does not count in the column numbers. You can omit n.cgroup if all groups have the same number of columns. If the n.cgroup is one less than the number of columns in the matrix/data.frame then it automatically adds those.

tspanner The table spanner is somewhat of a table header that you can use when you want to join different tables with the same columns.

n.tspanner An integer vector with the number of rows or rgroups in the original matrix that the table spanner should span. If you have provided one fewer n.tspanner elements the last will be imputed from the number of rgroups (if you have provided rgroup and sum(n.tspanner) < length(rgroup)) or the number of rows in the table.

total  The last row is sometimes a row total with a border on top and bold fonts. Set this to TRUE if you are interested in such a row. If you want a total row at the end of each table spanner you can set this to "tspanner".

ctable  If the table should have a double top border or a single a’ la LaTeX ctable style

compatibility Is default set to LibreOffice as some settings need to be in old HTML format as Libre Office can’t handle some commands such as the css caption-alignment. Note: this option is not yet fully implemented for all details, in the future I aim to generate a HTML-correct table and one that is aimed at Libre Office compatibility. Word-compatibility is difficult as Word ignores most settings and destroys all layout attempts (at least that is how my 2010 version behaves). You can additinally use the options(htmlTableCompat = "html") if you want a change to apply to the entire document. MS Excel sometimes misinterprets
certain cell data when opening HTML-tables (e.g. 1/2 becomes 1. February).
To avoid this please specify the correct Microsoft Office format for each cell in
the table using the css.cell-argument. To make MS Excel interpret everything as
text use "mso-number-format:"@"".

**cspan.rgroup**

The number of columns that an rgroup should span. It spans by default all
columns but you may want to limit this if you have column colors that you want
to retain.

**escape.html**

logical: should HTML characters be escaped? Defaults to FALSE.

... Passed on to print.htmlTable function and any argument except the useViewer
 will be passed on to the base::cat() functions arguments. **Note:** as of version
2.0.0 styling options are still allowed but it is recommended to instead prepro-
cess your object with addHtmlTableStyle().

**useViewer**

If you are using RStudio there is a viewer that can render the table within that is
envoked if in base::interactive() mode. Set this to FALSE if you want to re-
move that functionality. You can also force the function to call a specific viewer
by setting this to a viewer function, e.g. useViewer = utils::browseURL if
you want to override the default RStudio viewer. Another option that does
the same is to set the options(viewer=utils::browseURL) and it will de-
fault to that particular viewer (this is how RStudio decides on a viewer). **Note:**
If you want to force all output to go through the base::cat() the set [op-
tions][base::options](htmlTable.cat = TRUE).

**Value**

string Returns a string of class htmlTable

---

**Multiple rows of column spanners** cgroup

If you want to have a column spanner in multiple levels you can set the cgroup and n.cgroup
arguments to a matrix or list.

If the different levels have different number of elements and you have provided a matrix you need to
set the ones that lack elements to NA. For instance cgroup = rbind(c("first","second",NA),c("a","b","c")).
And the corresponding n.cgroup would be n.cgroup = rbind(c(1,2,NA),c(2,1,2)). for a table
consisting of 5 columns. The "first" spans the first two columns, the "second" spans the last three
columns,"a" spans the first two, "b" the middle column, and "c" the last two columns.

It is recommended to use list as you will not have to bother with the NA.

If you want leave a cgroup empty then simply provide "" as the cgroup.

**The rgroup argument**

The rgroup allows you to smoothly group rows. Each row within a group receives an indention of
two blank spaces and are grouped with their corresponding rgroup element. The sum(n.rgroup)
should always be equal or less than the matrix rows. If less then it will pad the remaining rows
with either an empty rgroup, i.e. an "" or if the rgroup is one longer than the n.rgroup the last
n.rgroup element will be calculated through nrow(x) -sum(n.rgroup) in order to make the table
generating smoother.
The add attribute to rgroup

You can now have an additional element at the rgroup level by specifying the attr(rgroup, 'add'). The value can either be a vector, a list, or a matrix. See vignette("general", package = "htmlTable") for examples.

- A vector of either equal number of rgroups to the number of rgroups that aren’t empty, i.e. rgroup[rgroup != ""]. Or a named vector where the name must correspond to either an rgroup or to an rgroup number.
- A list that has exactly the same requirements as the vector. In addition to the previous we can also have a list with column numbers within as names within the list.
- A matrix with the dimension nrow(x) x ncol(x) or nrow(x) x 1 where the latter is equivalent to a named vector. If you have rownames these will resolve similarly to the names to the list/vector arguments. The same thing applies to colnames.

