Package ‘lubridate’

September 27, 2023

Type Package

Title Make Dealing with Dates a Little Easier

Version 1.9.3

Maintainer Vitalie Spinu <spinuvit@gmail.com>

Description Functions to work with date-times and time-spans: fast and user friendly parsing of date-time data, extraction and updating of components of a date-time (years, months, days, hours, minutes, and seconds), algebraic manipulation on date-time and time-span objects. The 'lubridate' package has a consistent and memorable syntax that makes working with dates easy and fun.

License GPL (>= 2)

BugReports https://github.com/tidyverse/lubridate/issues

Depends methods, R (>= 3.2)

Imports generics, timechange (>= 0.1.1)

Suggests covr, knitr, rmarkdown, testthat (>= 2.1.0), vctrs (>= 0.5.0)

Enhances chron, data.table, timeDate, tis, zoo

VignetteBuilder knitr

Config/Needs/website tidyverse/tidytemplate

Config/testthat/edition 3

Encoding UTF-8

LazyData true

RoxygenNote 7.2.3

SystemRequirements C++11, A system with zoneinfo data (e.g. /usr/share/zoneinfo). On Windows the zoneinfo included with R is used.

Index 76
**am**  
*Does date time occur in the am or pm?*

**Description**

Does date time occur in the am or pm?

**Usage**

```r
am(x)
```

```r
pm(x)
```

**Arguments**

- **x**  
a date-time object

**Value**

TRUE or FALSE depending on whether x occurs in the am or pm

**Examples**

```r
x <- ymd("2012-03-26")
am(x)
pm(x)
```

---

**as.duration**  
*Change an object to a duration*

**Description**

as.duration changes Interval, Period and numeric class objects to Duration objects. Numeric objects are changed to Duration objects with the seconds unit equal to the numeric value.

**Usage**

```r
as.duration(x, ...)
```

**Arguments**

- **x**  
Object to be coerced to a duration
- **...**  
Parameters passed to other methods. Currently unused.
Details

Durations are exact time measurements, whereas periods are relative time measurements. See Period. The length of a period depends on when it occurs. Hence, a one to one mapping does not exist between durations and periods. When used with a period object, as.duration provides an inexact estimate of the length of the period; each time unit is assigned its most common number of seconds. A period of one month is converted to 2628000 seconds (approximately 30.42 days). This ensures that 12 months will sum to 365 days, or one normal year. For an exact transformation, first transform the period to an interval with as.interval().

Value

A duration object

See Also

Duration, duration()

Examples

```r
span <- interval(ymd("2009-01-01"), ymd("2009-08-01")) # interval
as.duration(span)
as.duration(10) # numeric
dur <- duration(hours = 10, minutes = 6)
as.numeric(dur, "hours")
as.numeric(dur, "minutes")
```

as.interval

Change an object to an interval

Description

as.interval changes difftime, Duration, Period and numeric class objects to intervals that begin at the specified date-time. Numeric objects are first coerced to timespans equal to the numeric value in seconds.

Usage

```r
as.interval(x, start, ...)
```

Arguments

- **x**: a duration, difftime, period, or numeric object that describes the length of the interval
- **start**: a POSIXt or Date object that describes when the interval begins
- **...**: additional arguments to pass to as.interval
as.period

Description

as.period changes Interval, difftime, duration and numeric class objects to Period class objects with
the specified units.

Usage

as.period(x, unit, ...)

Details

as.interval can be used to create accurate transformations between Period objects, which measure
time spans in variable length units, and Duration objects, which measure timespans as an exact
number of seconds. A start date-time must be supplied to make the conversion. Lubridate uses
this start date to look up how many seconds each variable length unit (e.g. month, year) lasted for
during the time span described. See as.duration(), as.period().

Value

an interval object

See Also

interval()

Examples

diff <- make_difftime(days = 31) # difftime
as.interval(diff, ymd("2009-01-01"))
as.interval(diff, ymd("2009-02-01"))

dur <- duration(days = 31) # duration
as.interval(dur, ymd("2009-01-01"))
as.interval(dur, ymd("2009-02-01"))

per <- period(months = 1) # period
as.interval(per, ymd("2009-01-01"))
as.interval(per, ymd("2009-02-01"))

as.interval(3600, ymd("2009-01-01")) # numeric

as.period

Change an object to a period
as.period

Arguments

- **x**: an interval, difftime, or numeric object
- **unit**: A character string that specifies which time units to build period in. `unit` is only implemented for the `as.period.numeric` method and the `as.period.interval` method. For `as.period.interval`, `as.period` will convert intervals to units no larger than the specified unit.
- ... additional arguments to pass to `as.period`

Details

Users must specify which time units to measure the period in. The exact length of each time unit in a period will depend on when it occurs. See `Period` and `period()`. The choice of units is not trivial; units that are normally equal may differ in length depending on when the time period occurs. For example, when a leap second occurs one minute is longer than 60 seconds.

Because periods do not have a fixed length, they cannot be accurately converted to and from `Duration` objects. Duration objects measure time spans in exact numbers of seconds, see `Duration`. Hence, a one to one mapping does not exist between durations and periods. When used with a `Duration` object, `as.period` provides an inexact estimate; the duration is broken into time units based on the most common lengths of time units, in seconds. Because the length of months are particularly variable, a period with a months unit cannot be coerced from a duration object. For an exact transformation, first transform the duration to an interval with `as.interval()`.

Coercing an interval to a period may cause surprising behavior if you request periods with small units. A leap year is 366 days long, but one year long. Such an interval will convert to 366 days when unit is set to days and 1 year when unit is set to years. Adding 366 days to a date will often give a different result than adding one year. Daylight savings is the one exception where this does not apply. Interval lengths are calculated on the UTC timeline, which does not use daylight savings. Hence, periods converted with seconds or minutes will not reflect the actual variation in seconds and minutes that occurs due to daylight savings. These periods will show the "naive" change in seconds and minutes that is suggested by the differences in clock time. See the examples below.

Value

- a period object

See Also

- `Period`, `period()`

Examples

```r
span <- interval(ymd_hms("2009-01-01 00:00:00"), ymd_hms("2010-02-02 01:01:01")) # interval
as.period(span)
as.period(span, unit = "day")
"397d 1H 1M 1S"
leap <- interval(ymd("2016-01-01"), ymd("2017-01-01"))
as.period(leap, unit = "days")
as.period(leap, unit = "years")
dst <- interval(
```
as_date

Convert an object to a date or date-time

Description

Convert an object to a date or date-time

Usage

as_date(x, ...)

## S4 method for signature 'ANY'
as_date(x, ...)

## S4 method for signature 'POSIXt'
as_date(x, tz = NULL)

## S4 method for signature 'numeric'
as_date(x, origin = lubridate::origin)

## S4 method for signature 'character'
as_date(x, tz = NULL, format = NULL)

as_datetime(x, ...)

## S4 method for signature 'ANY'
as_datetime(x, tz = lubridate::tz(x))

## S4 method for signature 'POSIXt'
as_datetime(x, tz = lubridate::tz(x))

## S4 method for signature 'numeric'
as_datetime(x, origin = lubridate::origin, tz = "UTC")

## S4 method for signature 'character'
as_datetime(x, tz = "UTC", format = NULL)

## S4 method for signature 'Date'
as_datetime(x, tz = "UTC")
**Arguments**

- `x` a vector of POSIXlt, numeric or character objects
- `...` further arguments to be passed to specific methods (see above).
- `tz` a time zone name (default: time zone of the POSIXlt object `x`). See `OlsonNames()`.
- `origin` a Date object, or something which can be coerced by `as.Date(origin, ...)`. Note that in this instance, `x` is assumed to reflect the number of days since `origin` at "UTC".
- `format` format argument for character methods. When supplied parsing is performed by `parse_date_time(x, orders = formats, exact = TRUE)`. Thus, multiple formats are supported and are tried in turn.

**Value**

A vector of Date objects corresponding to `x`.

**Compare to base R**

These are drop in replacements for `as.Date()` and `as.POSIXct()`, with a few tweaks to make them work more intuitively.

- Called on a POSIXct object, `as_date()` uses the tzone attribute of the object to return the same date as indicated by the printed representation of the object. This differs from `as.Date`, which ignores the attribute and uses only the `tz` argument to `as.Date()` ("UTC" by default).
- Both functions provide a default origin argument for numeric vectors.
- Both functions will generate NAs for invalid date format. Valid formats are those described by ISO8601 standard. A warning message will provide a count of the elements that were not converted.
- `as_datetime()` defaults to using UTC.

**Examples**

```r
dt_utc <- ymd_hms("2010-08-03 00:50:50")
dt_europe <- ymd_hms("2010-08-03 00:50:50", tz = "Europe/London")
c(as_date(dt_utc), as.Date(dt_utc))
c(as_date(dt_europe), as.Date(dt_europe))
## need not supply origin
as_date(10)
## Will replace invalid date format with NA
dt_wrong <- c("2009-09-29", "2012-11-29", "2015-29-12")
as_date(dt_wrong)
```
cyclic_encoding

Cyclic encoding of date-times

Description

Encode a date-time object into a cyclic coordinate system in which the distances between two pairs of dates separated by the same time duration are the same.

Usage

```r
cyclic_encoding(
  x,
  periods,
  encoders = c("sin", "cos"),
  week_start = getOption("lubridate.week.start", 7)
)
```

Arguments

- `x` a date-time object
- `periods` a character vector of periods. Follows same specification as `period` and `floor_date` functions.
- `encoders` names of functions to produce the encoding. Defaults to "sin" and "cos". Names of any predefined functions accepting a numeric input are allowed.
- `week_start` week start day (Default is 7, Sunday. Set `lubridate.week.start` to override). Full or abbreviated names of the days of the week can be in English or as provided by the current locale.

Details

Machine learning models don’t know that December 31st and January 1st are close in our human calendar sense. `cyclic_encoding` makes it obvious to the machine learner that two calendar dates are close by mapping the dates onto the circle.

Value

a numeric matrix with number of columns equal `length(periods) * length(types)`.

Examples

```r
times <- ymd_hms("2019-01-01 00:00:00") + hours(0:23)
cyclic_encoding(times, c("day", "week", "month"))
plot(cyclic_encoding(times, "1d"))
plot(cyclic_encoding(times, "2d"), xlim = c(-1, 1))
plot(cyclic_encoding(times, "4d"), xlim = c(-1, 1))
```
date

Get/set date component of a date-time

Description

Date-time must be a POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and its objects.

Usage

date(x)
date(x) <- value

Arguments

x a date-time object
value an object for which the date() function is defined

Details

date() does not yet support years before 0 C.E. Also date() is not defined for Period objects.

Value

the date of x as a Date

Base compatibility

date() can be called without any arguments to return a string representing the current date-time. This provides compatibility with base:date() which it overrides.

Examples

x <- ymd_hms("2012-03-26 23:12:13", tz = "America/New_York")
date(x)
as.Date(x) # by default as.Date assumes you want to know the date in UTC
as.Date(x, tz = "America/New_York")
date(x) <- as.Date("2000-01-02")
x
DateTimeUpdate

Changes the components of a date object

Description

update.Date() and update.POSIXt() return a date with the specified elements updated. Elements
not specified will be left unaltered. update.Date and update.POSIXt do not add the specified values
to the existing date, they substitute them for the appropriate parts of the existing date.

