Package ‘nflseedR’

April 10, 2021

Title Functions to Efficiently Simulate and Evaluate NFL Seasons

Version 1.0.2

Description A set of functions to simulate National Football League seasons including the sophisticated tie-breaking procedures.

License MIT + file LICENSE

BugReports https://github.com/leesharpe/nflseedR/issues

Depends R (>= 3.5.0)

Imports cli, crayon, curl, dplyr, furrr, future, glue, gsubfn, magrittr, progressr, purrr, readr, rlang, tibble, tidyr

Suggests knitr, rmarkdown, testthat (>= 3.0.0), tidyverse

Config/testthat/edition 3

Encoding UTF-8

LazyData true

RoxygenNote 7.1.1

NeedsCompilation no

compute_conference_seeds

Description
Compute NFL Playoff Seedings using Game Results and Divisional Rankings

Usage
compute_conference_seeds(
  teams,
  h2h = NULL,
  tiebreaker_depth = 3,
  .debug = FALSE,
  playoff_seeds = 7
)

Arguments
- **teams**: The division standings data frame as computed by `compute_division_ranks`.
- **h2h**: A data frame that is used for head-to-head tiebreakers across the tie-breaking functions. It is computed by the function `compute_division_ranks`.
- **tiebreaker_depth**: A single value equal to 1, 2, or 3. The default is 3. The value controls the depth of tiebreakers that shall be applied. The deepest currently implemented tiebreaker is strength of schedule. The following values are valid:
  - `tiebreaker_depth = 1`: Break all ties with a coinflip. Fastest variant.
  - `tiebreaker_depth = 2`: Apply head-to-head and division win percentage tiebreakers. Random if still tied.
  - `tiebreaker_depth = 3`: Apply all tiebreakers through strength of schedule. Random if still tied.
- **.debug**: Either TRUE or FALSE. Controls whether additional messages are printed to the console showing what the tie-breaking algorithms are currently performing.
- **playoff_seeds**: Number of playoff teams per conference (increased in 2020 from 6 to 7).

Value
A data frame of division standings including playoff seeds and the week in which the season ended for the respective team (`exit`).
A list of two data frames:
- **standings**: Division standings including playoff seeds.
- **h2h**: A data frame that is used for head-to-head tiebreakers across the tie-breaking functions.
**compute_division_ranks**

**Examples**

```r
# Change some options for better output
old <- options(list(digits = 3, tibble.print_min = 64))
library(dplyr, warn.conflicts = FALSE)

nflseedR::load_sharpe_games() %>%
  dplyr::filter(season %in% 2019:2020) %>%
  dplyr::select(sim = season, game_type, week, away_team, home_team, result) %>%
  nflseedR::compute_division_ranks() %>%
  nflseedR::compute_conference_seeds(h2h = .$h2h) %>%
  purrr::pluck("standings")

# Restore old options
options(old)
```

---

**compute_division_ranks**

*Compute NFL Division Rankings using Game Results*

**Description**

Compute NFL Division Rankings using Game Results

**Usage**

```r
compute_division_ranks(
  games,
  teams = NULL,
  tiebreaker_depth = 3,
  .debug = FALSE,
  h2h = NULL
)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>games</td>
<td>A data frame containing real or simulated game scores. The following variables are required:</td>
</tr>
<tr>
<td>sim</td>
<td>A simulation ID. Normally 1 - n simulated seasons.</td>
</tr>
<tr>
<td>game_type</td>
<td>One of 'REG', 'WC', 'DIV', 'CON', 'SB' indicating if a game was a regular season game or one of the playoff rounds.</td>
</tr>
<tr>
<td>week</td>
<td>The week of the corresponding NFL season.</td>
</tr>
</tbody>
</table>
away_team Team abbreviation of the away team (please see divisions for valid team abbreviations).

home_team Team abbreviation of the home team (please see divisions for valid team abbreviations).

result Equals home score - away score.

team This parameter is optional. If it is NULL the function will compute it internally, otherwise it has to be a data frame of all teams contained in the games data frame repeated for each simulation ID (sim). The following variables are required:

sim A simulation ID. Normally 1 - n simulated seasons.

team Team abbreviation of the team (please see divisions for valid team abbreviations).

conf Conference abbreviation of the team (please see divisions for valid team abbreviations).

division Division of the team (please see divisions for valid division names).

tiebreaker_depth A single value equal to 1, 2, or 3. The default is 3. The value controls the depth of tiebreakers that shall be applied. The deepest currently implemented tiebreaker is strength of schedule. The following values are valid:

tiebreaker_depth = 1 Break all ties with a coinflip. Fastest variant.

tiebreaker_depth = 2 Apply head-to-head and division win percentage tiebreakers. Random if still tied.

tiebreaker_depth = 3 Apply all tiebreakers through strength of schedule. Random if still tied.

.debug Either TRUE or FALSE. Controls whether additional messages are printed to the console showing what the tie-breaking algorithms are currently performing.

h2h A data frame that is used for head-to-head tiebreakers across the tie-breaking functions. It is computed by the function compute_division_ranks.

Value

A list of two data frames:

standings Division standings.

h2h A data frame that is used for head-to-head tiebreakers across the tie-breaking functions.

Examples

# Change some options for better output
old <- options(list(digits = 3, tibble.print_min = 64))
library(dplyr, warn.conflicts = FALSE)
nflseedR::load_sharpe_games() %>%

compute_division_ranks
compute_draft_order