Important knitr-note

This function will only work with knitr outputting HTML, i.e. markdown mode. As the function returns raw HTML-code the compatibility with non-HTML formatting is limited, even with pandoc. Thanks to the the knitr::knit_print() and the knitr::asis_output() the results='asis' is no longer needed except within for-loops. If you have a knitr-chunk with a for loop and use print() to produce raw HTML you must set the chunk option results='asis'. Note: the print-function relies on the base::interactive() function for determining if the output should be sent to a browser or to the terminal. In vignettes and other directly knitted documents you may need to either set useViewer = FALSE alternatively set options(htmlTable.cat = TRUE).

RStudio’s notebook

RStudio has an interactive notebook that allows output directly into the document. In order for the output to be properly formatted it needs to have the class of html. The htmlTable tries to identify if the environment is a notebook document (uses the rstudioapi and identifies if its a file with a .Rmd file ending or if there is an element with html_notebook). If you don’t want this behavior you can remove it using the options(htmlTable.skip_notebook = TRUE).

Table counter

If you set the option table_counter you will get a Table 1,2,3 etc before each table, just set options(table_counter=TRUE). If you set it to a number then that number will correspond to the start of the table_counter. The table_counter option will also contain the number of the last table, this can be useful when referencing it in text. By setting the option options(table_counter_str = "<b>Table %s:</b> ") you can manipulate the counter table text that is added prior to the actual caption. Note, you should use the sprintf( ) %s instead of %d as the software converts all numbers to characters for compatibility reasons. If you set options(table_counter_roman = TRUE) then the table counter will use Roman numerals instead of Arabic.

Empty data frames

An empty data frame will result in a warning and output an empty table, provided that rgroup and n.rgroup are not specified. All other row layout options will be ignored.
Options

There are multiple options that can be set, here is a set of the perhaps most used:

- `table_counter` - logical - activates a counter for each table
- `table_counter_roman` - logical - if true the counter is in Roman numbers, i.e. I, II, III, IV...
- `table_counter_str` - string - the string used for generating the table counter text
- `useViewer` - logical - if viewer should be used for printing the table
- `htmlTable.cat` - logical - if the output should be directly sent to `cat()`
- `htmlTable.skip_notebook` - logical - skips the logic for detecting notebook
- `htmlTable.pretty_indentation` - logical - there was some issues in previous Pandoc versions where HTML indentation caused everything to be interpreted as code. This seems to be fixed and if you want to look at the raw HTML code it is nice to have this set to TRUE so that the tags and elements are properly indented.
- `htmlTableCompat` - string - see parameter description

Other

Copy-pasting: As you copy-paste results into Word you need to keep the original formatting. Either right click and choose that paste option or click on the icon appearing after a paste. Currently the following compatibilities have been tested with MS Word 2016:

- **Internet Explorer** (v. 11.20.10586.0) Works perfectly when copy-pasting into Word
- **RStudio** (v. 0.99.448) Works perfectly when copy-pasting into Word. *Note:* can have issues with multi-line cgroups - see bug
- **Chrome** (v. 47.0.2526.106) Works perfectly when copy-pasting into Word. *Note:* can have issues with multi-line cgroups - see bug
- **Firefox** (v. 43.0.3) Works poorly - looses font-styling, lines and general feel
- **Edge** (v. 25.10586.0.0) Works poorly - looses lines and general feel

Direct word processor opening: Opening directly in Libre Office or Word is no longer recommended. You get much prettier results using the cut-and-paste option.

Google docs: Copy-paste directly into a Google docs document is handled rather well. This seems to work especially well when the paste comes directly from a Chrome browser.

*Note* that when using complex cgroup alignments with multiple levels not every browser is able to handle this. For instance the RStudio webkit browser seems to have issues with this and a bug has been filed.

As the table uses HTML for rendering you need to be aware of that headers, row names, and cell values should try respect this for optimal display. Browsers try to compensate and frequently the tables still turn out fine but it is not advised. Most importantly you should try to use `<` instead of `&lt;` and `>` instead of `&gt;`. You can find a complete list of HTML characters here.

Lastly, I want to mention that function was inspired by the `Hmisc::latex()` that can be an excellent alternative if you wish to switch to PDF-output. For the sibling function `tidyHtmlTable()` you can directly switch between the two using the `table_fn` argument.