Usage

## S3 method for class 'POSIXt'
update(
  object,
  ..., 
  roll_dst = c("NA", "post"),
  week_start = getOption("lubridate.week.start", 7),
  roll = NULL,
  simple = NULL
)

Arguments

object            a date-time object
...               named arguments: years, months, ydays, wdays, mdays, days, hours, minutes,
                  seconds, tzs (time zone component)
roll_dst          is a string vector of length one or two. When two values are supplied they spec-
                  ify how to roll date-times when they fall into "skipped" and "repeated" DST
                  transitions respectively. A single value is replicated to the length of two. Possi-
                  ble values are:
* `"pre"` - Use the time before the transition boundary.
* `"boundary"` - Use the time exactly at the boundary transition.
* `"post"` - Use the time after the boundary transition.
* `"xfirst"` - crossed-first: First time which occurred when crossing the
                  boundary. For addition with positive units pre interval is crossed first and
                  post interval last. With negative units post interval is crossed first, pre -
                  last. For subtraction the logic is reversed.
* `"xlast"` - crossed-last.
* `"NA"` - Produce NAs when the resulting time falls inside the problematic interval.

For example `roll_dst = c("NA", "pre")` indicates that for skipped intervals return
NA and for repeated times return the earlier time.

When multiple units are supplied the meaning of "negative period" is deter-
mined by the largest unit. For example `time_add(t, days = -1, hours = 2,
roll_dst = "xfirst")` would operate as if with negative period, thus crossing
the boundary from the "post" to "pre" side and "xfirst" and hence resolving to "post" time. As this might result in confusing behavior. See examples. "xfirst" and "xlast" make sense for addition and subtraction only. An error is raised if an attempt is made to use them with other functions.

**week_start**

week start day (Default is 7, Sunday. Set lubridate.week.start to override). Full or abbreviated names of the days of the week can be in English or as provided by the current locale.

**simple, roll**

deprecated

**Value**

a date object with the requested elements updated. The object will retain its original class unless an element is updated which the original class does not support. In this case, the date returned will be a POSIXlt date object.

**Examples**

date <- ymd("2009-02-10")
update(date, year = 2010, month = 1, mday = 1)
update(date, year = 2010, month = 13, mday = 1)
update(date, minute = 10, second = 3)

date_decimal

*Converts a decimal to a date*

**Description**

Converts a decimal to a date

**Usage**

date_decimal(decimal, tz = "UTC")

**Arguments**

decimal a numeric object
tz the time zone required

**Value**

a POSIXct object, whose year corresponds to the integer part of decimal. The months, days, hours, minutes and seconds elements are picked so the date-time will accurately represent the fraction of the year expressed by decimal.
Examples

```r
date <- ymd("2009-02-10")
decimal <- decimal_date(date) # 2009.11
date_decimal(decimal) # "2009-02-10 UTC"
```

day

Get/set days component of a date-time

Description

Get/set days component of a date-time

Usage

- `day(x)`
- `mday(x)`
- `wday(x, label = FALSE, abbr = TRUE, week_start =getOption("lubridate.week.start", 7), locale = Sys.getlocale("LC_TIME"))`
- `qday(x)`
- `yday(x)`
- `day(x) <- value`
- `mday(x) <- value`
- `qday(x) <- value`
- `qday(x) <- value`
- `wday(x, week_start = getOption("lubridate.week.start", 7)) <- value`
- `yday(x) <- value`

Arguments

- `x` - a POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, or fts object.
label logical. Only available for wday. TRUE will display the day of the week as an ordered factor of character strings, such as "Sunday." FALSE will display the day of the week as a number.

abbr logical. Only available for wday. FALSE will display the day of the week as an ordered factor of character strings, such as "Sunday." TRUE will display an abbreviated version of the label, such as "Sun". abbr is disregarded if label = FALSE.

week_start day on which week starts following ISO conventions: 1 means Monday and 7 means Sunday (default). When label = FALSE and week_start = 7, the number returned for Sunday is 1, for Monday is 2, etc. When label = TRUE, the returned value is a factor with the first level being the week start (e.g. Sunday if week_start = 7). You can set lubridate.week.start option to control this parameter globally.

locale locale to use for day names. Default to current locale.

value (for wday<-) a numeric or a string giving the name of the day in the current locale or in English. Can be abbreviated. When a string, the value of week_start is ignored.

Details

mday() and yday() return the day of the month and day of the year respectively. day() and day<-() are aliases for mday() and mday<-().

Value

wday() returns the day of the week as a decimal number or an ordered factor if label is TRUE.

Examples

x <- as.Date("2009-09-02")
wday(x) # 4
wday(x, label = TRUE) # Wed

wday(x, week_start = 1) # 3
wday(x, week_start = 7) # 4

wday(x, label = TRUE, week_start = 7) # Wed (Sun is the first level)
wday(x, label = TRUE, week_start = 1) # Wed (Mon is the first level)

wday(ymd(080101))
wday(ymd(080101), label = TRUE, abbr = FALSE)
wday(ymd(080101), label = TRUE, abbr = TRUE)
wday(ymd(080101) + days(-2:4), label = TRUE, abbr = TRUE)

x <- as.Date("2009-09-02")
yday(x) # 245
mday(x) # 2
yday(x) <- 1 # "2009-01-01"
yday(x) <- 366 # "2010-01-01"
mday(x) > 3
**days_in_month**

*Get the number of days in the month of a date-time*

**Description**

Date-time must be a POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and fts objects.

**Usage**

days_in_month(x)

**Arguments**

x

a date-time object

**Value**

An integer of the number of days in the month component of the date-time object.

---

**decimal_date**

*Converts a date to a decimal of its year*

**Description**

Converts a date to a decimal of its year

**Usage**

decimal_date(date)

**Arguments**

date

a POSIXt or Date object

**Value**

a numeric object where the date is expressed as a fraction of its year

**Examples**

date <- ymd("2009-02-10")
decimal_date(date) # 2009.11
**dst**

*Get daylight savings time indicator of a date-time*

**Description**

Date-time must be a POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and fts objects.

**Usage**

`dst(x)`

**Arguments**

- `x`: a date-time object

**Details**

A date-time's daylight savings flag can not be set because it depends on the date-time’s year, month, day, and hour values.

**Value**

A logical. TRUE if DST is in force, FALSE if not, NA if unknown.

**Examples**

```r
x <- ymd("2012-03-26")
dst(x)
```

---

**duration**

*Create a duration object.*

**Description**

duration() creates a duration object with the specified values. Entries for different units are cumulative. Durations display as the number of seconds in a time span. When this number is large, durations also display an estimate in larger units, however, the underlying object is always recorded as a fixed number of seconds. For display and creation purposes, units are converted to seconds using their most common lengths in seconds. Minutes = 60 seconds, hours = 3600 seconds, days = 86400 seconds, weeks = 604800. Units larger than weeks are not used due to their variability.
Usage

\texttt{duration(num = \textbf{NULL}, units = "seconds", ...)}

\texttt{dseconds(x = 1)}

\texttt{dminutes(x = 1)}

\texttt{dhours(x = 1)}

\texttt{ddays(x = 1)}

\texttt{dweeks(x = 1)}

\texttt{dmonths(x = 1)}

\texttt{dyears(x = 1)}

\texttt{dmilliseconds(x = 1)}

\texttt{dmicroseconds(x = 1)}

\texttt{dnanoseconds(x = 1)}

\texttt{dpicoseconds(x = 1)}

\texttt{is.duration(x)}

Arguments

\texttt{num} \hspace{1cm} \text{the number or a character vector of time units. In string representation all unambiguous name units and abbreviations and ISO 8601 formats are supported; ‘m’ stands for month and ‘M’ for minutes unless ISO 8601 “P” modifier is present (see examples). Fractional units are supported.}

\texttt{units} \hspace{1cm} \text{a character string that specifies the type of units that \texttt{num} refers to. When \texttt{num} is character, this argument is ignored.}

\texttt{...} \hspace{1cm} \text{a list of time units to be included in the duration and their amounts. Seconds, minutes, hours, days, weeks, months and years are supported. Durations of months and years assume that year consists of 365.25 days.}

\texttt{x} \hspace{1cm} \text{numeric value of the number of units to be contained in the duration.}

Details

Durations record the exact number of seconds in a time span. They measure the exact passage of time but do not always align with measurements made in larger units of time such as hours, months and years. This is because the length of larger time units can be affected by conventions such as leap years and Daylight Savings Time. Base R provides a second class for measuring durations, the \texttt{difftime} class.
Duration objects can be easily created with the helper functions `dweeks()`, `ddays()`, `dminutes()`, `dseconds()`. These objects can be added to and subtracted to date-times to create a user interface similar to object oriented programming.

**Value**

a duration object

**See Also**

`as.duration()` `Duration`

**Examples**

### Separate period and units vectors

```
duration(90, "seconds")
duration(1.5, "minutes")
duration(-1, "days")
```

### Units as arguments

```
duration(day = -1)
duration(second = 90)
duration(minute = 1.5)
duration(mins = 1.5)
duration(second = 3, minute = 1.5, hour = 2, day = 6, week = 1)
duration(hour = 1, minute = -60)
```

### Parsing

```
duration("2M 1sec")
duration("2hours 2minutes 1second")
duration("2d 2H 2M 2S")
duration("2days 2hours 2mins 2secs")
```

# Missing numerals default to 1. Repeated units are added up.

```
duration("day day")
```

### ISO 8601 parsing

```
duration("P3Y6M4DT12H30M5S")
duration("P23DT23H") # M stands for months
duration("10DT0M") # M stands for minutes
duration("P23DT60H 20min 100 sec") # mixing ISO and lubridate style parsing
```

# Comparison with characters (from v1.6.0)

```
duration("day 2 sec") > "day 1sec"
```

## ELEMENTARY CONSTRUCTORS:
Duration-class

Description

Duration is an S4 class that extends the Timespan class. Durations record the exact number of seconds in a time span. They measure the exact passage of time but do not always align with measurements made in larger units of time such as hours, months and years. This is because the exact length of larger time units can be affected by conventions such as leap years and Daylight Savings Time.

Details

Durations provide a method for measuring generalized timespans when we wish to treat time as a mathematical quantity that increases in a uniform, monotone manner along a continuous numberline. They allow exact comparisons with other durations. See Period for an alternative way to measure timespans that better preserves clock times.

Durations class objects have one slot: .Data, a numeric object equal to the number of seconds in the duration.
**fit_to_timeline**  
*Fit a POSIXlt date-time to the timeline*

**Description**

The POSIXlt format allows you to create instants that do not exist in real life due to daylight savings time and other conventions. `fit_to_timeline` matches POSIXlt date-times to a real times. If an instant does not exist, fit to timeline will replace it with an NA. If an instant does exist, but has been paired with an incorrect timezone/daylight savings time combination, `fit_to_timeline` returns the instant with the correct combination.

**Usage**

`fit_to_timeline(lt, class = "POSIXct", simple = FALSE)`

**Arguments**

- **lt**
  - a POSIXlt date-time object.
- **class**
  - a character string that describes what type of object to return, POSIXlt or POSIXct. Defaults to POSIXct. This is an optimization to avoid needless conversions.
- **simple**
  - if TRUE, lubridate makes no attempt to detect meaningless time-dates or to correct time zones. No NAs are produced and the most meaningful valid dates are returned instead. See examples.

