

Package ‘pedtools’

May 25, 2023

Type Package

Title Creating and Working with Pedigrees and Marker Data

Version 2.2.0

Description A comprehensive collection of tools for creating, manipulating and visualising pedigrees and genetic marker data. Pedigrees can be read from text files or created on the fly with built-in functions. A range of utilities enable modifications like adding or removing individuals, breaking loops, and merging pedigrees. An online tool for creating pedigrees interactively, based on 'pedtools', is available at <<https://magnusdv.shinyapps.io/quickped>>. 'pedtools' is the hub of the 'ped suite', a collection of packages for pedigree analysis. A detailed presentation of the 'ped suite' is given in the book 'Pedigree Analysis in R' (Vigeland, 2021, ISBN:9780128244302).

addAllele *Add allele*

Description

Extends the allele set of a marker attached to a pedigree, by adding a single allele.

Usage

```
addAllele(x, marker, allele, freq = 0.001, adjust = c("previous", "all"))
```

Arguments

x	A ped object or a list of such, or a frequency database (list of numeric vectors).
marker	The name or index of a marker attached to x.
allele	The name of the new allele.
freq	The frequency of the new allele, by default 0.001.
adjust	Either "previous" or "all", indicating how the frequencies should be adjusted so that they sum to 1. If "previous" (default), the frequencies of the original alleles are multiplied with 1 - freq. If "all", scaling is performed after adding the new allele, i.e., dividing all frequencies by 1 + freq.

Value

A copy of x with modified marker attributes.

Examples

```
## Ped input
x = nuclearPed() |>
  addMarker(geno = c(NA, NA, "b/c"), afreq = c(b = 0.5, c = 0.5))

y = addAllele(x, marker = 1, allele = "a")
afreq(y, 1)

z = addAllele(y, marker = 1, allele = "d", freq = 0.1, adjust = "all")
afreq(z, 1)
```

```
## Database input
db = list(M1 = c(a = .2, b = .3, c = .5),
          M2 = c("7" = .9, "8.3" = .1))
addAllele(db, marker = "M2", allele = "8")
```

as.data.frame.ped *Convert ped to data.frame*

Description

Convert a ped object to a data.frame. The first columns are id, fid, mid and sex, followed by genotype columns for all (or a selection of) markers.

Usage

```
## S3 method for class 'ped'
as.data.frame(x, ..., markers, sep = "/", missing = "-")
```

Arguments

x	Object of class ped.
...	Further parameters
markers	Vector of marker names or indices. By default, all markers are included.
sep	A single string to be used as allele separator in marker genotypes.
missing	A single string to be used for missing alleles.

Details

Note that the output of `as.data.frame.ped()` is quite different from that of `as.matrix.ped()`. This reflects the fact that these functions have different purposes.

Conversion to a data frame is primarily intended for pretty printing. It uses correct labels for pedigree members and marker alleles, and pastes alleles to form nice-looking genotypes.

The matrix method, on the other hand, is a handy tool for manipulating the pedigree structure. It produces a numeric matrix, using the internal index labelling both for individuals and alleles, making it very fast. In addition, all necessary meta information (loop breakers, allele frequencies a.s.o) is kept as attributes, which makes it possible to recreate the original ped object.

Value

A data.frame with `pedsize(x)` rows and `4 + nMarkers(x)` columns.

See Also

[as.matrix.ped\(\)](#)

as.matrix.ped	Convert ped to matrix
---------------	-----------------------

Description

Converts a ped object to a numeric matrix using internal labels, with additional info necessary to recreate the original ped attached as attributes.

Usage

```
## S3 method for class 'ped'  
as.matrix(x, include.attrs = TRUE, ...)  
  
restorePed(x, attrs = NULL, validate = TRUE)
```

Arguments

x	a ped object. In restorePed: A numerical matrix.
include.attrs	a logical indicating if marker annotations and other info should be attached as attributes. See Value.
...	not used.
attrs	a list containing labels and other ped info compatible with x, in the format produced by as.matrix. If NULL, the attributes of x itself are used.
validate	a logical, forwarded to <code>ped()</code> . If FALSE, no checks for pedigree errors are performed.

Details

restorePed is the reverse of as.matrix.ped.