Examples

library(magrittr)

# Basic example
output <- matrix(1:4, 
                 ncol=2, 
                 dimnames = list(list("Row 1", "Row 2"), 
                                 list("Column 1", "Column 2")))

htmlTable(output)

# Below saves all outputs to a list that #
# it outputted all at once at the end      #
# this is mostly for allowing you to view #
# and evaluate each example section as    #
# they would otherwise be overwritten by   #
# eachother                               #

all_tables <- list()

htmlTable(output) ->
  all_tables[["Basic table"]]

# An advanced output
output <-
  matrix(ncol=6, nrow=8)

for (nr in 1:nrow(output)){
  for (nc in 1:ncol(output)){
    output[nr, nc] <-
      paste0(nr, ":", nc)
  }
}

output %>%
  addHtmlTableStyle(align="r",
                    col.columns = c(rep("none", 2),
                                   rep("#F5FBFF", 4)),
                    col.rgroup = c("none", "#F7F7F7"),
                    css.cell = "padding-left:.5em; padding-right:.2em;") %>%

                                    nrow=nrow(simple_output)))) %>%
  htmlTable(header = LETTERS[1:2]) ->
all_tables["Header formatting"]

concatHtmlTables(all_tables)

# See vignette("tables", package = "htmlTable")
# for more examples
Description

This widget renders a table with pagination into an htmlwidget.

Usage

```r
htmlTableWidget(
  x,
  number_of_entries = c(10, 25, 100),
  width = NULL,
  height = NULL,
  elementId = NULL,
  ...
)
```

Arguments

- `x`: A data frame to be rendered
- `number_of_entries`: A numeric vector with the number of entries per page to show. If there is more than one number given, the user will be able to show the number of rows per page in the table.
- `width`: Fixed width for widget (in css units). The default is `NULL`, which results in intelligent automatic sizing based on the widget's container.
- `height`: Fixed height for widget (in css units). The default is `NULL`, which results in intelligent automatic sizing based on the widget's container.
- `elementId`: Use an explicit element ID for the widget (rather than an automatically generated one). Useful if you have other JavaScript that needs to explicitly discover and interact with a specific widget instance.
- `...`: Additional parameters passed to `htmlTable`

Value

- an htmlwidget showing the paginated table

---

**htmlTableWidget-shiny**  
*Shiny bindings for htmlTableWidget*

Description

Output and render functions for using `htmlTableWidget` within Shiny applications and interactive Rmd documents.

Usage

```r
htmlTableWidgetOutput(outputId, width = "100\%", height = "400px")

renderHtmlTableWidget(expr, env = parent.frame(), quoted = FALSE)
```
innerJoinByCommonCols

Arguments

- outputId  output variable to read from
- width, height  Must be a valid CSS unit (like '100%', '400px', 'auto') or a number, which will be coerced to a string and have 'px' appended.
- expr  An expression that generates a htmlTableWidget()
- env  The environment in which to evaluate expr.
- quoted  Is expr a quoted expression (with quote())? This is useful if you want to save an expression in a variable.

Examples

```r
## Not run:
# In the UI:
htmlTableWidgetOutput("mywidget")
# In the server:
renderHtmlTableWidget({
  htmlTableWidget(iris)
})
## End(Not run)
```

innerJoinByCommonCols  A simple function for joining two tables by their intersected columns

Description

A simple function for joining two tables by their intersected columns

Usage

innerJoinByCommonCols(x, y)

Arguments

- x  data.frame
- y  data.frame

Value

data.frame
interactiveTable

An interactive table that allows you to limit the size of boxes

Description

This function wraps the htmlTable and adds JavaScript code for toggling the amount of text shown in any particular cell.

Usage

interactiveTable(
  x,
  ..., 
  txt.maxlen = 20,
  button = getOption("htmlTable.interactiveTable.button", default = FALSE),
  minimized.columns,
  js.scripts = c()
)

## S3 method for class 'htmlTable'
interactiveTable(
  tbl,
  txt.maxlen = 20,
  button = getOption("htmlTable.interactiveTable.button", default = FALSE),
  minimized.columns = NULL,
  js.scripts = c()
)

## S3 method for class 'interactiveTable'
knit_print(x, ...)

## S3 method for class 'interactiveTable'
print(x, useViewer, ...)

Arguments

x
  The interactive table that is to be printed
...
  The exact same parameters as htmlTable() uses
txt.maxlen
  The maximum length of a text
button
  Indicator if the cell should be clickable or if a button should appear with a plus/minus
minimized.columns
  Notifies if any particular columns should be collapsed from start
js.scripts
  If you want to add your own JavaScript code you can just add it here. All code is merged into one string where each section is wrapped in it’s own <script></script> element.
An htmlTable object can be directly passed into the function

If you are using RStudio there is a viewer that can render the table within that is
envoked if in `base::interactive()` mode. Set this to FALSE if you want to re-
move that functionality. You can also force the function to call a specific viewer
by setting this to a viewer function, e.g. `useViewer = utils::browseURL` if
you want to override the default RStudio viewer. Another option that does
the same is to set the options(viewer=utils::browseURL) and it will de-
fault to that particular viewer (this is how RStudio decides on a viewer). Note:
If you want to force all output to go through the `base::cat()` the set [op-
tions][base::options(htmlTable.cat = TRUE).

