Package ‘konfound’

June 1, 2021

Type  Package
Title  Quantify the Robustness of Causal Inferences
Version  0.4.0
Description  Statistical methods that quantify the conditions necessary to alter
inferences, also known as sensitivity analysis, are becoming increasingly
important to a variety of quantitative sciences. A series of recent works,
(2013) <doi:10.3102/0162373713493129> extend previous sensitivity analyses
by considering the characteristics of omitted variables or unobserved cases
that would change an inference if such variables or cases were observed. These
analyses generate statements such as ”an omitted variable would have to be
correlated at xx with the predictor of interest (e.g., treatment) and outcome
to invalidate an inference of a treatment effect”. Or ”one would have to replace
pp percent of the observed data with null hypothesis cases to invalidate the
inference”. We implement these recent developments of sensitivity analysis and
provide modules to calculate these two robustness indices and generate such
statements in R. In particular, the functions konfound(), pkonfound() and
mkonfound() allow users to calculate the robustness of inferences for a user’s
own model, a single published study and multiple studies respectively.

Index

<table>
<thead>
<tr>
<th>binary_dummy_data</th>
<th>Binary dummy data</th>
</tr>
</thead>
</table>

Description

This data is made-up data for use in examples.

Format

A data.frame with 107 rows and 2 variables.

<table>
<thead>
<tr>
<th>concord1</th>
<th>Concord1 data</th>
</tr>
</thead>
</table>

Description

This data is from Hamilton (1983)

Format

A data.frame with 496 rows and 10 variables.

References

konfound

Perform sensitivity analysis on fitted models

Description

For fitted models, this command calculates (1) how much bias there must be in an estimate to invalidate/sustain an inference; (2) the impact of an omitted variable necessary to invalidate/sustain an inference for a regression coefficient. Currently works for: models created with lm() (linear models).

Usage

konfound(
  model_object,
  tested_variable,
  alpha = 0.05,
  tails = 2,
  index = "RIR",
  to_return = "print",
  test_all = FALSE,
  two_by_two = FALSE,
  n_treat = NULL,
  switch_trm = TRUE,
  replace = "control"
)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>model_object</td>
<td>output from a model (currently works for: lm)</td>
</tr>
<tr>
<td>tested_variable</td>
<td>Variable associated with the unstandardized beta coefficient to be tested</td>
</tr>
<tr>
<td>alpha</td>
<td>probability of rejecting the null hypothesis (defaults to 0.05)</td>
</tr>
<tr>
<td>tails</td>
<td>integer whether hypothesis testing is one-tailed (1) or two-tailed (2; defaults to 2)</td>
</tr>
<tr>
<td>index</td>
<td>whether output is RIR or IT (impact threshold); defaults to &quot;RIR&quot;</td>
</tr>
<tr>
<td>to_return</td>
<td>whether to return a data.frame (by specifying this argument to equal &quot;raw_output&quot; for use in other analyses) or a plot (&quot;plot&quot;); default is to print (&quot;print&quot;) the output to the console; can specify a vector of output to return</td>
</tr>
<tr>
<td>test_all</td>
<td>whether to carry out the sensitivity test for all of the coefficients (defaults to FALSE)</td>
</tr>
</tbody>
</table>
two_by_two  whether or not the tested variable is a dichotomous variable in a GLM; if so, the 2X2 table approach is used; only works for single variables at present (so test_all = TRUE will return an error)
n_treat  the number of cases associated with the treatment condition; applicable only when model_type = "logistic"
switch_trm  whether to switch the treatment and control cases; defaults to FALSE; applicable only when model_type = "logistic"
replace  whether using entire sample or the control group to calculate the base rate; default is the entire sample

Value
prints the bias and the number of cases that would have to be replaced with cases for which there is no effect to invalidate the inference

Examples

# using lm() for linear models
m1 <- lm(mpg ~ wt + hp, data = mtcars)
konfound(m1, wt)
konfound(m1, wt, test_all = TRUE)
konfound(m1, wt, to_return = "table")

# using glm() for non-linear models
if (requireNamespace("forcats")) {
  d <- forcats::gss_cat
  d$married <- ifelse(d$marital == "Married", 1, 0)

  m2 <- glm(married ~ age, data = d, family = binomial(link = "logit"))
  konfound(m2, age)
}

# using lme4 for mixed effects (or multi-level) models
if (requireNamespace("lme4")) {
  library(lme4)
  m3 <- fm1 <- lme4::lmer(Reaction ~ Days + (1 | Subject), sleepstudy)
  konfound(m3, Days)
}

m4 <- glm(outcome ~ condition, data = binary_dummy_data, family = binomial(link = "logit"))
konfound(m4, condition, two_by_two = TRUE, n_treat = 55)

launch_shiny  Open interactive web application for konfound
**Description**

Open interactive web application for konfound

**Usage**

`launch_shiny()`

**Details**

Open the Shiny interactive web application in a browser

**Value**

Launches a web browser

---

**mkonfound**

*Perform meta-analyses including sensitivity analysis*

**Description**

For fitted models, this command carries out sensitivity analysis for a number of models, when their parameters stored in a data.frame.