```r
dplyr::filter(season %in% 2019:2020) %>%
dplyr::select(sim = season, game_type, week, away_team, home_team, result) %>%
nflseedR::compute_division_ranks() %>%
purrr::pluck("standings")

# Restore old options
options(old)
```

**compute_draft_order**  
*Compute NFL Draft Order using Game Results and Divisional Rankings*

**Description**  
Compute NFL Draft Order using Game Results and Divisional Rankings

**Usage**

```r
compute_draft_order(
  teams,
  games,
  h2h = NULL,
  tiebreaker_depth = 3,
  .debug = FALSE
)
```

**Arguments**

- **teams**  
The division standings data frame including playoff seeds as computed by `compute_conference_seeds`.

- **games**  
A data frame containing real or simulated game scores. The following variables are required:
  - **sim**  
    A simulation ID. Normally 1 - n simulated seasons.
  - **game_type**  
    One of 'REG', 'WC', 'DIV', 'CON', 'SB' indicating if a game was a regular season game or one of the playoff rounds.
  - **week**  
    The week of the corresponding NFL season.
  - **away_team**  
    Team abbreviation of the away team (please see `divisions` for valid team abbreviations).
  - **home_team**  
    Team abbreviation of the home team (please see `divisions` for valid team abbreviations).
  - **result**  
    Equals home score - away score.

- **h2h**  
A data frame that is used for head-to-head tiebreakers across the tie-breaking functions. It is computed by the function `compute_division_ranks`.

- **tiebreaker_depth**  
A single value equal to 1, 2, or 3. The default is 3. The value controls the depth of tiebreakers that shall be applied. The deepest currently implemented tiebreaker is strength of schedule. The following values are valid:
tiebreaker_depth = 1  Break all ties with a coinflip. Fastest variant.
tiebreaker_depth = 2  Apply head-to-head and division win percentage tiebreakers. Random if still tied.
tiebreaker_depth = 3  Apply all tiebreakers through strength of schedule. Random if still tied.

Value

A data frame of standings including the final draft pick number and the variable exit which indicates the week number of the teams final game (Super Bowl Winner is one week higher).

divisions  

NFL team names and the conferences and divisions they belong to

description

NFL team names and the conferences and divisions they belong to

usage

divisions
**Format**

A data frame with 36 rows and 4 variables containing NFL team level information, including franchises in multiple cities:

- **team**: Team abbreviation
- **conf**: Conference abbreviation
- **division**: Division name
- **sdiv**: Division abbreviation

This data frame is created using the `teams_colors_logos` data frame of the `nflfastR` package. Please see `data-raw/divisions.R` for the code to create this data.

**Examples**

```r
divisions
```

---

**Description**

Lee Sharpe maintains an important data set that contains broadly used information on games in the National Football League. This function is a convenient helper to download the file into memory without having to remember the correct url.

**Usage**