**Value**

a POSIXct or POSIXlt object that contains no illusory date-times

**Examples**

```r
## Not run:
tricky <- structure(list(  
  sec = c(5, 0, 0, -1),  
  min = c(0L, 5L, 5L, 0L),  
  hour = c(2L, 0L, 2L, 2L),  
  mday = c(4L, 4L, 14L, 4L),  
  mon = c(10L, 10L, 2L, 10L),  
  year = c(112L, 112L, 110L, 112L),  
  wday = c(0L, 0L, 0L, 0L),  
  yday = c(308L, 308L, 72L, 308L),  
  isdst = c(1L, 0L, 0L, 1L)  
),  
.Names = c(  
  "sec", "min", "hour", "mday", "mon",  
  "year", "wday", "yday", "isdst"  
),  
.class = c("POSIXlt", "POSIXt"),
```

tzone = c("America/Chicago", "CST", "CDT")
)

tricky
## [1] "2012-11-04 02:00:00 CDT" Doesn't exist because clocks "fall back" to 1:00 CST
## [2] "2012-11-04 00:05:00 CST" Times are still CDT, not CST at this instant
## [3] "2010-03-14 02:00:00 CDT" DST gap
## [4] "2012-11-04 01:59:59 CDT" Does exist, but has deceptive internal structure

fit_to_timeline(tricky)
## Returns:
## [1] "2012-11-04 02:00:00 CST" instant paired with correct tz & DST combination
## [2] "2012-11-04 00:05:00 CDT" instant paired with correct tz & DST combination
## [3] NA - fake time changed to NA (compare to as.POSIXct(tricky))
## [4] "2012-11-04 01:59:59 CDT" -real instant, left as is

fit_to_timeline(tricky, simple = TRUE)
## Returns valid time-dates by extrapolating CDT and CST zones:
## [1] "2012-11-04 01:00:05 CST" "2012-11-04 01:05:00 CDT"
## [3] "2010-03-14 03:05:00 CDT" "2012-11-04 01:59:59 CDT"

## End(Not run)

---

force_tz

Replace time zone to create new date-time

Description

force_tz returns the date-time that has the same clock time as input time, but in the new time zone. force_tzs is the parallel version of force_tz, meaning that every element from time argument is matched with the corresponding time zone in tzones argument.

Usage

force_tz(time, tzone = "", ...)  

## Default S3 method:

force_tz(time, tzone = "", roll_dst = c("NA", "post"), roll = NULL, ...)

force_tzs(  
  time,  
  tzones,  
  tzone_out = "UTC",  
  roll_dst = c("NA", "post"),  
  roll = NULL  
)
force_tz

Arguments

time

a POSIXct, POSIXlt, Date, chron date-time object, or a data.frame object. When a data.frame all POSIXt elements of a data.frame are processed with force_tz() and new data.frame is returned.

tzone

a character string containing the time zone to convert to. R must recognize the name contained in the string as a time zone on your system.

...  

Parameters passed to other methods.

roll_dst

is a string vector of length one or two. When two values are supplied they specify how to roll date-times when they fall into "skipped" and "repeated" DST transitions respectively. A single value is replicated to the length of two. Possible values are:

* "pre" - Use the time before the transition boundary.
* "boundary" - Use the time exactly at the boundary transition.
* "post" - Use the time after the boundary transition.
* "xfirst" - crossed-first: First time which occurred when crossing the boundary. For addition with positive units pre interval is crossed first and post interval last. With negative units post interval is crossed first, pre last. For subtraction the logic is reversed.
* "xlast" - crossed-last.
* "NA" - Produce NAs when the resulting time falls inside the problematic interval.

For example ‘roll_dst = c("NA", "pre") indicates that for skipped intervals return NA and for repeated times return the earlier time.

When multiple units are supplied the meaning of "negative period" is determined by the largest unit. For example time_add(t, days = -1, hours = 2, roll_dst = "xfirst") would operate as if with negative period, thus crossing the boundary from the "post" to "pre" side and "xfirst" and hence resolving to "post" time. As this might result in confusing behavior. See examples.

"xfirst" and "xlast" make sense for addition and subtraction only. An error is raised if an attempt is made to use them with other functions.

roll

deprecated, same as roll_dst parameter.

tzones

character vector of timezones to be "enforced" on time time stamps. If time and tzones lengths differ, the smaller one is recycled in accordance with usual R conventions.

tzone_out

timezone of the returned date-time vector (for force_tzs).

Details

Although the new date-time has the same clock time (e.g. the same values in the year, month, days, etc. elements) it is a different moment of time than the input date-time.

As R date-time vectors cannot hold elements with non-uniform time zones, force_tzs returns a vector with time zone tzone_out, UTC by default.

Value

a POSIXct object in the updated time zone
format_ISO8601

Format in ISO8601 character format

Description
Format in ISO8601 character format

Usage
format_ISO8601(x, usetz = FALSE, precision = NULL, ...)

Examples
x <- ymd_hms("2009-08-07 00:00:01", tz = "America/New_York")
force_tz(x, "UTC")
force_tz(x, "Europe/Amsterdam")

## DST skip:
y <- ymd_hms("2010-03-14 02:05:05 UTC")
force_tz(y, "America/New_York", roll_dst = "NA")
force_tz(y, "America/New_York", roll_dst = "pre")
force_tz(y, "America/New_York", roll_dst = "boundary")
force_tz(y, "America/New_York", roll_dst = "post")

## DST repeat
y <- ymd_hms("2014-11-02 01:35:00", tz = "UTC")
force_tz(y, "America/New_York", roll_dst = "NA")
force_tz(y, "America/New_York", roll_dst = "pre")
force_tz(y, "America/New_York", roll_dst = "boundary")
force_tz(y, "America/New_York", roll_dst = "post")

## DST skipped and repeated
y <- ymd_hms("2010-03-14 02:05:05 UTC", "2014-11-02 01:35:00", tz = "UTC")
force_tz(y, "America/New_York", roll_dst = c("NA", "pre"))
force_tz(y, "America/New_York", roll_dst = c("boundary", "post"))

## Heterogeneous time-zones:
x <- ymd_hms(c("2009-08-07 00:00:01", "2009-08-07 01:02:03"))
force_tzs(x, tzones = c("America/New_York", "Europe/Amsterdam"))
force_tzs(x, tzones = c("America/New_York", "Europe/Amsterdam"), tzone_out = "America/New_York")

x <- ymd_hms("2009-08-07 00:00:01")
force_tzs(x, tzones = c("America/New_York", "Europe/Amsterdam"))

See Also
with_tz(), local_time()
Argument

- **x**: An object to convert to ISO8601 character format.
- **usetz**: Include the time zone in the formatting. If `usetz` is `TRUE`, the time zone is included. If `usetz` is "Z", the time is converted to "UTC" and the time zone is indicated with "Z" ISO8601 notation.
- **precision**: The amount of precision to represent with substrings of "ymdhms", as "y"ear, "m"onth, "d"ay, "h"our, "m"minute, and "s"ecound. (e.g. "ymdhms" would show precision through minutes. When NULL, full precision for the object is shown.
- ...: Additional arguments to methods.

Value

A character vector of ISO8601-formatted text.

References

Examples

```r
format_ISO8601(as.Date("02-01-2018", format = "%m-%d-%Y"))
format_ISO8601(as.POSIXct("2018-02-01 03:04:05", tz = "EST"), usetz = TRUE)
format_ISO8601(as.POSIXct("2018-02-01 03:04:05", tz = "EST"), precision = "ymdhm")
```

---

**guess_formats**

*Guess possible date-times formats from a character vector*

Description

Guess possible date-times formats from a character vector.

Usage

```r
guess_formats(
  x,
  orders,
  locale = Sys.getlocale("LC_TIME"),
  preproc_wday = TRUE,
  print_matches = FALSE
)
```
Arguments

- **x**: input vector of date-times.
- **orders**: format orders to look for. See examples.
- **locale**: locale to use. Defaults to the current locale.
- **preproc_wday**: whether to preprocess weekday names. Internal optimization used by `ymd_hms()` family of functions. If TRUE, weekdays are substituted with `%a` or `%A` accordingly, so that there is no need to supply this format explicitly.
- **print_matches**: for development purposes mainly. If TRUE, prints a matrix of matched templates.

Value

a vector of matched formats

Examples

```r
x <- c('February 20th 1973',
       'February 14, 2004',
       'Sunday, May 1, 2000',
       'Sunday, May 1, 2000',
       'February 14, 04',
       'Feb 20th 73',
       'February 20th 1973',
       'January 5 1999 at 7pm',
       'Jan 1 2010',
       'Jan 1, 1999',
       'Jan 3 10',
       '01 3 2010',
       '1 3 10',
       '1 13 89',
       '5/27/1979',
       '12/31/99',
       'DOB:12/11/00',
       '---------',
       'Thu, 1 July 2004 22:30:00',
       'Thu, 1st of July 2004 at 22:30:00',
       'Thu, 1July 2004 at 22:30:00',
       'Thu, 1July2004 22:30:00',
       'Thu, 1 July04 22:30:00',
       '21 Aug 2011, 11:15:34 pm',
       '---------',
       '1979-05-27 05:00:59',
       '1979-05-27',
       '---------',
       '3 jan 2000',
       '17 april 85',
       '27/5/1979',
       '20 01 89',
       '00/13/10',
       '---------',
       '14 12 00',
```
hour

"03:23:22 pm"

guess_formats(x, "BdY")
guess_formats(x, "Bdy")
## m also matches b and B; y also matches Y
guess_formats(x, "mdy", print_matches = TRUE)

## T also matches IMSp order
guess_formats(x, "T", print_matches = TRUE)

## b and B are equivalent and match, both, abbreviated and full names
guess_formats(x, c("mdY", "BdY", "Bdy", "bdY", "bdy"), print_matches = TRUE)
guess_formats(x, c("dmy", "dbY", "dBy", "dBY"), print_matches = TRUE)

guess_formats(x, c("dBY HMS", "dbY HMS", "dmyHMS", "BdY H"), print_matches = TRUE)
guess_formats(x, c("ymd HMS"), print_matches = TRUE)

---

**Description**

Date-time must be a POSIXct, POSIXlt, Date, Period, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and fts objects.

**Usage**

```r
hour(x)
hour(x) <- value
```

**Arguments**

- `x` : a date-time object
- `value` : numeric value to be assigned to the hour component

**Value**

the hours element of `x` as a decimal number

**Examples**

```r
x <- ymd("2012-03-26")
hour(x)
hour(x) <- 1
hour(x) <- 25
hour(x) > 2
```
interval

Utilities for creation and manipulation of Interval objects

Description

interval() creates an Interval object with the specified start and end dates. If the start date occurs before the end date, the interval will be positive. Otherwise, it will be negative. Character vectors in ISO 8601 format are supported from v1.7.2.

int_start()/int_end() and int_start<-()/int_end<-() are "accessors" and "setters" respectively of the start/end date of an interval.

int_flip() reverses the order of the start date and end date in an interval. The new interval takes place during the same timespan as the original interval, but has the opposite direction.

int_shift() shifts the start and end dates of an interval up or down the timeline by a specified amount. Note that this may change the exact length of the interval if the interval is shifted by a Period object. Intervals shifted by a Duration or difftime object will retain their exact length in seconds.

int_overlaps() tests if two intervals overlap.

int_standardize() ensures all intervals in an interval object are positive. If an interval is not positive, flip it so that it retains its endpoints but becomes positive.

int_aligns() tests if two intervals share an endpoint. The direction of each interval is ignored.

int_align tests whether the earliest or latest moments of each interval occur at the same time.

int_diff() returns the intervals that occur between the elements of a vector of date-times. int_diff() is similar to the POSIXt and Date methods of diff(), but returns an Interval object instead of a difftime object.

Usage

interval(start = NULL, end = NULL, tzone = tz(start))

start %--% end

is.interval(x)

int_start(int)

int_start(int) <- value

int_end(int)

int_end(int) <- value

int_length(int)

int_flip(int)
int_shift(int, by)
int_overlaps(int1, int2)
int_standardize(int)
int_aligns(int1, int2)
int_diff(times)

Arguments

- **start**, **end**: POSIXt, Date or a character vectors. When start is a character vector and end is NULL, ISO 8601 specification is assumed but with much more permissive lubridate style parsing both for dates and periods (see examples).
- **tzone**: a recognized timezone to display the interval in
- **x**: an R object
- **int**: an interval object
- **value**: interval’s start/end to be assigned to int
- **by**: A period or duration object to shift by (for int_shift)
- **int1**: an Interval object (for int_overlaps(), int_aligns())
- **int2**: an Interval object (for int_overlaps(), int_aligns())
- **times**: A vector of POSIXct, POSIXlt or Date class date-times (for int_diff())

Details

Intervals are time spans bound by two real date-times. Intervals can be accurately converted to either period or duration objects using `as.period()`, `as.duration()`. Since an interval is anchored to a fixed history of time, both the exact number of seconds that passed and the number of variable length time units that occurred during the interval can be calculated.