Value

An htmlTable with a javascript attribute containing the code that is then printed

Examples

```r
library(magrittr)
# A simple output
long_txt <- "Lorem ipsum dolor sit amet, consectetur adipiscing elit,
  sed do eiusmod tempor incididunt ut labore et dolore magna aliqua.
  Ut enim ad minim veniam, quis nostrud exercitation ullamco laboris nisi
  ut aliquip ex ea commodo consequat. Duis aute irure dolor in reprehenderit
  in voluptate velit esse cillum dolore eu fugiat nulla pariatur. Excepteur
  sint occaecat cupidatat non proident, sunt in culpa qui officia deserunt
  mollit anim id est laborum"
short_txt <- gsub("([\^\.]+)\.*", "\1", long_txt)
cbind(rep(short_txt, 2),
  rep(long_txt, 2)) %>%
  addHtmlTableStyle(col.rgroup = c("#FFF", "#EEF")) %>%
  interactiveTable(minimized.columns = ncol(.),
                  header = c("Short", "Long"),
                  rnames = c("First", "Second"))
```

---

**prBindDataListIntoColumns**

*Merge columns into a tibble*

**Description**

Almost the same as `tibble::tibble()` but it solves the issue with some of the arguments being
columns and some just being vectors.

**Usage**

`prBindDataListIntoColumns(dataList)`
Arguments
dataList list with the columns/data.frames

Value
data.frame object

prConvertDfFactors

Convert all factors to characters to print them as they expected

Description

Convert all factors to characters to print them as they expected

Usage

prConvertDfFactors(x)

Arguments

x The matrix/data.frame with the data. For the print and knitr.print it takes a string of the class htmlTable as x argument.

Value

The data frame with factors as characters

prepGroupCounts

Retrieves counts for rgroup, cgroup, & tspanner arguments

Description

This function is a wrapper to base::rle() that does exactly this but is a little too picky about input values.

Usage

prepGroupCounts(x)

Arguments

x The vector to process

Value

list(n = rle$lengths, names = rle$values)
**prEscapeHtml**

### Examples

```r
prepGroupCounts(c(1:3, 3:1))
```

---

**Remove html entities from table**

### Description

Removes the htmlEntities from table input data. Note that this also replaces $ signs in order to remove the MathJax issue.

### Usage

```r
prEscapeHtml(x)
```

### Arguments

- **x**: The matrix/data.frame with the data. For the print and knit_print it takes a string of the class htmlTable as x argument.

### Value

x without the html entities

### See Also

Other hidden helper functions for htmlTable: `prAddCells()`, `prAddEmptySpacerCell()`, `prAddSemicolon2StrEnd()`, `prGetCgroupHeader()`, `prGetRowlabelPos()`, `prGetStyle()`, `prPrepInputMatrixDimensions()`, `prPrepareAlign()`, `prPrepareCgroup()`, `prTblNo()`

---

**prExtractElementsAndConvertToTbl**

*Extract the elements and generate a table with unique elements*

### Description

Extract the elements and generate a table with unique elements

### Usage

```r
prExtractElementsAndConvertToTbl(x, elements)
```

### Arguments

- **x**: list with columns to be joined
- **elements**: char vector with the elements to select
Description

For the vignettes there is a dataset downloaded by using the `get_pxweb_data()` call. The data is from SCB (Statistics Sweden) and downloaded using the `pxweb` package:

Author(s)