```r
load_sharpe_games()
```

**Value**

A data frame containing the following variables for all NFL games since 1999:

- **game_id**: The ID of the game as assigned by the NFL. Note that this value matches the `game_id` field in `nflscrapR` if you wish to join the data.
- **season**: The year of the NFL season. This represents the whole season, so regular season games that happen in January as well as playoff games will occur in the year after this number.
- **game_type**: What type of game? One of the following values:
  - REG: a regular season game
  - WC: a wildcard playoff game
  - DIV: a divisional round playoff game
  - CON: a conference championship
  - SB: a Super Bowl
**week**  The week of the NFL season the game occurs in. This will be 1-17 for the regular season, 18 for wildcard playoff games, 19 for divisional playoff games, 20 for conference championships and 21 for Super Bowls.

**gameday**  The date on which the game occurred.

**weekday**  The day of the week on which the game occurred.

**gametime**  The kickoff time of the game. This is represented in 24-hour time and the Eastern time zone, regardless of what time zone the game was being played in.

**away_team**  The away team.

**away_score**  The number of points the away team scored. Is NA for games which haven’t yet been played.

**home_team**  The home team. Note that this contains the designated home team for games which no team is playing at home such as Super Bowls or NFL International games.

**home_score**  The number of points the home team scored. Is NA for games which haven’t yet been played.

**location**  Either Home if the home team is playing in their home stadium, or Neutral if the game is being played at a neutral location. This still shows as Home for games between the Giants and Jets even though they share the same home stadium.

**result**  Equals home_score - away_score. The number of points the home team scored minus the number of points the away team scored. Is NA for games which haven’t yet been played. Convenient for evaluating against the spread bets.

**total**  The sum of each team’s score in the game. Equals home_score + away_score. Is NA for games which haven’t yet been played. Convenient for evaluating over/under total bets.

**overtime**  Whether the game went into overtime (= 1) or not (= 0).

**old_game_id**  The id of the game issued by the NFL Game Statistics & Information System.

**away_rest**  The number of days since that away team’s previous game (7 is used for the team’s first game of the season).

**home_rest**  The number of days since that home team’s previous game (7 is used for the team’s first game of the season).

**away_moneyline**  Odd of the away_team winning the game.

**home_moneyline**  Odd of the home_team winning the game.

**spread_line**  The spread line for the game. A positive number means the home team was favored by that many points, a negative number means the away team was favored by that many points. This lines up with the result column.

**away_spread_odds**  Odd of the away_team covering the spread_line.

**home_spread_odds**  Odd of the home_team covering the spread_line.

**total_line**  The total line for the game.

**under_odds**  Odd of the total being under the total_line.

**over_odds**  Odd of the total being over the total_line.

**div_game**  Whether the game was a divisional game (= 1) or not (= 0).

**roof**  What was the status of the stadium’s roof? Will be one of the following values:
  - closed: Stadium has a retractable roof which was closed
simulate_nfl

- dome: An indoor stadium
- open: Stadium has a retractable roof which was open
- outdoors: An outdoor stadium

**surface**  What type of ground the game was played on.

**temp**  The temperature at the stadium (for roof types outdoors and open only).

**wind**  The speed of the wind in miles/hour (for roof types outdoors and open only).

**away_qb_id**  GSIS ID of the "starting quarterback" of the away team identified as the first quarterback (per roster data) listed as passer (in nflfastR play by play data) in 2+ plays that game. In the final regular season game it is the QB with the most plays as the passer.

**home_qb_id**  GSIS ID of the "starting quarterback" of the home team identified as the first quarterback (per roster data) listed as passer (in nflfastR play by play data) in 2+ plays that game. In the final regular season game it is the QB with the most plays as the passer.

**away_qb_name**  Full name of the "starting quarterback" of the away team identified as the first quarterback (per roster data) listed as passer (in nflfastR play by play data) in 2+ plays that game. In the final regular season game it is the QB with the most plays as the passer.

**home_qb_name**  Full name of the "starting quarterback" of the home team identified as the first quarterback (per roster data) listed as passer (in nflfastR play by play data) in 2+ plays that game. In the final regular season game it is the QB with the most plays as the passer.

**away_coach**  Name of the head coach of the away team.

**home_coach**  Name of the head coach of the home team.

**referee**  Name of the game’s referee (head official).

**stadium_id**  Pro Football Reference ID of the stadium.

**stadium**  Name of the stadium.

**Examples**

```r
  games <- load_sharpe_games()
  dplyr::glimpse(games)
```

**simulate_nfl**  *Simulate an NFL Season*

**Description**

This function simulates a given NFL season multiple times using custom functions to estimate and simulate game results and computes the outcome of the given season including playoffs and draft order. It is possible to run the function in parallel processes by calling the appropriate plan. Progress updates can be activated by calling handlers before the start of the simulations. Please see the below given section "Details" for further information.
Usage