Value

- `interval()` – **Interval** object.
  - `int_start()` and `int_end()` return a POSIXct date object when used as an accessor. Nothing when used as a setter.
  - `int_length()` – numeric length of the interval in seconds. A negative number connotes a negative interval.
  - `int_flip()` – flipped interval object
  - `int_shift()` – an Interval object
  - `int_overlaps()` – logical, TRUE if int1 and int2 overlap by at least one second. FALSE otherwise
  - `int_aligns()` – logical, TRUE if int1 and int2 begin or end on the same moment. FALSE otherwise
  - `int_diff()` – interval object that contains the n-1 intervals between the n date-time in times
See Also

- `Interval`, `as.interval()`, `%within%`

Examples

```r
interval(ymd(20090201), ymd(20090101))

date1 <- ymd_hms("2009-03-08 01:59:59")
date2 <- ymd_hms("2000-02-29 12:00:00")
interval(date2, date1)
interval(date1, date2)
span <- interval(ymd(20090101), ymd(20090201))

### ISO Intervals

interval("2007-03-01T13:00:00Z/2008-05-11T15:30:00Z")
interval("2007-03-01T13:00:00Z/P1Y2M10DT2H30M")
interval("P1Y2M10DT2H30M/2008-05-11T15:30:00Z")
interval("2008-05-11/P2H30M")

### More permissive parsing (as long as there are no intermittent / characters)

interval("2008 05 11/P2hours 30minutes")
interval("08 05 11/P 2h 30m")

is.interval(period(months = 1, days = 15)) # FALSE

int_overlaps(int1, int3) # FALSE
int <- interval(ymd("2002-01-01"), ymd("2001-01-01"))
int_standardize(int)
int1 <- interval(ymd("2001-01-01"), ymd("2002-01-01"))
int2 <- interval(ymd("2001-06-01"), ymd("2002-01-01"))
```
```
int3 <- interval(ymd("2003-01-01"), ymd("2004-01-01"))

int_aligns(int1, int2)  # TRUE
int_aligns(int1, int3)  # FALSE

dates <- now() + days(1:10)
int_diff(dates)
```

### Description

Interval is an S4 class that extends the `Timespan` class. An Interval object records one or more spans of time. Intervals record these timespans as a sequence of seconds that begin at a specified date. Since intervals are anchored to a precise moment of time, they can accurately be converted to `Period` or `Duration` class objects. This is because we can observe the length in seconds of each period that begins on a specific date. Contrast this to a generalized period, which may not have a consistent length in seconds (e.g. the number of seconds in a year will change if it is a leap year).

### Details

Intervals can be both negative and positive. Negative intervals progress backwards from the start date; positive intervals progress forwards.

Interval class objects have two slots: `.Data`, a numeric object equal to the number of seconds in the interval; and `.start`, a POSIXct object that specifies the time when the interval starts.

---

### Description

The `Date()` function mirrors primitive constructors in base R (`double()`, `character()` etc.).

#### Usage

```r
is.Date(x)

Date(length = 0L)

NA_Date_
```

#### Arguments

- `x`: An R object
- `length`: A non-negative number specifying the desired length. Supplying an argument of length other than one is an error.
is.difftime

Format

An object of class Date of length 1.

See Also

is.instant(), is.timespan(), is.POSIXt(), POSIXct()

Examples

is.Date(as.Date("2009-08-03")) # TRUE
is.Date(difftime(now() + 5, now())) # FALSE

is.difftime

Is x a difftime object?

Description

Is x a difftime object?

Usage

is.difftime(x)

Arguments

x an R object

Value

TRUE if x is a difftime object, FALSE otherwise.

See Also

is.instant(), is.timespan(), is.interval(), is.period().

Examples

is.difftime(as.Date("2009-08-03")) # FALSE
is.difftime(make_difftime(days = 12.4)) # TRUE
is.instant  

Is x a date-time object?

Description

An instant is a specific moment in time. Most common date-time objects (e.g., POSIXct, POSIXlt, and Date objects) are instants.

Usage

is.instant(x)

is.timepoint(x)

Arguments

x an R object

Value

TRUE if x is a POSIXct, POSIXlt, or Date object, FALSE otherwise.

See Also

is.timespan(), is.POSIXt(), is.Date()

Examples

is.instant(as.Date("2009-08-03")) # TRUE
is.timepoint(5) # FALSE

is.POSIXt  

Various POSIX utilities

Description

POSIXct() mirrors primitive constructors in base R (double(), character() etc.)

Usage

is.POSIXt(x)

is.POSIXlt(x)

is.POSIXct(x)

POSIXct(length = 0L, tz = "UTC")

NA_POSIXct_
Arguments

x an R object

length A non-negative number specifying the desired length. Supplying an argument of length other than one is an error.

tz a timezone (defaults to "utc")

Format

An object of class POSIXct (inherits from POSIXt) of length 1.

Value

TRUE if x is a POSIXct or POSIXlt object, FALSE otherwise.

See Also

is.instant(), is.timespan(), is.Date()

Examples

is.POSIXt(as.Date("2009-08-03"))
is.POSIXt(as.POSIXct("2009-08-03"))
Examples

is.timespan(as.Date("2009-08-03")) # FALSE
is.timespan(duration(second = 1)) # TRUE

---

Lakers 2008-2009 basketball data set

Description

This data set contains play by play statistics of each Los Angeles Lakers basketball game in the 2008-2009 season. Data includes the date, opponent, and type of each game (home or away). Each play is described by the time on the game clock when the play was made, the period in which the play was attempted, the type of play, the player and team who made the play, the result of the play, and the location on the court where each play was made.

---

leap_year  
Is a year a leap year?

Description

If x is a recognized date-time object, leap_year will return whether x occurs during a leap year. If x is a number, leap_year returns whether it would be a leap year under the Gregorian calendar.

Usage

leap_year(date)

Arguments

date  
a date-time object or a year

Value

TRUE if x is a leap year, FALSE otherwise

Examples

x <- as.Date("2009-08-02")
leap_year(x) # FALSE
leap_year(2009) # FALSE
leap_year(2008) # TRUE
leap_year(1900) # FALSE
leap_year(2000) # TRUE
local_time

Get local time from a date-time vector.

Description
local_time retrieves day clock time in specified time zones. Computation is vectorized over both
dt and tz arguments, the shortest is recycled in accordance with standard R rules.

Usage
local_time(dt, tz = NULL, units = "secs")

Arguments
dt a date-time object.
tz a character vector of timezones for which to compute the local time.
units passed directly to `as.difftime()`.

Examples
x <- ymd_hms(c("2009-08-07 01:02:03", "2009-08-07 10:20:30"))
local_time(x, units = "secs")
local_time(x, units = "hours")
local_time(x, "Europe/Amsterdam")
local_time(x, "Europe/Amsterdam") == local_time(with_tz(x, "Europe/Amsterdam"))

x <- ymd_hms("2009-08-07 01:02:03")
local_time(x, c("America/New_York", "Europe/Amsterdam", "Asia/Shanghai"), unit = "hours")

make_datetime

Efficient creation of date-times from numeric representations

Description
make_datetime() is a very fast drop-in replacement for `base::ISOdate()` and `base::ISOdatetime()`.
make_date() produces objects of class Date.

Usage
make_datetime(
    year = 1970L,
    month = 1L,
    day = 1L,
    hour = 0L,
    min = 0L,
make_difftime

```
sec = 0,
tz = "UTC"
```

```
make_date(year = 1970L, month = 1L, day = 1L)
```

Arguments

- **year**: numeric year
- **month**: numeric month
- **day**: numeric day
- **hour**: numeric hour
- **min**: numeric minute
- **sec**: numeric second
- **tz**: time zone. Defaults to UTC.

Details

Input vectors are silently recycled. All inputs except sec are silently converted to integer vectors; sec can be either integer or double.

Examples

```
make_datetime(year = 1999, month = 12, day = 22, sec = 10)
make_datetime(year = 1999, month = 12, day = 22, sec = c(10, 11))
```

make_difftime

Create a difftime object.

Description

make_difftime() creates a difftime object with the specified number of units. Entries for different units are cumulative. difftime displays durations in various units, but these units are estimates given for convenience. The underlying object is always recorded as a fixed number of seconds.

Usage

```
make_difftime(num = NULL, units = "auto", ...)
```

Arguments

- **num**: Optional number of seconds
- **units**: a character vector that lists the type of units to use for the display of the return value (see examples). If units is "auto" (the default) the display units are computed automatically. This might create undesirable effects when converting difftime objects to numeric values in data processing.
... a list of time units to be included in the difftime and their amounts. Seconds, minutes, hours, days, and weeks are supported. Normally only one of num or ... are present. If both are present, the difftime objects are concatenated.

**Details**

Conceptually, difftime objects are a type of duration. They measure the exact passage of time but do not always align with measurements made in larger units of time such as hours, months and years. This is because the length of larger time units can be affected by conventions such as leap years and Daylight Savings Time. **lubridate** provides a second class for measuring durations, the Duration class.

**Value**

a difftime object

**See Also**

duration(), as.duration()

**Examples**

```r
make_difftime(1)
make_difftime(60)
make_difftime(3600)
make_difftime(3600, units = "minute")
# Time difference of 60 mins
make_difftime(second = 90)
# Time difference of 1.5 mins
make_difftime(minute = 1.5)
# Time difference of 1.5 mins
make_difftime(second = 3, minute = 1.5, hour = 2, day = 6, week = 1)
# Time difference of 13.08441 days
make_difftime(hour = 1, minute = -60)
# Time difference of 0 secs
make_difftime(day = -1)
# Time difference of -1 days
make_difftime(120, day = -1, units = "minute")
# Time differences in mins
```

---

**minute**

Get/set minutes component of a date-time

**Description**

Date-time must be a POSIXct, POSIXlt, Date, Period, chron, yearmon, yearqtr, zoo, zooreg, timeSeries, and its objects.
Usage

minute(x)

minute(x) <- value

Arguments

x a date-time object
value numeric value to be assigned

Value

the minutes element of x as a decimal number

Examples

x <- ymd("2012-03-26")
minute(x)
minute(x) <- 1
minute(x) <- 61
minute(x) > 2

month

Get/set months component of a date-time

Description

Date-time must be a POSIXct, POSIXlt, Date, Period, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and fts objects.

Usage

month(x, label = FALSE, abbr = TRUE, locale = Sys.getlocale("LC_TIME"))

month(x) <- value

Arguments

x a date-time object
label logical. TRUE will display the month as a character string such as "January." FALSE will display the month as a number.
abbr logical. FALSE will display the month as a character string label, such as "January". TRUE will display an abbreviated version of the label, such as "Jan". abbr is disregarded if label = FALSE.
locale for month, locale to use for month names. Default to current locale.
value a numeric object
Value

If `label = FALSE`: month as number (1-12, 1 = January, 12 = December), otherwise as an ordered factor.

Examples

```r
x <- ymd("2012-03-26")
month(x)
month(x) <- 1
month(x) <- 13
month(x) > 3

month(ymd(080101))
month(ymd(080101), label = TRUE)
month(ymd(080101), label = TRUE, abbr = FALSE)
month(ymd(080101) + months(0:11), label = TRUE)
```

Description

Transforms a character or numeric vector into a period object with the specified number of hours, minutes, and seconds. `hms()` recognizes all non-numeric characters except `:` as separators (`:` is used for negative durations). After hours, minutes and seconds have been parsed, the remaining input is ignored.