Max Gordon <max@gforge.se>

References

https://scb.se

Examples

```r
## Not run:
# The data was generated through downloading via the API
library(pxweb)

# Get the last 15 years of data (the data always lags 1 year)
current_year <- as.integer(format(Sys.Date(), "%Y")) -1
SCB <- get_pxweb_data(
  dims = list(Region = c(00, 01, 03, 25),
              Kon = c(1, 2),
              ContentsCode = c(BE0101G9),
              Tid = (current_year-14):current_year),
  clean = TRUE)

# Some cleaning was needed before use
SCB$region <- factor(substring(as.character(SCB$region), 4))
Swe_ltrs <- c("å" = "&aring;",
              "Å" = "&Aring;",
              "ä" = "&aelig;",
              "Ä" = "&AElig;",
              "ö" = "&ouml;",
              "Ö" = "&Ouml;")
for (i in 1:length(Swe_ltrs)) {
  levels(SCB$region) <- gsub(names(Swe_ltrs)[i],
                            Swe_ltrs[i],
                            levels(SCB$region))
}

save(SCB, file = "data/SCB.rda")

## End(Not run)
```
setHtmlTableTheme

Set or update theme for htmlTable()

Description

The theme guides many of the non-data objects visual appearance. The theme can be over-ridden by settings for each table. To get a more complete understanding of the options, see addHtmlTableStyle().

Usage

setHtmlTableTheme(
  theme = NULL,
  align = NULL,
  align.header = NULL,
  align.cgroup = NULL,
  css.rgroup = NULL,
  css.rgroup.sep = NULL,
  css.tspanner = NULL,
  css.tspanner.sep = NULL,
  css.total = NULL,
  css.cell = NULL,
  css.cgroup = NULL,
  css.header = NULL,
  css.header.border_bottom = NULL,
  css.class = NULL,
  css.table = NULL,
  pos.rowlabel = NULL,
  pos.caption = NULL,
  col.rgroup = NULL,
  col.columns = NULL,
  padding.rgroup = NULL,
  padding.tspanner = NULL,
  spacer.celltype = NULL,
  spacer.css.cgroup.bottom.border = NULL,
  spacer.css = NULL,
  spacer.content = NULL
)

Arguments

theme A list containing all the styles or a string that is matched to some of the preset style (See details below in the Theme options section). Note: the full name of the theme is not required as they are matched using base::match.arg().

align A character strings specifying column alignments, defaulting to 'c' to center. Valid chars for alignments are l = left, c = center and r = right. You can also specify align='c|c' and other LaTeX tabular formatting. If you want to set
the alignment of the rownames this string needst to be ncol(x) + 1, otherwise it automatically pads the string with a left alignment for the rownames.

align.header A character strings specifying alignment for column header, defaulting to centered, i.e. \texttt{[paste][base::paste](rep('c',ncol(x)),collapse='')}.

align.cgroup The justification of the cgroups

css.rgroup CSS style for the rgroup, if different styles are wanted for each of the rgroups you can just specify a vector with the number of elements.

css.rgroup.sep The line between different rgroups. The line is set to the TR element of the lower rgroup, i.e. you have to set the border-top/padding-top etc to a line with the expected function. This is only used for rgroups that are printed. You can specify different separators if you give a vector of rgroup - 1 length (this is since the first rgroup doesn’t have a separator).

css.tspanner The CSS style for the table spanner.

css.tspanner.sep The line between different spanners.

css.total The css of the total row if such is activated.

css.cell The css.cell element allows you to add any possible CSS style to your table cells. See section below for details.

css.cgroup The same as css.class but for cgroup formatting.

css.header The header style, not including the cgroup style

css.header.border_bottom The header bottom-border style, e.g. border-bottom: 1px solid grey

css.class The html CSS class for the table. This allows directing html formatting through CSS directly at all instances of that class. \textit{Note:} unfortunately the CSS is frequently ignored by word processors. This option is mostly intended for web-presentations.

css.table You can specify the the style of the table-element using this parameter

pos.rowlabel Where the rowlabel should be positioned. This value can be "top", "bottom", "header", or a integer between 1 and nrow(cgroup) + 1. The options "bottom" and "header" are the same, where the row label is presented at the same level as the header.

pos.caption Set to "bottom" to position a caption below the table instead of the default of "top".

col.rgroup Alternating colors (zebra striping/banded rows) for each rgroup; one or two colors is recommended and will be recycled.

col.columns Alternating colors for each column.

padding.rgroup Generally two non-breakings spaces, i.e. \\&nbsp;&nbsp;, but some journals only have a bold face for the rgroup and leaves the subelements unindented.

padding.tspanner The table spanner is usually without padding but you may specify padding similar to padding.rgroup and it will be added to all elements, including the rgroup elements. This allows for a 3-level hierarchy if needed.
**setHtmlTableTheme**

**spacer.celltype**

When using cgroup the table headers are separated through an empty HTML cell that is by default filled with &nbsp; (no-breaking-space) that prevents the cell from collapsing. The purpose of this is to prevent the headers underline to bleed into one as the underline is for the entire cell. You can alter this behavior by changing this option, valid options are `single_empty`, `skip`, `double_cell`. The `single_empty` is the default, the `skip` lets the header bleed into one and skips entirely, `double_cell` is for having two cells so that a vertical border ends up centered (specified using the align option). The arguments are matched internally using `base::match.arg` so you can specify only a part of the name, e.g. "sk" will match "skip".

