Package ‘matsindf’

August 24, 2020

Type Package
Title Matrices in Data Frames
Version 0.3.6
Date 2020-08-24
Maintainer Matthew Heun <matthew.heun@me.com>
Description Provides functions to collapse a tidy data frame into matrices in a data frame and expand a data frame of matrices into a tidy data frame.

add_UKEnergy2000_matnames

Add a column of matrix names to tidy data frame

Description

Add a column of matrix names to tidy data frame

Usage

add_UKEnergy2000_matnames(
  .DF,
  ledger_side_colname = "Ledger.side",
  energy_colname = "E.ktoe",
  supply_side = "Supply",
  consumption_side = "Consumption",
  matname_colname = "matname",
  U_name = "U",
  V_name = "V",
  Y_name = "Y"
)

Arguments

.DF a data frame with ledger_side_colname and energy_colname.
ledger_side_colname the name of the column in .DF that contains ledger side (a string). Default is "Ledger.side".
energy_colname the name of the column in .DF that contains energy values (a string). Default is "E.ktoe".
supply_side the identifier for items on the supply side of the ledger (a string). Default is "Supply".
consumption_side the identifier for items on the consumption side of the ledger (a string). Default is "Consumption".
add_UKEnergy2000_row_col_meta

matname_colname
the name of the output column containing the name of the matrix in which this row belongs (a string). Default is "UVY".

U_name
the name for the use matrix (a string). Default is "U".

V_name
the name for the make matrix (a string). Default is "V".

Y_name
the name for the final demand matrix (a string). Default is "Y".

Value

.DF with an added column, UVY_colname.

Examples

matsindf:::add_UKEnergy2000_matnames(UKEnergy2000)

Description

Add row, column, row type, and column type metadata

Usage

add_UKEnergy2000_row_col_meta(
  .DF,
  matname_colname = "matname",
  U_name = "U",
  V_name = "V",
  Y_name = "Y",
  product_colname = "Product",
  flow_colname = "Flow",
  industry_type = "Industry",
  product_type = "Product",
  sector_type = "Sector",
  rowname_colname = "rowname",
  colname_colname = "colname",
  rowtype_colname = "rowtype",
  coltype_colname = "coltype"
)
**Arguments**

- `.DF`: a data frame containing `matname_colname`.
- `matname_colname`: the name of the column in `.DF` that contains names of matrices (a string). Default is "matname".
- `U_name`: the name for use matrices (a string). Default is "U".
- `V_name`: the name for make matrices (a string). Default is "V".
- `Y_name`: the name for final demand matrices (a string). Default is "Y".
- `product_colname`: the name of the column in `.DF` where Product names is found (a string). Default is "Product".
- `flow_colname`: the name of the column in `.DF` where Flow information is found (a string). The Flow column usually contains the industries involved in this flow. Default is "Flow".
- `industry_type`: the name that identifies production industries and and transformation processes (a string). Default is "Industry".
- `product_type`: the name that identifies energy carriers (a string). Default is "Product".
- `sector_type`: the name that identifies final demand sectors (a string). Default is "Sector".
- `rowname_colname`: the name of the output column that contains row names for matrices (a string). Default is "rowname".
- `colname_colname`: the name of the output column that contains column names for matrices (a string). Default is "colname".
- `rowtype_colname`: the name of the output column that contains row types for matrices (a string). Default is "rowtype".
- `coltype_colname`: the name of the output column that contains column types for matrices (a string). Default is "coltype".

**Value**

`.DF` with additional columns named `rowname_colname`, `colname_colname`, `rowtype_colname`, and `coltype_colname`.

**Examples**

```r
UKEnergy2000 %>%
matsindf:::add_UKEnergy2000_matnames(.) %>%
matsindf:::add_UKEnergy2000_row_col_meta(.)
```
collapse_to_matrices  

**Description**

A "tidy" data frame contains information that can be collapsed into matrices, including columns for matrix names, row names, column names, row types, column types, and values (entries in matrices). These column names are specified as strings by the `matnames`, `rownames`, `colnames`, `rowtypes`, `coltypes`, and `values` arguments to `collapse_to_matrices`, respectively. A `matsindf`-style matrix has named rows and columns. In addition, `matsindf`-style matrices have "types" for row and column information, such as "Commodities", "Industries", "Products", or "Machines". The row and column types for the `matsindf`-style matrices are stored as attributes on the matrix (rowtype and coltype), which can be accessed with the `rowtype` and `coltype` functions of the `matsbyname` package.