Usage

```r
ms(..., quiet = FALSE, roll = FALSE)
hm(..., quiet = FALSE, roll = FALSE)
hms(..., quiet = FALSE, roll = FALSE)
```

Arguments

- `...`: a character vector of hour minute second triples
- `quiet`: logical. If TRUE, function evaluates without displaying customary messages.
- `roll`: logical. If TRUE, smaller units are rolled over to higher units if they exceed the conventional limit. For example, `hms("01:59:120", roll = TRUE)` produces period "2H 1M 0S".

Value

- a vector of period objects
See Also

hm(), ms()

Examples

ms(c("09:10", "09:02", "1:10"))
ms("7 6")
ms("6.5")
hm(c("09:10", "09:02", "1:10"))
hm("7 6")
hm("6.5")

x <- c("09:10:01", "09:10:02", "09:10:03")
hms(x)
hms("7 6 5", "3:23:::2", "2 : 23 : 33", "Finished in 9 hours, 20 min and 4 seconds")

now

The current day and time

Description

The current day and time

Usage

now(tzone = "")
today(tzone = "")

Arguments

tzone a character vector specifying which time zone you would like the current time in. tzone defaults to your computer’s system timezone. You can retrieve the current time in the Universal Coordinated Time (UTC) with now("UTC").

Value

now - the current datetime as a POSIXct object

Examples

now()
now("GMT")
now("")
now() == now() # would be TRUE if computer processed both at the same instant
now() < now() # TRUE
now() > now() # FALSE
today()}
today("GMT")
today() == today("GMT") # not always true
today() < as.Date("2999-01-01") # TRUE (so far)

| origin | 1970-01-01 UTC |

Description

Origin is the date-time for 1970-01-01 UTC in POSIXct format. This date-time is the origin for the numbering system used by POSIXct, POSIXlt, chron, and Date classes.

Usage

origin

Format

An object of class POSIXct (inherits from POSIXt) of length 1.

Examples

origin

| parse_date_time | User friendly date-time parsing functions |

Description

parse_date_time() parses an input vector into POSIXct date-time object. It differs from base::strptime() in two respects. First, it allows specification of the order in which the formats occur without the need to include separators and the % prefix. Such a formatting argument is referred to as "order". Second, it allows the user to specify several format-orders to handle heterogeneous date-time character representations.

parse_date_time2() is a fast C parser of numeric orders.

fast_strptime() is a fast C parser of numeric formats only that accepts explicit format arguments, just like base::strptime().
Usage

```r
parse_date_time(
  x,
  orders,
  tz = "UTC",
  truncated = 0,
  quiet = FALSE,
  locale = Sys.getlocale("LC_TIME"),
  select_formats = .select_formats,
  exact = FALSE,
  train = TRUE,
  drop = FALSE
)
```

```r
parse_date_time2(
  x,
  orders,
  tz = "UTC",
  exact = FALSE,
  lt = FALSE,
  cutoff_2000 = 68L
)
```

```r
fast_strptime(x, format, tz = "UTC", lt = TRUE, cutoff_2000 = 68L)
```

Arguments

- **x**: a character or numeric vector of dates
- **orders**: a character vector of date-time formats. Each order string is a series of formatting characters as listed in `base::strptime()` but might not include the `%` prefix. For example, "ymd" will match all the possible dates in year, month, day order. Formatting orders might include arbitrary separators. These are discarded. See details for the implemented formats. If multiple order strings are supplied, they are applied in turn for `parse_date_time2()` and `fast_strptime()`. For `parse_date_time()` the order of applied formats is determined by `select_formats` parameter.
- **tz**: a character string that specifies the time zone with which to parse the dates
- **truncated**: integer, number of formats that can be missing. The most common type of irregularity in date-time data is the truncation due to rounding or unavailability of the time stamp. If the truncated parameter is non-zero `parse_date_time()` also checks for truncated formats. For example, if the format order is "ymdHMS" and `truncated = 3`, `parse_date_time()` will correctly parse incomplete date-times like `2012-06-01 12:23, 2012-06-01 12 and 2012-06-01`. **NOTE**: The `ymd()` family of functions is based on `base::strptime()` which currently fails to parse `%Y-%m` formats.
- **quiet**: logical. If TRUE, progress messages are not printed, and No formats found error is suppressed and the function simply returns a vector of NAs. This mirrors the
behavior of base R functions `base::strptime()` and `base::as.POSIXct()`.

`locale` locale to be used, see `locales`. On Linux systems you can use `system("locale -a")` to list all the installed locales.

`select_formats` A function to select actual formats for parsing from a set of formats which matched a training subset of x. It receives a named integer vector and returns a character vector of selected formats. Names of the input vector are formats (not orders) that matched the training set. Numeric values are the number of dates (in the training set) that matched the corresponding format. You should use this argument if the default selection method fails to select the formats in the right order. By default the formats with most formatting tokens (%) are selected and `%Y` counts as 2.5 tokens (so that it has a priority over `%y%m`). See examples.

`exact` logical. If TRUE, the orders parameter is interpreted as an exact `base::strptime()` format and no training or guessing are performed (i.e. train, drop parameters are ignored).

`train` logical, default TRUE. Whether to train formats on a subset of the input vector. As a result the supplied orders are sorted according to performance on this training set, which commonly results in increased performance. Please note that even when `train = FALSE` (and `exact = FALSE`) guessing of the actual formats is still performed on the training set (a pseudo-random subset of the original input vector). This might result in All formats failed to parse error. See notes below.

`drop` logical, default FALSE. Whether to drop formats that didn’t match on the training set. If FALSE, unmatched on the training set formats are tried as a last resort at the end of the parsing queue. Applies only when `train = TRUE`. Setting this parameter to TRUE might slightly speed up parsing in situations involving many formats. Prior to v1.7.0 this parameter was implicitly TRUE, which resulted in occasional surprising behavior when rare patterns were not present in the training set.

`lt` logical. If TRUE, returned object is of class POSIXlt, and POSIXct otherwise. For compatibility with `base::strptime()` the default is TRUE for `fast_strptime()` and FALSE for `parse_date_time2()`.

`cutoff_2000` integer. For `y` format, two-digit numbers smaller or equal to `cutoff_2000` are parsed as though starting with 20, otherwise parsed as though starting with 19. Available only for functions relying on lubridate internal parser.

`format` a vector of formats. If multiple formats supplied they are applied in turn till success. The formats should include all the separators and each format letter must be prefixed with %, just as in the format argument of `base::strptime()`.

**Details**

When several format-orders are specified, `parse_date_time()` selects (guesses) format-orders based on a training subset of the input strings. After guessing the formats are ordered according to the performance on the training set and applied recursively on the entire input vector. You can disable training with `train = FALSE`.

`parse_date_time()`, and all derived functions, such as `ymd_hms()`, `ymd()`, etc., will drop into `fast_strptime()` instead of `base::strptime()` whenever the guessed from the input data formats are all numeric.
The list below contains formats recognized by \texttt{lubridate}. For numeric formats leading 0s are optional. As compared to \texttt{base::strptime()}, some of the formats are new or have been extended for efficiency reasons. These formats are marked with "(*)" below. Fast parsers \texttt{parse_date_time2()} and \texttt{fast_strptime()} accept only formats marked with "(!)".

\begin{itemize}
\item[a] Abbreviated weekday name in the current locale. (Also matches full name)
\item[A] Full weekday name in the current locale. (Also matches abbreviated name).
\begin{itemize}
\item You don’t need to specify a and A formats explicitly. Wday is automatically handled if \texttt{preproc_wday = TRUE}
\end{itemize}
\item[b] Abbreviated or full month name in the current locale. The C parser currently understands only English month names.
\item[B] Same as b.
\item[d] Day of the month as decimal number (01–31 or 0–31)
\item[H] Hours as decimal number (00–24 or 0–24).
\item[I] Hours as decimal number (01–12 or 1–12).
\item[j] Day of year as decimal number (001–366 or 1–366).
\item[q] Quarter (1–4). The quarter month is added to the parsed month if \texttt{m} element is present.
\item[m] Month as decimal number (01–12 or 1–12). For \texttt{parse_date_time} also matches abbreviated and full months names as b and B formats. C parser understands only English month names.
\item[M] Minute as decimal number (00–59 or 0–59).
\item[p] AM/PM indicator in the locale. Commonly used in conjunction with I and not with H. But \texttt{lubridate}'s C parser accepts H format as long as hour is not greater than 12. C parser understands only English locale AM/PM indicator.
\item[S] Second as decimal number (00–61 or 0–61), allowing for up to two leap-seconds (but POSIX-compliant implementations will ignore leap seconds).
\item[OS] Fractional second.
\item[U] Week of the year as decimal number (00–53 or 0–53) using Sunday as the first day 1 of the week (and typically with the first Sunday of the year as day 1 of week 1). The US convention.
\item[w] Weekday as decimal number (0–6, Sunday is 0).
\item[W] Week of the year as decimal number (00–53 or 0–53) using Monday as the first day of week (and typically with the first Monday of the year as day 1 of week 1). The UK convention.
\item[y] Year without century (00–99 or 0–99). In \texttt{parse_date_time()} also matches year with century (Y format).
\item[Y] Year with century.
\item[z] ISO8601 signed offset in hours and minutes from UTC. For example \texttt{-0800, -08:00 or -08}, all represent 8 hours behind UTC. This format also matches the Z (Zulu) UTC indicator. Because \texttt{base::strptime()} doesn’t fully support ISO8601 this format is implemented as an union of 4 formats: Ou (Z), Oz (-0800), OO (-08:00) and Oo (-08). You can use these formats as any other but it is rarely necessary. \texttt{parse_date_time2()} and \texttt{fast_strptime()} support all of these formats.
\item[Om] Matches numeric month and English alphabetic months (Both, long and abbreviated forms).
\item[Op] Matches AM/PM English indicator.
\item[r] Matches Ip and H orders.
\item[R] Matches HM and HMp orders.
\item[T] Matches IMSp, HMS, and HMOS orders.
\end{itemize}
Value

a vector of POSIXct date-time objects

Note

parse_date_time() (and the derivatives ymd(), ymd_hms(), etc.) relies on a sparse guesser that takes at most 501 elements from the supplied character vector in order to identify appropriate formats from the supplied orders. If you get the error All formats failed to parse and you are confident that your vector contains valid dates, you should either set exact argument to TRUE or use functions that don't perform format guessing (fast_strptime(), parse_date_time2() or base::strptime()).

For performance reasons, when timezone is not UTC, parse_date_time2() and fast_strptime() perform no validity checks for daylight savings time. Thus, if your input string contains an invalid date time which falls into DST gap and lt = TRUE you will get an POSIXlt object with a nonexistent time. If lt = FALSE your time instant will be adjusted to a valid time by adding an hour. See examples. If you want to get NA for invalid date-times use fit_to_timeline() explicitly.

base::strptime(), ymd(), ymd_hms()

Examples

```r
## ** orders are much easier to write **
x <- c("09-01-01", "09-01-02", "09-01-03")
parse_date_time(x, "ymd")
parse_date_time(x, "y m d")
parse_date_time(x, "%y%m%d")
# "2009-01-01 UTC" "2009-01-02 UTC" "2009-01-03 UTC"

## ** heterogeneous date-times **
x <- c("09-01-01", "090102", "09-01 03", "09-01-03 12:02")
parse_date_time(x, c("ymd", "ymd HM"))

## ** different ymd orders **
x <- c("2009-01-01", "02022010", "02-02-2010")
parse_date_time(x, c("dmY", "ymd"))
# "2009-01-01 UTC" "2010-02-02 UTC" "2010-02-02 UTC"

## ** truncated time-dates **
parse_date_time(x, "Ymd HMS", truncated = 3)

## ** specifying exact formats and avoiding training and guessing **
parse_date_time(x, c("%m-%d-%Y", "%m%d%Y", "%m-%d-%Y %H:%M"), exact = TRUE)
parse_date_time(c("12/17/1996 04:00:00", "4/18/1950 0130"),
              c("%m/%d/%Y %I:%M:%S", "%m/%d/%Y %H%M"), exact = TRUE)

## ** quarters and partial dates **
parse_date_time(c("2016.2", "2016-04"), orders = "Yq")
```
### Create or parse period objects

**Description**

`period()` creates or parses a period object with the specified values.