**spacer.css.cgroup.bottom.border**

Defaults to none and used for separating cgroup headers. Due to a browser bug this is sometimes ignored and you may therefore need to set this to 1px solid white to enforce a white border.

**spacer.css**

If you want the spacer cells to share settings you can set it here

**spacer.content**

Defaults to &nbsp; as this guarantees that the cell is not collapsed and is highly compatible when copy-pasting to word processors.

**Value**

An invisible list with the new theme

**Theme options**

The styles available are:

- **standard**: The traditional standard style used in `htmlTable()` since the early days
- **Google docs**: A style that is optimized for copy-pasting into documents on Google drive. This is geared towards minimal padding and margins so that the table is as dense as possible.
- **blank**: Just as the name suggests the style is completely empty in terms of CSS. Positions for rowlabel and caption are set to bottom as these cannot be blank.

You can also provide your own style. Each style should be a names vector, e.g. `c(width = "100px",color = "red")` or just a real css string, `width: 100px; color: red;`.

**Examples**

```r
# Not run:
setHtmlTableTheme("Google", align = "r")
```

```r
# End(Not run)
```
**tblNoLast**  
*Gets the last table number*

**Description**

The function relies on `options("table_counter")` in order to keep track of the last number.

**Usage**

```
tblNoLast(roman = getOption("table_counter_roman", FALSE))
```

**Arguments**

- **roman**
  
  Whether or not to use roman numbers instead of arabic. Can also be set through `options(table_caption_no_roman = TRUE)`

**See Also**

Other table functions: `htmlTable`, `tblNoNext()`

**Examples**

```
org_opts <- options(table_counter=1)
tblNoLast()
options(org_opts)
```

---

**tblNoNext**  
*Gets the next table number*

**Description**

The function relies on `options("table_counter")` in order to keep track of the last number.

**Usage**

```
tblNoNext(roman = getOption("table_counter_roman", FALSE))
```

**Arguments**

- **roman**
  
  Whether or not to use roman numbers instead of arabic. Can also be set through `options(table_caption_no_roman = TRUE)`

**See Also**

Other table functions: `htmlTable`, `tblNoLast()`
 tidyHtmlTable

Examples

```r
org_opts <- options(table_counter=1)
tblNoNext()
options(org_opts)
```

 tidyHtmlTable Generate an htmlTable using tidy data as input

Description

Builds an htmlTable by mapping columns from the input data, x, to elements of an output htmlTable (e.g. rnames, header, etc.). This provides a ggplot2-like interface you can pivot rows/columns as required. The typical use case is when you are using dplyr together with the tidyverse data processing functions, see vignette("tidyHtmlTable").

Usage

```r
tidyHtmlTable(
  x,  
  value, 
  header, 
  rnames, 
  rgroup, 
  hidden_rgroup, 
  cgroup, 
  tspanner, 
  hidden_tspanner, 
  skip_removal_warning = getOption("htmlTable.skip_removal_warning", FALSE), 
  rnames_unique, 
  table_fn = htmlTable, 
  ...
)
```

Arguments

- **x** Tidy data used to build the htmlTable
- **value** The column containing values filling individual cells of the output htmlTable. Defaults to "value" as used by `tidyr::pivot_longer()`.
- **header** The column in x specifying column headings
- **rnames** The column in x specifying row names. Defaults to "name" as used by `tidyr::pivot_longer()`.
- **rgroup** The column in x specifying row groups
- **hidden_rgroup** strings with rgroup values that will be hidden (the values will still be there but the spanner will be set to "" and thus ignored by `htmlTable()`).
- **cgroup** The column or columns in x specifying the column groups
- **tspanner** The column in x specifying tspanner groups
hidden_tspanner

- strings with tspanner values that will be hidden (the values will still be there but the spanner will be set to "" and thus ignored by `htmlTable()`).

skip_removal_warning

- boolean suppress warning message when removing NA columns.

rnames_unique

- Similar to rnames where we have issues with the uniqueness of a row as selected by the select statement. See section below on Row uniqueness.

table_fn

- The table function that should receive the input, defaults to `htmlTable()` but you can provide any function that uses the same input formatting. This package was inspired by the `Hmisc::latex()` function.