**Usage**

`mkonfound(d, t, df, alpha = 0.05, tails = 2, return_plot = FALSE)`

**Arguments**

- `d` data.frame or tibble with the t-statistics and associated degrees of freedom
- `t` t-statistic or vector of t-statistics
- `df` degrees of freedom or vector of degrees of freedom associated with the t-statistics in the t argument
- `alpha` probability of rejecting the null hypothesis (defaults to 0.05)
- `tails` integer whether hypothesis testing is one-tailed (1) or two-tailed (2; defaults to 2)
- `return_plot` whether to return a plot of the percent bias; defaults to FALSE

**Value**

prints the bias and the number of cases that would have to be replaced with cases for which there is no effect to invalidate the inference for each of the cases in the data.frame
Examples

```r
## Not run:
mkonfound_ex
str(d)
mkonfound(mkonfound_ex, t, df)
## End(Not run)
```

### mkonfound_ex

Example data for the mkonfound function

#### Description

A dataset containing t and df values from example studies from Educational Evaluation and Policy Analysis (as detailed in Frank et al., 2013): https://drive.google.com/file/d/1aGhxGjvMvEPVAgOA8rrxvA97uU05TTMe/view

#### Usage

```r
mkonfound_ex
```

#### Format

A data frame with 30 rows and 2 variables:

- **t**: t value
- **df**: degrees of freedom associated with the t value ...

#### Source

https://drive.google.com/file/d/1aGhxGjvMvEPVAgOA8rrxvA97uU05TTMe/view

### pkonfound

Perform sensitivity analysis for published studies

#### Description

For published studies, this command calculates (1) how much bias there must be in an estimate to invalidate/sustain an inference; (2) the impact of an omitted variable necessary to invalidate/sustain an inference for a regression coefficient.
Usage

pkonfound(
  est_eff,
  std_err,
  n_obs,
  n_covariates = 1,
  alpha = 0.05,
  tails = 2,
  index = "RIR",
  nu = 0,
  n_treat = NULL,
  switch_trm = TRUE,
  model_type = "ols",
  a = NULL,
  b = NULL,
  c = NULL,
  d = NULL,
  two_by_two_table = NULL,
  test = "fisher",
  replace = "control",
  to_return = "print"
)

Arguments

est_eff the estimated effect (such as an unstandardized beta coefficient or a group mean difference)
std_err the standard error of the estimate of the unstandardized regression coefficient
n_obs the number of observations in the sample
n_covariates the number of covariates in the regression model
alpha probability of rejecting the null hypothesis (defaults to 0.05)
tails integer whether hypothesis testing is one-tailed (1) or two-tailed (2; defaults to 2)
index whether output is RIR or IT (impact threshold); defaults to "RIR"
nu what hypothesis to be tested; defaults to testing whether est_eff is significantly different from 0
n_treat the number of cases associated with the treatment condition; applicable only when model_type = "logistic"
switch_trm whether to switch the treatment and control cases; defaults to FALSE; applicable only when model_type = "logistic"
model_type the type of model being estimated; defaults to "ols" for a linear regression model; the other option is "logistic"
a cell is the number of cases in the control group showing unsuccessful results
b cell is the number of cases in the control group showing successful results
c cell is the number of cases in the treatment group showing unsuccessful results
d cell is the number of cases in the treatment group showing successful results
two_by_two_table table that is a matrix or can be coerced to one (data.frame, tibble, tribble) from which the a, b, c, and d arguments can be extracted
test whether using Fisher’s Exact Test or A chi-square test; defaults to Fisher’s Exact Test
replace whether using entire sample or the control group to calculate the base rate; default is the entire sample
to_return whether to return a data.frame (by specifying this argument to equal "raw_output" for use in other analyses) or a plot ("plot"); default is to print ("print") the output to the console; can specify a vector of output to return

Value

prints the bias and the number of cases that would have to be replaced with cases for which there is no effect to invalidate the inference

Examples

# using pkonfound for linear models
pkonfound(2, .4, 100, 3)
pkonfound(-2.2, .65, 200, 3)
pkonfound(.5, 3, 200, 3)
pkonfound(-0.2, 0.103, 20888, 3, n_treat = 17888, model_type = "logistic")

pkonfound(2, .4, 100, 3, to_return = "thresh_plot")
pkonfound(2, .4, 100, 3, to_return = "corr_plot")

pkonfound_output <- pkonfound(2, .4, 200, 3,
 to_return = c("raw_output", "thresh_plot", "corr_plot")
 )
summary(pkonfound_output)
pkonfound_output$raw_output
pkonfound_output$thresh_plot
pkonfound_output$corr_plot

# using pkonfound for a 2x2 table
pkonfound(a = 35, b = 17, c = 17, d = 38)
pkonfound(a = 35, b = 17, c = 17, d = 38, alpha = 0.01)
pkonfound(a = 35, b = 17, c = 17, d = 38, alpha = 0.01, switch_trm = FALSE)
pkonfound(a = 35, b = 17, c = 17, d = 38, test = "chisq")
summary.konfound

Concise summary of konfound output

Description
Concise summary of konfound output

Usage

```r
## S3 method for class 'konfound'
summary(object, ...)
```

Arguments

- `object` A `konfound` object
- `...` Additional arguments

Details
Prints a concise summary of konfound output with multiple types of data specified in the `to_return` argument