Row and column types are both respected and propagated by the various `_byname` functions of the `matsbyname` package. Use the `_byname` functions when you do operations on the `matsindf`-style matrices. The `matsindf`-style matrices will be stored in a column with same name as the incoming values column. This function is similar to `nest`, which stores data frames into a cell of a data frame. With `collapse_to_matrices`, matrices are created. This function is similar to `summarise` in that groups are respected. (In fact, calls to this function may not work properly unless grouping is provided. Errors of the form "Error: Duplicate identifiers for rows ..." are usually fixed by grouping `.DF` prior to calling this function.) The usual approach is to `group_by` the `matnames` column and any other columns to be preserved in the output. Note that execution is halted if any of `rownames`, `rowtypes`, `colnames`, `coltypes`, or `values` is a grouping variable. `rowtypes` and `coltypes` should be the same for all rows of the same matrix; execution is halted if that is not the case. Spreading the output by `matnames` may be necessary before calculations are done on the matrices. See the example.

**Usage**

```r
collapse_to_matrices(
  .DF,
  matnames = "matnames",
  matvals = "matvals",
  rownames = "rownames",
  colnames = "colnames",
  rowtypes = "rowtypes",
  coltypes = "coltypes"
)
```

**Arguments**

- `.DF`  
  the "tidy" data frame

- `matnames`  
  a string identifying the column in `.DF` containing matrix names for matrices to be created. Default is "matnames".

- `matvals`  
  a string identifying the column in `.DF` containing values to be inserted into the matrices to be created. This will also be the name of the column in the output
collapse_to_matrices

containing matrices formed from the data in the matvals column. Default is "matvals".

rownames  a string identifying the column in .DF containing row names for matrices to be created. Default is "rownames".

colnames  a string identifying the column in .DF containing column names for matrices to be created. Default is "colnames".

rowtypes  optional string identifying the column in .DF containing the type of values in rows of the matrices to be created. Default is "rowtypes".

coltypes  optional string identifying the column in .DF containing the type of values in columns of the matrices to be created Default is "coltypes".

Details

Groups are not preserved on output.

Value

a data frame with matrices in columns

See Also

nest and summarise.

Examples

library(dplyr)
library(tidyr)
library(tibble)
ptype <- "Products"
itype <- "Industries"
"U", "U", "E", "E", "eta", "eta"),
row = c("c 1", "c 2", "c 2", "c 2", "i 1", "i 2",
"c 1", "c 1", "c 1", "c 2", NA, NA),
col = c("i 1", "i 2", "i 1", "i 2", "i 2", "i 3", "c 1", "c 2",
"i 1", "i 2", "i 1", "i 2", NA, NA),
rowtypes = c(pptype, pptype, pptype, pptype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, NA, NA),
coltypes = c(itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, itype, NA, NA),
vals = c(11, 22, 11, 22, 23, 11, 22,
11, 12, 11, 22, 0.2, 0.3)
) %>% group_by(Country, Year, matrix)
mats <- collapse_to_matrices(tidy, matnames = "matrix", matvals = "vals",
rownames = "row", colnames = "col",
rowtypes = "rowtypes", coltypes = "coltypes")
mats %>% spread(key = matrix, value = vals)
everything_except

Get symbols for all columns except ...

Description

This convenience function performs a set difference between the columns of .DF and the variable names (or symbols) given in ... The return value is a list of symbols.

Usage

everything_except(.DF, ..., .symbols = TRUE)

Arguments

- **.DF**: a data frame whose variable names are to be differenced
- **...**: a string, strings, vector of strings, or list of strings representing column names to be subtracted from the names of .DF
- **.symbols**: a boolean that defines the return type: TRUE for symbols, FALSE for strings

Value

- a vector of symbols (when symbols = TRUE) or strings (when symbol = FALSE) containing all variables names except those given in ...