... Additional arguments that will be passed to the inner `htmlTable()` function.

### Value

Returns html code that will build a pretty table.

### Column-mapping parameters

The `tidyHtmlTable` function is designed to work like ggplot2 in that columns from `x` are mapped to specific parameters from the `htmlTable` function. At minimum, `x` must contain the names of columns mapping to `rnames`, `header`, and `rnames`. `header` and `rnames` retain the same meaning as in the `htmlTable` function. `value` contains the individual values that will be used to fill each cell within the output `htmlTable`.

A full list of parameters from `htmlTable` which may be mapped to columns within `x` include:

- `value`
- `header`
- `rnames`
- `rgroup`
- `cgroup`
- `tspanner`

Also note that the coordinates of each `value` within `x` must be unambiguously mapped to a position within the output `htmlTable`. Therefore, the each row-wise combination the variables specified above contained in `x` must be unique.

### Sorting

Sorting of rows is as of version 2.0 skipped as we may have situations with repeating inputs and this can easily be performed pre-function by calling `dplyr::arrange()` prior to `tidyHtmlTable`.

Columns are sorted by `arrange(cgroup,header)` where `cgroup` will be expanded to the columns of the `cgroup` argument, e.g. `cgroup = c(a, b)`, `header = c` will become `arrange(a,b,c)`. If you want to sort in non-alphabetic order you can provide a factor variable and that information will be retained.
Hidden values

htmlTable Allows for some values within rgroup, cgroup, etc. to be specified as "". The following parameters allow for specific values to be treated as if they were a string of length zero in the htmlTable function.

- hidden_rgroup
- hidden_tspanner

Simple tibble output

The tibble discourages the use of row names. There is therefore a convenience option for tidyHtmlTable where you can use the function just as you would with htmlTable() where rnames is populated with the rnames argument provided using tidyselect syntax (defaults to the "names" column if present int the input data).

Additional dependencies

In order to run this function you also must have dplyr, tidyr, tidyselect and purrr packages installed. These have been removed due to the additional 20 Mb that these dependencies added (issue #47). *Note:* if you use tidyverse it will already have all of these and you do not need to worry.

Row uniqueness

Usually each row should have a unique combination of rnames, header, crgroup, ... Sometimes though rows come in a distinct order and the order identifies the row more than the name. If we are identifying bone fractures using the AO-classification we will have classes ranging in the form of:

- A
- A1
- A1.1
- A2
- A2.1
- A2.2
- B
- ...

we could therefore like to simplify the names to:

- A
- .1
- ...1
- .2
- ...1
- ...2
- B
And still retain the ability to follow what row corresponds to a given class. To do this you need to provide the original unique name in the parameter `rnames_unique` as `tidyHtmlTable` otherwise will merge rows not intended for merging.