Value

For as.matrix: A numerical matrix with `pedsize(x)` rows. If `include.attrs = TRUE` the following attributes are added to the matrix, allowing x to be exactly reproduced by restorePed:

- FAMID the family identifier (a string)
- LABELS the ID labels (a character vector)
- UNBROKEN_LOOPS a logical indicating whether x has unbroken loops
- LOOP_BREAKERS a numerical matrix, or NULL
- markerattr a list of length `nMarkers(x)`, containing the attributes of each marker

For restorePed: A ped object.

Author(s)

Magnus Dehli Vigeland

See Also[ped\(\)](#)**Examples**

```
x = relabel(nuclearPed(1), letters[1:3])

# To exemplify the ped -> matrix -> ped trick, we show how to
# reverse the internal ordering of the pedigree.
m = as.matrix(x, include.attrs = TRUE)
m[] = m[3:1, ]

# Must reverse the labels also:
attrs = attributes(m)
attrs$LABELS = rev(attrs$LABELS)

# Restore ped:
y = restorePed(m, attrs = attrs)

# Of course a simpler way is use reorderPed():
z = reorderPed(x, 3:1)
stopifnot(identical(y, z))
```

`as.ped`*Conversions to ped objects*

Description

Conversions to ped objects

Usage

```
as.ped(x, ...)
```

```
## S3 method for class 'data.frame'
as.ped(
  x,
  famid_col = NA,
  id_col = NA,
  fid_col = NA,
  mid_col = NA,
  sex_col = NA,
  marker_col = NA,
  locusAttributes = NULL,
  missing = 0,
  sep = NULL,
```

```

    validate = TRUE,
    ...
  )

```

Arguments

x	Any object.
...	Not used.
famid_col	Index of family ID column. If NA, the program looks for a column named "famid" (ignoring case).
id_col	Index of individual ID column. If NA, the program looks for a column named "id" (ignoring case).
fid_col	Index of father ID column. If NA, the program looks for a column named "fid" (ignoring case).
mid_col	Index of mother ID column. If NA, the program looks for a column named "mid" (ignoring case).
sex_col	Index of column with gender codes (0 = unknown; 1 = male; 2 = female). If NA, the program looks for a column named "sex" (ignoring case). If this is not found, genders of parents are deduced from the data, leaving the remaining as unknown.
marker_col	Index vector indicating columns with marker alleles. If NA, all columns to the right of all pedigree columns are used. If sep (see below) is non-NULL, each column is interpreted as a genotype column and split into separate alleles with <code>strsplit(..., split = sep, fixed = TRUE)</code> .
locusAttributes	Passed on to <code>setMarkers()</code> (see explanation there).
missing	Passed on to <code>setMarkers()</code> (see explanation there).
sep	Passed on to <code>setMarkers()</code> (see explanation there).
validate	A logical indicating if the pedigree structure should be validated.

Value

A ped object or a list of such.

Examples

```

df = data.frame(famid = c("S1", "S2"),
               id = c("A", "B"),
               fid = 0,
               mid = 0,
               sex = 1)

# gives a list of two singletons
as.ped(df)

# Trio
df1 = data.frame(id = 1:3, fid = c(0,0,1), mid = c(0,0,2), sex = c(1,2,1))

```

```

as.ped(df1)

# Disconnected example: Trio (1-3) + singleton (4)
df2 = data.frame(id = 1:4, fid = c(2,0,0,0), mid = c(3,0,0,0),
                 M = c("1/2", "1/1", "2/2", "3/4"))
as.ped(df2)

# Two singletons
df3 = data.frame(id = 1:2, fid = 0, mid = 0, sex = 1)
as.ped(df3)

```

as_kinship2_pedigree *Convert pedigree to kinship2 format*

Description

Convert pedigree to kinship2 format

Usage

```

as_kinship2_pedigree(
  x,
  deceased = NULL,
  aff = NULL,
  twins = NULL,
  hints = NULL
)

```

Arguments

x	A ped() object.
deceased	A vector of labels indicating deceased pedigree members.
aff	A vector of labels identifying members whose plot symbols should be filled. (This is typically used in medical pedigrees to indicate affected members.)
twins	A data frame with columns id1, id2 and code, passed on to the relation parameter of kinship2::plot.pedigree() .
hints	An optional list of hints passed on to kinship2::align.pedigree() .