```r
simulate_nfl(
    nfl_season = NULL,
    process_games = NULL,
    ..., 
    playoff_seeds = ifelse(nfl_season >= 2020, 7, 6),
    if_ended_today = FALSE,
    fresh_season = FALSE,
    fresh_playoffs = FALSE,
    tiebreaker_depth = 3,
    test_week = NULL,
    simulations = 1000,
    sims_per_round = max(ceiling(simulations/future::availableCores() * 2), 100),
    .debug = FALSE,
    print_summary = FALSE
)
```

Arguments

- `nfl_season` Season to simulate
- `process_games` A function to estimate and simulate the results of games. Uses team, schedule, and week number as arguments.
- `...` Additional parameters passed on to the function `process_games`.
- `playoff_seeds` Number of playoff teams per conference (increased in 2020 from 6 to 7).
- `if_ended_today` Either `TRUE` or `FALSE`. If `TRUE`, ignore remaining regular season games and cut to playoffs based on current regular season data.
- `fresh_season` Either `TRUE` or `FALSE`. Whether to blank out all game results and simulate the season from scratch (`TRUE`) or take game results so far as a given and only simulate the rest (`FALSE`).
- `fresh_playoffs` Either `TRUE` or `FALSE`. Whether to blank out all playoff game results and simulate the postseason from scratch (`TRUE`) or take game results so far as a given and only simulate the rest (`FALSE`).
- `tiebreaker_depth` A single value equal to 1, 2, or 3. The default is 3. The value controls the depth of tiebreakers that shall be applied. The deepest currently implemented tiebreaker is strength of schedule. The following values are valid:
  - `tiebreaker_depth = 1` Break all ties with a coinflip. Fastest variant.
  - `tiebreaker_depth = 2` Apply head-to-head and division win percentage tiebreakers. Random if still tied.
  - `tiebreaker_depth = 3` Apply all tiebreakers through strength of schedule. Random if still tied.
- `test_week` Aborts after the simulator reaches this week and returns the results from your process games call.
- `simulations` Equals the number of times the given NFL season shall be simulated.
simulate_nfl

sims_per_round  The number of simulations can be split into multiple rounds and be processed parallel. This parameter controls the number of simulations per round. The default value determines the number of locally available cores and calculates the number of simulations per round to be equal to half of the available cores (various benchmarks showed this results in optimal performance).

debg  Either TRUE or FALSE. Controls whether additional messages are printed to the console showing what the tie-breaking algorithms are currently performing.

print_summary  If TRUE, prints the summary statistics to the console.

Details

More Speed Using Parallel Processing:
We recommend choosing a default parallel processing method and saving it as an environment variable in the R user profile to make sure all futures will be resolved with the chosen method by default. This can be done by following the below given steps.
First, run the following line and the user profile should be opened automatically. If you haven’t saved any environment variables yet, this will be an empty file.

usethis::edit_r_environ()

In the opened file add the next line, then save the file and restart your R session. Please note that this example sets "multisession" as default. For most users this should be the appropriate plan but please make sure it truly is.

R_FUTURE_PLAN="multisession"

After the session is freshly restarted please check if the above method worked by running the next line. If the output is FALSE you successfully set up a default non-sequential future::plan(). If the output is TRUE all functions will behave like they were called with purrr::map() and NOT in multisession.

inherits(future::plan(), "sequential")

For more information on possible plans please see the future package Readme.

Get Progress Updates while Functions are Running:
Most nflfastR functions are able to show progress updates using progressr::progressor() if they are turned on before the function is called. There are at least two basic ways to do this by either activating progress updates globally (for the current session) with

progressr::handlers(global = TRUE)

or by piping the function call into progressr::with_progress():

simulate_nfl(2020, fresh_season = TRUE) %>%
progressr::with_progress()

For more information how to work with progress handlers please see progressr::progressr.

Value

A list of 4 data frames with the results of all simulated games, the final standings in each simulated season (incl. playoffs and draft order) and summary statistics across all simulated seasons. For a full list, please see the package website.
Simulate NFL

Examples

```r
library(nflseedR)

# Activate progress updates
# progressr::handlers(global = TRUE)

# Parallel processing can be activated via the following line
# future::plan("multisession")

# Simulate the season 4 times in 2 rounds
sim <- nflseedR::simulate_nfl(
  nfl_season = 2020,
  fresh_season = TRUE,
  simulations = 4,
  sims_per_round = 2
)

# Overview output
dplyr::glimpse(sim)
```