Note it is recommended that you verify with the full names just to make sure that any unexpected row order change has happened in the underlying pivot functions.

```
txtMergeLines

Description

English uses ',' between every 3 numbers while the SI format recommends a ' ' if \( x > 10^4 \). The scientific form \( 10e+? \) is furthermore avoided.

Usage

txtInt(x, language = "en", html = TRUE, ...)

Arguments

- \( x \) The integer variable
- \( \text{language} \) The ISO-639-1 two-letter code for the language of interest. Currently only English is distinguished from the ISO format using a ',' as the separator.
- \( \text{html} \) If the format is used in HTML context then the space should be a non-breaking space, &nbsp;
- ... Passed to base::format()

Value

string

See Also

Other text formatters: txtMergeLines(), txtPval(), txtRound()

Examples

txtInt(123)

# Supplying a matrix
txtInt(matrix(c(1234, 12345, 123456, 1234567), ncol = 2))

# Missing are returned as empty strings, i.e. ""
txtInt(c(NA, 1e7))

________________________________________________________________________

txtMergeLines A merges lines while preserving the line break for HTML/LaTeX

________________________________________________________________________

Description

This function helps you to do a table header with multiple lines in both HTML and in LaTeX. In HTML this isn’t that tricky, you just use the <br /> command but in LaTeX I often find myself writing vbox/hbox stuff and therefore I’ve created this simple helper function.

Usage

txtMergeLines(..., html = 5)
Arguments

... The lines that you want to be joined
html If HTML compatible output should be used. If FALSE it outputs LaTeX formatting. Note if you set this to 5 then the HTML5 version of \texttt{br} will be used: \texttt{<br>} otherwise it uses the \texttt{<br />} that is compatible with the XHTML-formatting.

Value

string

See Also

Other text formatters: \texttt{txtInt()}, \texttt{txtPval()}, \texttt{txtRound()}

Examples

\begin{verbatim}
txtMergeLines("hello", "world")
txtMergeLines("hello", "world", html=FALSE)
txtMergeLines("hello", "world", list("A list", "is OK"))
\end{verbatim}

---

\texttt{txtPval} \begin{itemize}
\item \texttt{Formats the p-values}
\end{itemize}

Description

Gets formatted p-values. For instance you often want 0.1234 to be 0.12 while also having two values up until a limit, i.e. 0.01234 should be 0.012 while 0.001234 should be 0.001. Furthermore you want to have < 0.001 as it becomes ridiculous to report anything below that value.

Usage

\begin{verbatim}
txtPval(pvalues, lim.2dec = 10^-2, lim.sig = 10^-4, html = TRUE, ...)
\end{verbatim}

Arguments

\begin{itemize}
\item pvalues The p-values
\item lim.2dec The limit for showing two decimals. E.g. the p-value may be 0.056 and we may want to keep the two decimals in order to emphasize the proximity to the all-mighty 0.05 p-value and set this to 10^-2. This allows that a value of 0.0056 is rounded to 0.006 and this makes intuitive sense as the 0.0056 level as this is well below the 0.05 value and thus not as interesting to know the exact proximity to 0.05. \textit{Disclaimer:} The 0.05-limit is really silly and debated, unfortunately it remains a standard and this package tries to adapt to the current standards in order to limit publication associated issues.
\item lim.sig The significance limit for the less than sign, i.e. the '<'
\item html If the less than sign should be < or &lt; as needed for HTML output.
\item ... Currently only used for generating warnings of deprecated call parameters.
\end{itemize}
txtRound

Value

vector

See Also

Other text formatters: txtInt(), txtMergeLines(), txtRound()

Examples

txtPval(c(0.10234, 0.010234, 0.0010234, 0.000010234))

---

txtRound

A convenient rounding function

Description

If you provide a string value in X the function will try to round this if a numeric text is present. If
you want to skip certain rows/columns then use the excl.* arguments.

Usage

txtRound(x, ...)

## Default S3 method:
txtRound(
  x,
  digits = 0,
  digits.nonzero = NA,
  txt.NA = "",
  dec = getOption("htmlTable.decimal_marker", default = "."),
  scientific = NULL,
  txtInt_args = getOption("htmlTable.round_int", default = NULL),
  ...
)

## S3 method for class 'quotesingle.Var'
txtRound(x, ...)

## S3 method for class 'data.frame'
txtRound(x, ...)

## S3 method for class 'table'
txtRound(x, ...)

## S3 method for class 'matrix'
txtRound(x, digits = 0, excl.cols = NULL, excl.rows = NULL, ...)
Arguments

x The value/vector/data.frame/matrix to be rounded
...
Passed to next method
digits The number of digits to round each element to. If you provide a vector each
element will apply to the corresponding columns.
digits.nonzero The number of digits to keep if the result is close to zero. Sometimes we have
an entire table with large numbers only to have a few but interesting observation
that are really interesting
txt.NA The string to exchange NA with
dec The decimal marker. If the text is in non-English decimal and string formatted
you need to change this to the appropriate decimal indicator. The option for this is htmlTable.decimal_marker.
scientific If the value should be in scientific format.
txtInt_args A list of arguments to pass to txtInt() if that is to be used for large values that
may require a thousands separator. The option for this is htmlTable.round_int.
excl.cols Columns to exclude from the rounding procedure. This can be either a number
or regular expression. Skipped if x is a vector.
excl.rows Rows to exclude from the rounding procedure. This can be either a number or
regular expression.

Value

matrix/data.frame

See Also

Other text formatters: txtInt(), txtMergeLines(), txtPval()

Examples

mx <- matrix(c(1, 1.11, 1.25,
               2.50, 2.55, 2.45,
               3.2313, 3, pi),
              ncol = 3, byrow=TRUE)
txtRound(mx, 1)

---

vector2string Collapse vector to string

Description

Merges all the values and outputs a string formatted as ’1st element’, ’2nd element’, ...
vector2string

Usage

vector2string(
    x,
    quotation_mark = "",
    collapse = sprintf("%s, %s", quotation_mark, quotation_mark)
)

Arguments

x The vector to collapse
quotation_mark The type of quote to use
collapse The string that separates each element

Value

A string with ',' separation

Examples

vector2string(1:4)
vector2string(c("a", "b'b", "c"))
vector2string(c("a", "b'b", "c"), quotation_mark = "")