Examples

```r
DF <- data.frame(a = c(1, 2), b = c(3, 4), c = c(5, 6))
everything_except(DF, "a", "b")
everything_except(DF, "a", "b", symbols = FALSE)
everything_except(DF, c("a", "b"))
everything_except(DF, list("a", "b"))
```

expand_to_tidy

Expand a "tidy" data frame with matsindf-style matrices to a "tidy" data frame with each matrix entry as an observation

Description

A data frame with matsindf-style matrices contains matrices with names matnames in the column specified by matvals). An IO-style matrix has named rows and columns. In addition, matsindf-style matrices have "types" for row and column information, such as "Commodities", "Industries", "Products", or "Machines".
Usage

```
expand_to_tidy(
  .DF,
  matnames = "matnames",
  matvals = "matvals",
  rownames = "rownames",
  colnames = "colnames",
  rowtypes = "rowtypes",
  coltypes = "coltypes",
  drop = NA
)
```

Arguments

- **.DF**: the data frame containing `matsindf`-style matrices. (.DF may also be a named list of matrices, in which case names of the matrices are taken from the names of items in the list and list items are expected to be matrices.)
- **matnames**: name of the column in .DF containing matrix names (a string). Default is "matnames".
- **matvals**: name of the column in .DF containing IO-style matrices or constants (a string). This will also be the name of the column containing matrix entries in the output data frame. Default is "matvals".
- **rownames**: name for the output column of row names (a string). Default is "rownames".
- **colnames**: name for the output column of column names (a string). Default is "colnames".
- **rowtypes**: optional name for the output column of row types (a string). Default is "rowtypes".
- **coltypes**: optional name for the output column of column types (a string) Default is "coltypes".
- **drop**: if specified, the value to be dropped from output. For example, drop = 0 will cause 0 entries in the matrices to be deleted from output. If NA, no values are dropped from output. Default is NA.

Details

Names for output columns are specified in the rownames, colnames, rowtypes, and coltypes, arguments. The entries of the `matsindf`-style matrices are stored in an output column named values.

Value

a tidy data frame containing expanded `matsindf`-style matrices

Examples

```
library(dplyr)
library(matsbyname)
ptype <- "Products"
itype <- "Industries"
```

group_by_everything_except

\[ \text{group_by_everything_except} \]

\( \text{Group by all variables except some} \)

Description

This is a convenience function that allows grouping of a data frame by all variables (columns) except those variables specified in \( \ldots \).

Usage

\[ \text{group_by_everything_except(.DF, \ldots, .add = FALSE, .drop = FALSE)} \]

Arguments

- \( .\text{DF} \)  
  a data frame to be grouped

- \( \ldots \)  
  a string, strings, vector of strings, or list of strings representing column names to be excluded from grouping

- \( .\text{add} \)  
  When \( .\text{add} = \text{FALSE} \), the default, \texttt{dplyr::group_by()} will override existing groups. To add to the existing groups, use \( .\text{add} = \text{TRUE} \).

- \( .\text{drop} \)  
  When \( .\text{drop} = \text{TRUE} \), empty groups are dropped.
Value

a grouped version of .DF

Examples

library(dplyr)
DF <- data.frame(a = c(1, 2), b = c(3, 4), c = c(5, 6))
group_by_everything_except(DF) %>% group_vars()
group_by_everything_except(DF, NULL) %>% group_vars()
group_by_everything_except(DF, c()) %>% group_vars()
group_by_everything_except(DF, list()) %>% group_vars()
group_by_everything_except(DF, c) %>% group_vars()
group_by_everything_except(DF, "a") %>% group_vars()
group_by_everything_except(DF, "c") %>% group_vars()
group_by_everything_except(DF, c("a", "c")) %>% group_vars()
group_by_everything_except(DF, c("a")) %>% group_vars()
group_by_everything_except(DF, list("a")) %>% group_vars()

---

index_column

Index a column in a data frame by groups relative to an initial year

Description

This function indexes (by ratio) variables in var_to_index to the first time in time_var or to index_time (if specified). Groups in .DF are both respected and required. Neither var_to_index nor time_var can be in the grouping variables.