**Usage**

```r
period(num = NULL, units = "second", ...)

is.period(x)
```
seconds(x = 1)
minutes(x = 1)
hours(x = 1)
days(x = 1)
weeks(x = 1)
years(x = 1)
milliseconds(x = 1)
microseconds(x = 1)
nanoseconds(x = 1)
picoseconds(x = 1)

## S3 method for class 'numeric'
months(x, abbreviate)

### Arguments

- **num**: a numeric or character vector. A character vector can specify periods in a convenient shorthand format or ISO 8601 specification. All unambiguous name units and abbreviations are supported, "m" stands for months, "M" for minutes unless ISO 8601 "P" modifier is present (see examples). Fractional units are supported but the fractional part is always converted to seconds.

- **units**: a character vector that lists the type of units to be used. The units in units are matched to the values in num according to their order. When num is character, this argument is ignored.

- **...**: a list of time units to be included in the period and their amounts. Seconds, minutes, hours, days, weeks, months, and years are supported. Normally only one of num or ... are present. If both are present, the periods are concatenated.

- **x**: Any R object for is.periods and a numeric value of the number of units for elementary constructors. With the exception of seconds(), x must be an integer.

- **abbreviate**: Ignored. For consistency with S3 generic in base namespace.

### Details

Within a Period object, time units do not have a fixed length (except for seconds) until they are added to a date-time. The length of each time unit will depend on the date-time to which it is added. For example, a year that begins on 2009-01-01 will be 365 days long. A year that begins on 2012-01-01 will be 366 days long. When math is performed with a period object, each unit is applied...
separately. How the length of a period is distributed among its units is non-trivial. For example, when leap seconds occur 1 minute is longer than 60 seconds.

Periods track the change in the "clock time" between two date-times. They are measured in common time related units: years, months, days, hours, minutes, and seconds. Each unit except for seconds must be expressed in integer values.

Besides the main constructor and parser `period()`, period objects can also be created with the specialized functions `years()`, `months()`, `weeks()`, `days()`, `hours()`, `minutes()`, and `seconds()`. These objects can be added to and subtracted to date-times to create a user interface similar to object oriented programming.

Note: Arithmetic with periods can result in undefined behavior when non-existent dates are involved (such as February 29th in non-leap years). Please see `Period` for more details and `%m+%` and `add_with_rollback()` for alternative operations.

Value

A period object

See Also

`Period`, `period()`, `%m+%`, `add_with_rollback()`

Examples

```r
### Separate period and units vectors
period(c(90, 5), c("second", "minute"))  # "5M 90S"
period(-1, "days")
period(c(3, 1, 2, 13, 1), c("second", "minute", "hour", "day", "week"))
period(c(1, -60), c("hour", "minute"))
period(0, "second")

### Units as arguments
period(second = 90, minute = 5)
period(day = -1)
period(second = 3, minute = 1, hour = 2, day = 13, week = 1)
period(hour = 1, minute = -60)
period(second = 0)
period(c(1, -60), c("hour", "minute"), hour = c(1, 2), minute = c(3, 4))

### Lubridate style parsing
period("2M 1sec")
period("2hours 2minutes 1second")
period("2d 2H 2M 2S")
period("2days 2hours 2mins 2secs")
period("2 days, 2 hours, 2 mins, 2 secs")
# Missing numerals default to 1. Repeated units are added up.
```
period("day day")

### ISO 8601 parsing

period("P18M23DT23H") # M stands for months
period("T100T10M") # M stands for minutes
period("P3Y6M4DT12H30M5S") # M for both minutes and months
period("P23DT60H 20min 100 sec") # mixing ISO and lubridate style parsing

### Comparison with characters (from v1.6.0)

period("day 2 sec") > "day 1sec"

### Elementary Constructors

x <- ymd("2009-08-03")
x + days(1) + hours(6) + minutes(30)
x + days(100) - hours(8)

class(as.Date("2009-08-09") + days(1)) # retains Date class
as.Date("2009-08-09") + hours(12)
class(as.Date("2009-08-09") + hours(12))
# converts to POSIXt class to accommodate time units

years(1) - months(7)
c(1:3) * hours(1)
hours(1:3)

# sequencing
y <- ymd(090101) # "2009-01-01 CST"
y + months(0:11)

# compare DST handling to durations
boundary <- ymd_hms("2009-03-08 01:59:59", tz = "America/Chicago")
boundary + days(1) # period
boundary + ddays(1) # duration
is.period(as.Date("2009-08-03")) # FALSE
is.period(period(months = 1, days = 15)) # TRUE

---

**period_to_seconds**

**Contrive a period to/from a given number of seconds**

**Description**

period_to_seconds() approximately converts a period to seconds assuming there are 365.25 days in a calendar year and 365.25/12 days in a month.

seconds_to_period() create a period that has the maximum number of non-zero elements (days, hours, minutes, seconds). This computation is exact because it doesn’t involve years or months.
pretty_dates

Usage

period_to_seconds(x)
seconds_to_period(x)

Arguments

x A numeric object. The number of seconds to coerce into a period.

Value

A number (period) that roughly equates to the period (seconds) given.

pretty_dates Computes attractive axis breaks for date-time data

Description

pretty_dates identifies which unit of time the sub-intervals should be measured in to provide approximately \( n \) breaks. It then chooses a "pretty" length for the sub-intervals and sets start and endpoints that 1) span the entire range of the data, and 2) allow the breaks to occur on important date-times (i.e. on the hour, on the first of the month, etc.)

Usage

pretty_dates(x, n, ...)

Arguments

x a vector of POSIXct, POSIXlt, Date, or chron date-time objects
n integer value of the desired number of breaks
... additional arguments to pass to function

Value

a vector of date-times that can be used as axis tick marks or bin breaks

Examples

x <- seq.Date(as.Date("2009-08-02"), by = "year", length.out = 2)
pretty_dates(x, 12)
quarter

Get the fiscal quarter and semester of a date-time

Description

Quarters divide the year into fourths. Semesters divide the year into halves.

Usage

```r
quarter(
  x,
  type = "quarter",
  fiscal_start = 1,
  with_year = identical(type, "year.quarter")
)
```

```r
semester(x, with_year = FALSE)
```

Arguments

- **x**: a date-time object of class POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, fts or anything else that can be converted with as.POSIXlt.
- **type**: the format to be returned for the quarter. Can be one one of "quarter" - return numeric quarter (default), "year.quarter" return the ending year and quarter as a number of the form year.quarter, "date_first" or "date_last" - return the date at the quarter’s start or end, "year_start/end" - return a full description of the quarter as a string which includes the start and end of the year (ex. “2020/21 Q1”).
- **fiscal_start**: numeric indicating the starting month of a fiscal year.
- **with_year**: logical indicating whether or not to include the quarter or semester's year (deprecated; use the type parameter instead).

Value

numeric or a vector of class POSIXct if type argument is date_first or date_last. When type is year.quarter the year returned is the end year of the financial year.

Examples

```r
x <- ymd(c("2012-03-26", "2012-05-04", "2012-09-23", "2012-12-31"))
quarter(x)
quarter(x, type = "year.quarter")
quarter(x, type = "year.quarter", fiscal_start = 11)
quarter(x, type = "date_first", fiscal_start = 11)
quarter(x, type = "date_last", fiscal_start = 11)
semester(x)
semester(x, with_year = TRUE)
```
rollbackard

Roll back or forward a date the previous, current or next month

Description

rollbackard() changes a date to the last day of the previous month or to the first day of the month. rollforward() rolls to the last day of the current month or to the first day of the next month. Optionally, the new date can retain the same hour, minute, and second information. rollback() is a synonym for rollbackard().

Usage

rollbackard(dates, roll_to_first = FALSE, preserve_hms = TRUE)
rollback(dates, roll_to_first = FALSE, preserve_hms = TRUE)
rollforward(dates, roll_to_first = FALSE, preserve_hms = TRUE)

Arguments

dates A POSIXct, POSIXlt or Date class object.
roll_to_first Rollback to the first day of the month instead of the last day of the month
preserve_hms Retains the same hour, minute, and second information? If FALSE, the new date will be at 00:00:00.

Value

A date-time object of class POSIXlt, POSIXct or Date, whose day has been adjusted to the last day of the previous month, or to the first day of the month.

Examples

date <- ymd("2010-03-03")
rollbackard(date)

dates <- date + months(0:2)
rollbackard(dates)

date <- ymd_hms("2010-03-03 12:44:22")
rollbackard(date)
rollbackard(date, roll_to_first = TRUE)
rollbackard(date, preserve_hms = FALSE)
rollbackard(date, roll_to_first = TRUE, preserve_hms = FALSE)
round_date() takes a date-time object and time unit, and rounds it to the nearest value of the specified time unit. For rounding date-times which are exactly halfway between two consecutive units, the convention is to round up. Note that this is in line with the behavior of R’s `base::round.POSIXt()` function but does not follow the convention of the base `base::round()` function which "rounds to the even digit", as per IEC 60559.

Rounding to the nearest unit or multiple of a unit is supported. All meaningful specifications in the English language are supported - secs, min, mins, 2 minutes, 3 years etc.

Rounding to fractional seconds is also supported. Please note that rounding to fractions smaller than 1 second can lead to large precision errors due to the floating point representation of the POSIXct objects. See examples.

floor_date() takes a date-time object and rounds it down to the nearest boundary of the specified time unit.

ceiling_date() takes a date-time object and rounds it up to the nearest boundary of the specified time unit.

Usage

```r
code
round_date(
  x,
  unit = "second",
  week_start = getOption("lubridate.week.start", 7)
)

code
floor_date(
  x,
  unit = "seconds",
  week_start = getOption("lubridate.week.start", 7)
)

code
ceiling_date(
  x,
  unit = "seconds",
  week_start = getOption("lubridate.week.start", 7)
)
```

Arguments

- `x` a vector of date-time objects
`round_date`  

- **unit**: a string, `Period` object or a date-time object. When a singleton string, it specifies a time unit or a multiple of a unit to be rounded to. Valid base units are `second`, `minute`, `hour`, `day`, `week`, `month`, `bimonth`, `quarter`, `season`, `halfyear` and `year`. Arbitrary unique English abbreviations as in the `period()` constructor are allowed. Rounding to multiples of units (except weeks) is supported. When `unit` is a `Period` object, it is first converted to a string representation which might not be in the same units as the constructor. For example, `weeks(1)` is converted to "7d 0H 0M 0S". Thus, always check the string representation of the period before passing to this function. When `unit` is a date-time object rounding is done to the nearest of the elements in `unit`. If range of `unit` vector does not cover the range of `x` `ceiling_date()` and `floor_date()` round to the `max(x)` and `min(x)` for elements that fall outside of `range(unit)`.

- **week_start**: week start day (Default is 7, Sunday. Set `lubridate.week.start` to override). Full or abbreviated names of the days of the week can be in English or as provided by the current locale.

- **change_on_boundary**: if this is `NULL` (the default), instants on the boundary remain unchanged, but `Date` objects are rounded up to the next boundary. If this is `TRUE`, instants on the boundary are rounded up to the next boundary. If this is `FALSE`, nothing on the boundary is rounded up at all. This was the default for `lubridate` prior to v1.6.0. See section Rounding Up Date Objects below for more details.

**Details**

In `lubridate`, functions that round date-time objects try to preserve the class of the input object whenever possible. This is done by first rounding to an instant, and then converting to the original class as per usual R conventions.

**Value**

When `unit` is a string, return a `Date` object if `x` is a `Date` and `unit` is larger or equal than "day", otherwise a `POSIXct` object. When `unit` is a date-time object, return a date-time object of the same class and same time zone as `unit`.