Usage

index_column(
  .DF,            # the data frame in which the variables are contained
  var_to_index,  # the column name representing the variable to be indexed (a string)
  time_var = "Year",  # the name of the column containing time information. Default is "Year".
  index_time = NULL,  # the time to which data in var_to_index are indexed. If NULL (the default), index_time is set to the first time of each group.
  indexed_var = paste0(var_to_index, suffix),  # the name of the indexed variable. Default is "<<var_to_index>>_<<suffix>>".
  suffix = "_indexed"  # the suffix to be appended to the indexed variable. Default is "_indexed"
)

Arguments

.DF        # the data frame in which the variables are contained
var_to_index        # the column name representing the variable to be indexed (a string)
time_var            # the name of the column containing time information. Default is "Year".
index_time          # the time to which data in var_to_index are indexed. If NULL (the default), index_time is set to the first time of each group.
indexed_var         # the name of the indexed variable. Default is "<<var_to_index>>_<<suffix>>".
suffix              # the suffix to be appended to the indexed variable. Default is "_indexed".
Details

Note that this function works when the variable to index is a column of numbers or a column of matrices.

Value

a data frame with same number of rows as .DF and the following columns: grouping variables of .DF, var_to_index, time_var, and one additional column containing indexed var_to_index named with the value of indexed_var.

Examples

library(dplyr)
library(tidyr)
DF <- data.frame(Year = c(2000, 2005, 2010), a = c(10, 15, 20), b = c(5, 5.5, 6)) %>%
  gather(key = name, value = var, a, b) %>%
  group_by(name)
index_column(DF, var_to_index = "var", time_var = "Year", suffix = "_ratioed")
index_column(DF, var_to_index = "var", time_var = "Year", indexed_var = "now.indexed")
index_column(DF, var_to_index = "var", time_var = "Year", index_time = 2005,
  indexed_var = "now.indexed")
## Not run:
DF %>%
  ungroup() %>%
  group_by(name, var) %>%
  index_column(var_to_index = "var", time_var = "Year") # Fails! Do not group on var_to_index.
DF %>%
  ungroup() %>%
  group_by(name, Year) %>%
  index_column(var_to_index = "var", time_var = "Year") # Fails! Do not group on time_var.
## End(Not run)

matsindf_apply  
Apply a function to a matsindf data frame (and more)

Description

Applies FUN to .dat or performs the calculation specified by FUN on numbers or matrices. FUN must return a named list.

Usage

matsindf_apply(.dat = NULL, FUN, ...)

Arguments

.dat  
a list of named items or a data frame.
FUN  
the function to be applied to .dat.
...  
named arguments to be passed by name to FUN.
Details

If `is.null(.dat)` and ... are all named numbers or matrices of the form argname = m, ms are passed to FUN by argnames. The return value is a named list provided by FUN. The arguments in ... are not included in the output.

If `is.null(.dat)` and ... are all lists of numbers or matrices of the form argname = l, FUN is Mapped across the various ls to obtain a list of named lists returned from FUN. The return value is a data frame whose rows are the top-level lists returned from FUN and whose column names are the names of the list items returned from FUN. Columns of .dat are not included in the return value.

If !`is.null(.dat)` and ... are all named character strings of the form argname = string, argnames are expected to be names of arguments to FUN, and strings are expected to be column names in .dat. The return value is .dat with additional columns (at right) whose names are the names of list items returned from FUN. When .dat contains columns whose names are same as columns added at the right, a warning is emitted.

.dat can be a list of named items in which case a list will be returned.

If items in .dat have same names are arguments to FUN, it is not necessary to specify any arguments in .... matsindf_apply assumes that the appropriately-named items in .dat are intended to be arguments to FUN. When an item name appears in both ... and .dat, ... takes precedence.

NULL arguments in ... are ignored for the purposes of deciding whether all arguments are numbers, matrices, lists of numbers of matrices, or named character strings. However, all NULL arguments are passed to FUN, so FUN should be able to deal with NULL arguments appropriately.

If .dat is present, ... contains strings, and one of the ... strings is not the name of a column in .dat, FUN is called WITHOUT the argument whose column is missing. I.e., that argument is treated as missing. If FUN works despite the missing argument, execution proceeds. If FUN cannot handle the missing argument, an error will occur in FUN.