**Rounding Up Date Objects**

By default, rounding up `Date` objects follows 3 steps:

1. Convert to an instant representing lower bound of the `Date`: `2000-01-01` -> `2000-01-01 00:00:00`

2. Round up to the next closest rounding unit boundary. For example, if the rounding unit is `month` then next closest boundary of `2000-01-01` is `2000-02-01 00:00:00`. The motivation for this is that the "partial" `2000-01-01` is conceptually an interval (`2000-01-01 00:00:00` – `2000-01-02 00:00:00`) and the day hasn’t started clocking yet at the exact boundary `00:00:00`. Thus, it seems wrong to round a day to its lower boundary. Behavior on the boundary can be changed by setting `change_on_boundary` to `TRUE` or `FALSE`.

3. If the rounding unit is smaller than a day, return the instant from step 2 (`POSIXct`), otherwise convert to and return a `Date` object.

`base::round()`

Examples

```r
## print fractional seconds
options(digitssecs = 6)

x <- ymd_hms("2009-08-03 12:01:59.23")
round_date(x, ".5s")
round_date(x, "sec")
round_date(x, "second")
round_date(x, "minute")
round_date(x, "5 mins")
round_date(x, "hour")
round_date(x, "2 hours")
round_date(x, "day")
round_date(x, "week")
round_date(x, "month")
round_date(x, "bimonth")
round_date(x, "quarter") == round_date(x, "3 months")
round_date(x, "halfyear")
round_date(x, "year")

x <- ymd_hms("2009-08-03 12:01:59.23")
floor_date(x, ".1s")
floor_date(x, "second")
floor_date(x, "minute")
floor_date(x, "hour")
floor_date(x, "day")
floor_date(x, "week")
floor_date(x, "month")
floor_date(x, "bimonth")
floor_date(x, "quarter")
floor_date(x, "season")
floor_date(x, "halfyear")
floor_date(x, "year")

x <- ymd_hms("2009-08-03 12:01:59.23")
ceiling_date(x, ".1 sec") # imprecise representation at 0.1 sec !!!
ceiling_date(x, "second")
ceiling_date(x, "minute")
ceiling_date(x, "5 mins")
ceiling_date(x, "hour")
ceiling_date(x, "day")
ceiling_date(x, "week")
ceiling_date(x, "month")
ceiling_date(x, "bimonth") == ceiling_date(x, "2 months")
ceiling_date(x, "quarter")
ceiling_date(x, "season")
ceiling_date(x, "halfyear")
```
second

```r
ceiling_date(x, "year")

## Period unit argument
floor_date(x, days(2))
floor_date(x, years(1))

## As of R 3.4.2 POSIXct printing of fractional numbers is wrong
as.POSIXct("2009-08-03 12:01:59.3") ## -> "2009-08-03 12:01:59.2 CEST"
ceiling_date(x, ".1 sec") ## -> "2009-08-03 12:01:59.2 CEST"

## behaviour of `change_on_boundary`
## As per default behaviour 'NULL', instants on the boundary remain the
## same but dates are rounded up
ceiling_date(ymd_hms("2000-01-01 00:00:00"), "month")
ceiling_date(ymd("2000-01-01"), "month")

## If 'TRUE', both instants and dates on the boundary are rounded up
ceiling_date(ymd_hms("2000-01-01 00:00:00"), "month", change_on_boundary = TRUE)
ceiling_date(ymd("2000-01-01"), "month")

## If 'FALSE', both instants and dates on the boundary remain the same
ceiling_date(ymd_hms("2000-01-01 00:00:00"), "month", change_on_boundary = FALSE)
ceiling_date(ymd("2000-01-01"), "month")

x <- ymd_hms("2000-01-01 00:00:00")
ceiling_date(x, "month")
ceiling_date(x, "month", change_on_boundary = TRUE)

## For Date objects first day of the month is not on the
## "boundary". change_on_boundary applies to instants only.
x <- ymd("2000-01-01")
ceiling_date(x, "month")
ceiling_date(x, "month", change_on_boundary = TRUE)
```

---

### second

Get/set seconds component of a date-time

#### Description

Date-time must be a POSIXct, POSIXlt, Date, Period, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and its objects.

#### Usage

```r
second(x)
second(x) <- value
```
Arguments

- **x**: a date-time object
- **value**: numeric value to be assigned

Value

- the seconds element of x as a decimal number

Examples

```r
x <- ymd("2012-03-26")
second(x)
second(x) <- 1
second(x) <- 61
second(x) > 2
```

---

**stamp**  
*Format dates and times based on human-friendly templates*

Description

Stamps are just like `format()`, but based on human-friendly templates like "Recorded at 10 am, September 2002" or "Meeting, Sunday May 1, 2000, at 10:20 pm".

Usage

```r
stamp(
  x,
  orders = lubridate_formats,
  locale = Sys.getlocale("LC_TIME"),
  quiet = FALSE,
  exact = FALSE
)
```

```r
stamp_date(x, locale = Sys.getlocale("LC_TIME"), quiet = FALSE)
```

```r
stamp_time(x, locale = Sys.getlocale("LC_TIME"), quiet = FALSE)
```

Arguments

- **x**: a character vector of templates.
- **orders**: orders are sequences of formatting characters which might be used for disambiguation. For example "ymd hms", "aym" etc. See `guess_formats()` for a list of available formats.
- **locale**: locale in which x is encoded. On Linux-like systems use `locale -a` in the terminal to list available locales.
quiet  whether to output informative messages.
exact  logical. If TRUE, the orders parameter is interpreted as an exact base::strptime()
format and no format guessing is performed.

Details

stamp() is a stamping function date-time templates mainly, though it correctly handles all date
and time formats as long as they are unambiguous. stamp_date(), and stamp_time() are the
specialized stamps for dates and times (MHS). These function might be useful when the input
template is unambiguous and matches both a time and a date format.

Lubridate tries hard to guess the formats, but often a given format can be interpreted in multiple
ways. One way to deal with such cases is to provide unambiguous formats like 22/05/81 instead of
10/05/81 for d/m/y format. Another way is to use a more specialized stamp_date and stamp_time.
The core function stamp() prioritizes longer date-time formats.

If x is a vector of values lubridate will choose the format which "fits" x the best. Note that longer
formats are preferred. If you have "22:23:00 PM" then "HMSp" format will be given priority to
shorter "HMS" order which also fits the supplied string.

Finally, you can give desired format order directly as orders argument.

Value

a function to be applied on a vector of dates

See Also
guess_formats(), parse_date_time(), strftime()

Examples

D <- ymd("2010-04-05") - days(1:5)
stamp("March 1, 1999")(D)
sf <- stamp("Created on Sunday, Jan 1, 1999 3:34 pm")
sf(D)
stamp("Jan 01")(D)
就没有 stamp("Sunday, May 1, 2000", locale = "C")(D)
stamp("Sun Aug 5")(D) # => "Sun Aug 04" "Sat Aug 04" "Fri Aug 04" "Thu Aug 04" "Wed Aug 03"
stamp("12/31/99")(D) # => "06/09/11"
stamp("Sunday, May 1, 2000 22:10", locale = "C")(D)
stamp("2013-01-01T06:00:00Z")(D)
stamp("2013-01-01T00:00:00-06")(D)
stamp("2013-01-01T00:00:08:00")(force_tz(D, "America/Chicago"))
Description

A time span can be measured in three ways: as a duration, an interval, or a period.

- **durations** record the exact number of seconds in a time span. They measure the exact passage of time but do not always align with human measurements like hours, months and years.
- **periods** record the change in the clock time between two date-times. They are measured in human units: years, months, days, hours, minutes, and seconds.
- **intervals** are time spans bound by two real date-times. Intervals can be accurately converted to periods and durations.

Examples

duration(3690L, "seconds")
period(3690L, "seconds")
period(second = 30L, minute = 1L, hour = 1L)
interval(ymd_hms("2009-08-09 13:01:30"), ymd_hms("2009-08-09 12:00:00"))

date <- ymd_hms("2009-03-08 01:59:59") # DST boundary
date + days(1)
date + ddays(1)

date2 <- ymd_hms("2000-02-29 12:00:00")
date2 + years(1)
# self corrects to next real day

date3 <- ymd_hms("2009-01-31 01:00:00")
date3 + c(0:11) * months(1)

span <- date2 %--% date # creates interval

date <- ymd_hms("2009-01-01 00:00:00")
date + years(1)
date - days(3) + hours(6)
date + 3 * seconds(10)

months(6L) + days(1)

Description

Compute the exact length of a time span

**time_length**
Usage

time_length(x, unit = "second")

## S4 method for signature 'Interval'
time_length(x, unit = "second")

Arguments

x a duration, period, difftime or interval
unit a character string that specifies with time units to use

Details

When x is an Interval object and unit are years or months, time_length() takes into account the fact that all months and years don’t have the same number of days.

When x is a Duration, Period or difftime() object, length in months or years is based on their most common lengths in seconds (see timespan()).

Value

the length of the interval in the specified unit. A negative number connotes a negative interval or duration

See Also

timespan()

Examples

int <- interval(ymd("1980-01-01"), ymd("2014-09-18"))
time_length(int, "week")

# Exact age
time_length(int, "year")

# Age at last anniversary
trunc(time_length(int, "year"))

# Example of difference between intervals and durations
int <- interval(ymd("1900-01-01"), ymd("1999-12-31"))
time_length(int, "year")
time_length(as.duration(int), "year")
Description

Conveniently get and set the time zone of a date-time.  
tz<- is an alias for force_tz(), which preserves the local time, creating a different instant in time.  
Use with_tz() if you want keep the instant the same, but change the printed representation.

Usage

    tz(x)
    tz(x) <- value

Arguments

    x         A date-time vector, usually of class POSIXct or POSIXlt.
    value     New value of time zone.

Value

    A character vector of length 1. An empty string (""") represents your current time zone.
    For backward compatibility, the time zone of a date, NA, or character vector is "UTC".

Valid time zones

    Time zones are stored in system specific database, so are not guaranteed to be the same on every system (however, they are usually pretty similar unless your system is very out of date). You can see a complete list with OlsonNames().

See Also

    See DateTimeClasses for a description of the underlying tzone attribute..

Examples

    x <- y <- ymd_hms("2012-03-26 10:10:00", tz = "UTC")
    tz(x)

# Note that setting tz() preserved the clock time, which implies
# that the actual instant in time is changing
    tz(y) <- "Pacific/Auckland"
    y
    x - y

# This is the same as force_tz()
    force_tz(x, "Pacific/Auckland")
# Use with_tz() if you want to change the time zone, leave
# the instant in time the same
with_tz(x, "Pacific/Auckland")

---

**week**

*Get/set weeks component of a date-time*

### Description

- `week()` returns the number of complete seven day periods that have occurred between the date and January 1st, plus one.
- `isoweek()` returns the week as it would appear in the ISO 8601 system, which uses a reoccurring leap week.
- `epiweek()` is the US CDC version of epidemiological week. It follows same rules as `isoweek()` but starts on Sunday. In other parts of the world the convention is to start epidemiological weeks on Monday, which is the same as `isoweek`.

### Usage

- `week(x)`
- `week(x) <- value`
- `isoweek(x)`
- `epiweek(x)`

### Arguments

- **x**: a date-time object. Must be a `POSIXct`, `POSIXlt`, `Date`, `chron`, `yearmon`, `yearqtr`, `zoo`, `zooreg`, `timeDate`, `xts`, `its`, `ti`, `jul`, `timeSeries`, or `fts` object.
- **value**: a numeric object

### Value

- the weeks element of x as an integer number

### References

### See Also

- `isoyear()`
Examples

```r
x <- ymd("2012-03-26")
week(x)
week(x) <- 1
week(x) <- 54
week(x) > 3
```

---

**with_tz**

*Get date-time in a different time zone*

**Description**

`with_tz` returns a date-time as it would appear in a different time zone. The actual moment of time measured does not change, just the time zone it is measured in. `with_tz` defaults to the Universal Coordinated time zone (UTC) when an unrecognized time zone is inputted. See `Sys.timezone()` for more information on how R recognizes time zones.