Value

a named list or a data frame. (See details.)

Examples

library(matsbyname)
example_fun <- function(a, b){
  return(list(c = sum_byname(a, b), d = difference_byname(a, b)))
}
# Single values for arguments
matsindf_apply(FUN = example_fun, a = 2, b = 2)
# Matrices for arguments
a <- 2 * matrix(c(1,2,3,4), nrow = 2, ncol = 2, byrow = TRUE, 
dimnames = list(c("r1", "r2"), c("c1", "c2")))
b <- 0.5 * a
matsindf_apply(FUN = example_fun, a = a, b = b)
# Single values in lists are treated like columns of a data frame
matsindf_apply(FUN = example_fun, a = list(2, 2), b = list(1, 2))
# Matrices in lists are treated like columns of a data frame
matsindf_apply(FUN = example_fun, a = list(a, a), b = list(b, b))
# Single numbers in a data frame
DF <- data.frame(a = c(4, 4, 5), b = c(4, 4, 4))
matsindf_apply_types

This is a convenience function that returns a logical list for the types of ... with components named dots_present, all_dots_num, all_dots_mats, all_dots_list, all_dots_vect, and all_dots_char.

Usage

matsindf_apply_types(...)

Arguments

... the list of arguments to be checked

Details

When arguments are present in ..., dots_present is TRUE but FALSE otherwise. When all items in ... are single numbers, all_dots_num is TRUE and all other list members are FALSE. When all items in ... are matrices, all_dots_mats is TRUE and all other list members are FALSE. When all items in ... are lists, all_dots_list is TRUE and all other list members are FALSE. When all items in ... are vectors (including lists), all_dots_vect is TRUE. When all items in ... are character strings, all_dots_char is TRUE and all other list members are FALSE.

Value

A logical list with components named dots_present, all_dot_num, all_dots_mats, all_dots_list, and all_dots_char.
Examples

mat_to_rowcolval(a = 1, b = 2)
matsindf_apply_types(a = matrix(c(1, 2)), b = matrix(c(3, 4)))
matsindf_apply_types(a = c(1, 2), b = c(3, 4), c = c(5, 6))
matsindf_apply_types(a = list(1, 2), b = list(3, 4), c = list(5, 6))
matsindf_apply_types(a = "a", b = "b", c = "c")

Description

This function "expands" a matrix into a tidy data frame with a values column and factors for row names, column names, row types, and column types. Optionally, values can be dropped.

Usage

mat_to_rowcolval(
  .matrix, 
  matvals = "matvals", 
  rownames = "rownames", 
  colnames = "colnames", 
  rowtypes = "rowtypes", 
  coltypes = "coltypes", 
  drop = NA 
)

Arguments

.matrix the IO-style matrix to be converted to a data frame with rows, columns, and values
matvals a string for the name of the output column containing values. Default is "matvals".
rownames a string for the name of the output column containing row names. Default is "rownames".
colnames a string for the name of the output column containing column names. Default is "colnames".
rowtypes a string for the name of the output column containing row types. Default is "rowtypes".
coltypes a string for the name of the output column containing column types. Default is "coltypes".
drop if specified, the value to be dropped from output. Default is NA. For example, drop = 0 will cause 0 entries in the matrices to be deleted from output. If NA, no values are dropped from output.
## Value

a data frame with rows, columns, and values

## Examples

```r
library(matsbyname)
data <- data.frame(  
  Country = c("GH", "GH", "GH"),  
  rows = c("c1", "c1", "c2"),  
  cols = c("i1", "i2", "i2"),  
  rt = c("Commodities", "Commodities", "Commodities"),  
  ct = c("Industries", "Industries", "Industries"),  
  vals = c(11, 12, 22)  
)
data
A <- data %>%  
  rowcolval_to_mat(rownames = "rows", colnames = "cols",  
                    rowtypes = "rt", coltypes = "ct", matvals = "vals")
A
mat_to_rowcolval(A, rownames = "rows", colnames = "cols",  
                 rowtypes = "rt", coltypes = "ct", matvals = "vals")
mat_to_rowcolval(A, rownames = "rows", colnames = "cols",  
                 rowtypes = "rt", coltypes = "ct", matvals = "vals", drop = 0)
# This also works for single values
mat_to_rowcolval(2, matvals = "vals",  
                 rownames = "rows", colnames = "cols",  
                 rowtypes = "rt", coltypes = "ct")
mat_to_rowcolval(0, matvals = "vals",  
                 rownames = "rows", colnames = "cols",  
                 rowtypes = "rt", coltypes = "ct", drop = 0)
```

---

**rowcolval_to_mat**  
**Collapse a tidy data frame into a matrix with named rows and columns**

## Description

Columns not specified in one of rownames, colnames, rowtype, coltype, or values are silently dropped. rowtypes and coltypes are added as attributes to the resulting matrix (via `setrowtype` and `setcoltype`). The resulting matrix is a (under the hood) a data frame. If both rownames and colnames columns of `.DF` contain NA, it is assumed that this is a single value, not a matrix, in which case the value in the values column is returned.

## Usage

```r
rowcolval_to_mat(  
  .DF,  
  matvals = "matvals",  
  rownames = "rownames",  
  colnames = "colnames",  
  rowtypes = "rowtypes",  
  coltypes = "coltypes")
```
Arguments

- **.DF**
a tidy data frame containing columns for row names, column names, and values
- **matvals**
  the name of the column in .DF containing values with which to fill the matrix (a string). Default is "matvals".
- **rownames**
  the name of the column in .DF containing row names (a string). Default is "rownames".
- **colnames**
  the name of the column in .DF containing column names (a string). Default is "colnames".
- **rowtypes**
  an optional string identifying the types of information found in rows of the matrix to be constructed. Default is "rowtypes".
- **coltypes**
  an optional string identifying the types of information found in columns of the matrix to be constructed. Default is "coltypes".
- **fill**
  the value for missing entries in the resulting matrix. default is 0.

Value

a matrix with named rows and columns and, optionally, row and column types

Examples

```r
library(matsbyname)
library(dplyr)
data <- data.frame(Country = c("GH", "GH", "GH"),
                   rows = c("c 1", "c 1", "c 2"),
                   cols = c("i 1", "i 2", "i 2"),
                   vals = c(11, 12, 22))
A <- rowcolval_to_mat(data, rownames = "rows", colnames = "cols", matvals = "vals")
A
rowtype(A) # NULL, because types not set
coltype(A) # NULL, because types not set
B <- rowcolval_to_mat(data, rownames = "rows", colnames = "cols", matvals = "vals",
                      rowtypes = "Commodities", coltypes = "Industries")
B

---

**UKEnergy2000**

**Energy consumption in the UK in 2000**

---

**Description**

**Usage**

UKEnergy2000

**Format**

A data frame with 36 rows and 7 variables:

- **Country** country, GB (Great Britain, only one country)
- **Year** year, 2000 (only one year)
- **Ledgerside** Supply or Consumption
- **Flow.aggregation.point** tells where each row should be aggregated
- **Flow** the Industry or Sector involved in this flow
- **Product** the energy product involved in this flow
- **E.ktoe** magnitude of the energy flow in ktoe

verify_cols_missing

Verify that column names in a data frame are not already present

Description

In the Recca package, many functions add columns to an existing data frame. If the incoming data frame already contains columns with the names of new columns to be added, a name collision could occur, deleting the existing column of data. This function provides a way to quickly check whether newcols are already present in .DF.

Usage

```
verify_cols_missing(.DF, newcols)
```

Arguments

- `.DF` the data frame to which newcols are to be added
- `newcols` a single string, a single name, a vector of strings representing the names of new columns to be added to .DF, or a vector of names of new columns to be added to .DF

Details

This function terminates execution if a column of .DF will be overwritten by one of the newcols.

Value

`NULL`. This function should be called for its side effect of checking the validity of the names of newcols to be added to .DF.

Examples

```
df <- data.frame(a = c(1,2), b = c(3,4))
verify_cols_missing(df, "d") # Silent. There will be no problem adding column "d".
newcols <- c("c", "d", "a", "b")
## Not run: verify_cols_missing(df, newcols) # Error: a and b are already in df.
```