**Usage**

```r
with_tz(time, tzone = "", ...)  
## Default S3 method:  
with_tz(time, tzone = "", ...)  
```

**Arguments**

- `time`: a POSIXct, POSIXlt, Date, chron date-time object or a data.frame object. When a data.frame all POSIXt elements of a data.frame are processed with `with_tz()` and new data.frame is returned.
- `tzone`: a character string containing the time zone to convert to. R must recognize the name contained in the string as a time zone on your system.
- `...`: Parameters passed to other methods.

**Value**

a POSIXct object in the updated time zone

**See Also**

`force_tz()`

**Examples**

```r
x <- ymd_hms("2009-08-07 00:00:01", tz = "America/New_York")
with_tz(x, "GMT")
```
**year**  
*Get/set years component of a date-time*

**Description**
Date-time must be a POSIXct, POSIXlt, Date, Period or any other object convertible to POSIXlt.

- `isoyear()` returns years according to the ISO 8601 week calendar.
- `epiyear()` returns years according to the epidemiological week calendars.

**Usage**
```
year(x)
year(x) <- value
isoyear(x)
epiyear(x)
```

**Arguments**
- `x`  
a date-time object
- `value`  
a numeric object

**Details**
year does not yet support years before 0 C.E.

**Value**
the years element of x as a decimal number

**References**
https://en.wikipedia.org/wiki/ISO_week_date

**Examples**
```
x <- ymd("2012-03-26")
year(x)
year(x) <- 2001
year(x) > 1995
```
ymd

Parse dates with year, month, and day components

Description

Transminds dates stored in character and numeric vectors to Date or POSIXct objects (see tz argument). These functions recognize arbitrary non-digit separators as well as no separator. As long as the order of formats is correct, these functions will parse dates correctly even when the input vectors contain differently formatted dates. See examples.

Usage

ymd(
  ..., 
  quiet = FALSE,
  tz = NULL,
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

ydm(
  ..., 
  quiet = FALSE,
  tz = NULL,
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

mdy(
  ..., 
  quiet = FALSE,
  tz = NULL,
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

myd(
  ..., 
  quiet = FALSE,
  tz = NULL,
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

dmy(
  ..., 
  quiet = FALSE,
Arguments

... a character or numeric vector of suspected dates
quiet logical. If TRUE, function evaluates without displaying customary messages.
tz Time zone indicator. If NULL (default), a Date object is returned. Otherwise a POSIXct with time zone attribute set to tz.
locale locale to be used, see locales. On Linux systems you can use system("locale -a") to list all the installed locales.
truncated integer. Number of formats that can be truncated.

Details

In case of heterogeneous date formats, the ymd() family guesses formats based on a subset of the input vector. If the input vector contains many missing values or non-date strings, the subset might not contain meaningful dates and the date-time format won’t be guessed resulting in All formats failed to parse error. In such cases please see parse_date_time() for a more flexible parsing interface.

If the truncated parameter is non-zero, the ymd() functions also check for truncated formats. For example, ymd() with truncated = 2 will also parse incomplete dates like 2012-06 and 2012.

NOTE: The ymd() family of functions is based on parse_date_time() and thus directly drop to the internal C parser for numeric months, but uses base::strptime() for alphabetic months. This implies that some of base::strptime()'s limitations are inherited by lubridate's parser. For example, truncated formats (like %Y-%b) will not be parsed. Numeric truncated formats (like %Y-%m) are handled correctly by lubridate's C parser.

As of version 1.3.0, lubridate's parse functions no longer return a message that displays which format they used to parse their input. You can change this by setting the lubridate.verbose option to TRUE with options(lubridate.verbose = TRUE).
Value

a vector of class POSIXct if tz argument is non-NULL or Date if tz is NULL (default)

See Also

parse_date_time() for an even more flexible low level mechanism.

Examples

```r
x <- c("09-01-01", "09-01-02", "09-01-03")
ymd(x)

x <- c("2009-01-01", "2009-01-02", "2009-01-03")
ymd(x)

ymd(090101, 90102)
now() > ymd(20090101)
## TRUE
dmy(010210)
mdy(010210)

yq('2014.2')

## heterogeneous formats in a single vector:

x <- c(20090101, "2009-01-02", "2009 01 03", "2009-1-4", 
"2009-1, 5", "Created on 2009 1 6", "200901 !!! 07")

ymd(x)

## What lubridate might not handle:

## Extremely weird cases when one of the separators is "" and some of the 
## formats are not in double digits might not be parsed correctly:

## Not run: ymd("201002-01", "201002-1", "20102-1")
dmy("0312-2010", "312-2010")
## End(Not run)
```

---

**ymd_hms**

Parse date-times with year, month, and day, hour, minute, and second components.

Description

Transform dates stored as character or numeric vectors to POSIXct objects. The ymd_hms() family of functions recognizes all non-alphanumeric separators (with the exception of "." if frac = TRUE) and correctly handles heterogeneous date-time representations. For more flexibility in treatment of heterogeneous formats, see low level parser `parse_date_time()`.
ymd_hms

Usage

ymd_hms(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0 
)

ymd_hm(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0 
)

ymd_h(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0 
)

dmy_hms(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0 
)

dmy_hm(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0 
)

dmy_h(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0 
)
mdy_hms(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0
)

mdy_hm(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0
)

mdy_h(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0
)

ydm_hms(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0
)

ydm_hm(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0
)

ydm_h(
  ..., 
  quiet = FALSE, 
  tz = "UTC", 
  locale = Sys.getlocale("LC_TIME"), 
  truncated = 0
)
Arguments

- a character vector of dates in year, month, day, hour, minute, second format
- quiet logical. If TRUE, function evaluates without displaying customary messages.
- tz a character string that specifies which time zone to parse the date with. The string must be a time zone that is recognized by the user’s OS.
- locale locale to be used, see locales. On Linux systems you can use system("locale -a") to list all the installed locales.
- truncated integer, indicating how many formats can be missing. See details.

Details

The ymd_hms() functions automatically assign the Universal Coordinated Time Zone (UTC) to the parsed date. This time zone can be changed with force_tz().

The most common type of irregularity in date-time data is the truncation due to rounding or unavailability of the time stamp. If the truncated parameter is non-zero, the ymd_hms() functions also check for truncated formats. For example, ymd_hms() with truncated = 3 will also parse incomplete dates like 2012-06-01 12:23, 2012-06-01 12 and 2012-06-01.

In case of heterogeneous date formats the ymd_hms() family guesses formats based on a subset of the input vector. If the input vector contains many missing values or non-date strings, the subset might not contain meaningful dates and the date-time format won’t be guessed resulting in All formats failed to parse error. In such cases please see parse_date_time() for a more flexible parsing interface.

As of version 1.3.0, lubridate’s parse functions no longer return a message that displays which format they used to parse their input. You can change this by setting the lubridate.verbose option to TRUE with options(lubridate.verbose = TRUE).

Value

a vector of POSIXct date-time objects

See Also

- ymd(), hms()
- parse_date_time() for the underlying mechanism

Examples

```r
x <- c("2010-04-14-04-35-59", "2010-04-01-12-00-00")
ymd_hms(x)
```

```r
x <- c("2011-12-31 12:59:59", "2010-01-01 12:00:00")
ymd_hms(x)
```

```r
## ** heterogeneous formats **
x <- c(20100101120101, "2009-01-02 12-01-02", "2009.01.03 12:01:03",
```

```r
```
```r
```
Add and subtract months to a date without exceeding the last day of the new month

Description

Adding months frustrates basic arithmetic because consecutive months have different lengths. With other elements, it is helpful for arithmetic to perform automatic roll over. For example, 12:00:00 + 61 seconds becomes 12:01:01. However, people often prefer that this behavior NOT occur with months. For example, we sometimes want January 31 + 1 month = February 28 and not March 3. \%m+% performs this type of arithmetic. Date \%m+% months(n) always returns a date in the nth month
after Date. If the new date would usually spill over into the n+1th month, `%m+%` will return the last day of the nth month (`rollback()`). Date `%m-%` months(n) always returns a date in the nth month before Date.

**Usage**

```
e1 %m+% e2
```

```
add_with_rollback(e1, e2, roll_to_first = FALSE, preserve_hms = TRUE)
```

**Arguments**

- **e1**: A period or a date-time object of class POSIXlt, POSIXct or Date.
- **e2**: A period or a date-time object of class POSIXlt, POSIXct or Date. Note that one of e1 and e2 must be a period and the other a date-time object.
- **roll_to_first**: Rollback to the first day of the month instead of the last day of the previous month (passed to `rollback()`)
- **preserve_hms**: Retains the same hour, minute, and second information? If FALSE, the new date will be at 00:00:00 (passed to `rollback()`)

**Details**

- `%m+%` and `%m-%` handle periods with components less than a month by first adding/subtracting months and then performing usual arithmetics with smaller units.
- `%m+%` and `%m-%` should be used with caution as they are not one-to-one operations and results for either will be sensitive to the order of operations.

**Value**

A date-time object of class POSIXlt, POSIXct or Date

**Examples**

```
jan <- ymd_hms("2010-01-31 03:04:05")
jan + months(1:3) # Feb 31 and April 31 returned as NA
# NA "2010-03-31 03:04:05 UTC" NA
jan %m+% months(1:3) # No rollover

leap <- ymd("2012-02-29")
"2012-02-29 UTC"
leap %m+% years(1)
leap %m+% years(-1)
leap %m-% years(1)

x <- ymd_hms("2019-01-29 01:02:03")
add_with_rollback(x, months(1))
add_with_rollback(x, months(1), preserve_hms = FALSE)
add_with_rollback(x, months(1), roll_to_first = TRUE)
add_with_rollback(x, months(1), roll_to_first = TRUE, preserve_hms = FALSE)
```
**%within%**

Does a date (or interval) fall within an interval?

### Description

Check whether a lies within the interval b, inclusive of the endpoints.

### Usage

```
a %within% b
```

### Arguments

- **a**: An interval or date-time object.
- **b**: Either an interval vector, or a list of intervals.
  
  If b is an interval (or interval vector) it is recycled to the same length as a. If b is a list of intervals, a is checked if it falls within any of the intervals, i.e. a %within% list(int1, int2) is equivalent to a %within% int1 | a %within% int2.

### Value

A logical vector.

### Examples

```
int <- interval(ymd("2001-01-01"), ymd("2002-01-01"))
int2 <- interval(ymd("2001-06-01"), ymd("2002-01-01"))

ymd("2001-05-03") %within% int # TRUE
int2 %within% int # TRUE
ymd("1999-01-01") %within% int # FALSE

## recycling (carefully note the difference between using a vector of ## intervals and list of intervals for the second argument)
dates <- ymd(c("2014-12-20", "2014-12-30", "2015-01-01", "2015-01-03"))
blackout_vector <- c(
  interval(ymd("2014-12-30"), ymd("2014-12-31")),
  interval(ymd("2014-12-30"), ymd("2015-01-03"))
)
dates %within% blackout_vector

## within ANY of the intervals of a list
dates <- ymd(c("2014-12-20", "2014-12-30", "2015-01-01", "2015-01-03"))
lst <- list(
  interval(ymd("2014-12-30"), ymd("2014-12-31")),
  interval(ymd("2014-12-30"), ymd("2015-01-03"))
)
dates %within% lst
```
## interval within a list of intervals

```r
int <- interval(
  ymd("2014-12-20", "2014-12-30"),
  ymd("2015-01-01", "2015-01-03")
)
int %within% lst
```