Examples

```

x = nuclearPed()
as_kinship2_pedigree(x)

```

connectedComponents *Connected pedigree components*

Description

Compute the connected parts of a pedigree. This is an important step when converting pedigree data from other formats (where disconnected pedigrees may be allowed) to pedtools (which requires pedigrees to be connected).

Usage

```
connectedComponents(id, fid = NULL, mid = NULL, fidx = NULL, midx = NULL)
```

Arguments

id	A vector of ID labels (character or numeric).
fid	The ID labels of the fathers (or "0" if missing).
mid	The ID labels of the mothers (or "0" if missing).
fidx, midx	(For internal use mostly.) Integer vectors with paternal (resp. maternal) indices. These may be given instead of id, fid, mid.

Value

A list, where each element is a subset of id constituting a connected pedigree.

Examples

```
# A trio (1-3) and a singleton (4)
x = data.frame(id = 1:4, fid = c(2,0,0,0), mid = c(3,0,0,0))
connectedComponents(x$id, x$fid, x$mid)
```

distributeMarkers *Distribute markers evenly along a set of chromosomes*

Description

Create and attach identical (empty) marker objects, distributed along a set of chromosomes.

Usage

```
distributeMarkers(  
  x,  
  n = NULL,  
  dist = NULL,  
  chromLen = NULL,  
  alleles = 1:2,  
  afreq = NULL,  
  prefix = "M"  
)
```

Arguments

x	A ped object.
n	The total number of markers. Either this or dist must be NULL.
dist	A positive number; the distance (in megabases) between markers.
chromLen	A numeric vector indicating chromosome lengths (in Mb). By default, the lengths of the human chromosomes 1-22 are used, as returned by <code>sapply(ibdsim2::loadMap("decode"), ibdsim2::physRange)</code> .
alleles, afreq	Passed onto <code>marker()</code> .
prefix	A string used as prefix for marker names. Default: "M".

Details

Note: When using the `dist` parameter, the function treats each chromosome separately, places one marker at the start and then every `dist` megabases. (See Examples.)

Value

A copy of `x` with the indicated markers attached.

Examples

```
x = distributeMarkers(nuclearPed(), n = 10)  
getMap(x)  
  
y = distributeMarkers(nuclearPed(), dist = 100)  
getMap(y)
```

famid	<i>Family identifier</i>
-------	--------------------------

Description

Functions for getting or setting the family ID of a ped object.

Usage

```
famid(x, ...)
```

```
## S3 method for class 'ped'
```

```
famid(x, ...)
```

```
famid(x, ...) <- value
```

```
## S3 replacement method for class 'ped'
```

```
famid(x, ...) <- value
```

Arguments

x	A ped object
...	(Not used)
value	The new family ID, which must be (coercible to) a character string.

Examples

```
x = nuclearPed(1)
```

```
famid(x) # empty string
```

```
famid(x) = "trio"
```

```
famid(x)
```

founderInbreeding	<i>Inbreeding coefficients of founders</i>
-------------------	--

Description

Functions to get or set inbreeding coefficients for the pedigree founders.

Usage

```
founderInbreeding(x, ids, named = FALSE, chromType = "autosomal")
```

```
founderInbreeding(x, ids, chromType = "autosomal") <- value
```

```
setFounderInbreeding(x, ids = NULL, value, chromType = "autosomal")
```

Arguments

x	A ped object or a list of such.
ids	Any subset of founders(x). If ids is missing in founderInbreeding(), it is set to founders(x).
named	A logical: If TRUE, the output vector is named with the ID labels.
chromType	Either "autosomal" (default) or "x".
value	A numeric of the same length as ids, entries in the interval [0, 1]. If the vector is named, then the names are interpreted as ID labels of the founders whose inbreeding coefficients should be set. In this case, the ids argument should not be used. (See examples.)

Value

For founderInbreeding, a numeric vector of the same length as ids, containing the founder inbreeding coefficients.

For setFounderInbreeding(), a copy of x with modified founder inbreeding.
founderInbreeding<- is an in-place version of setFounderInbreeding().

Examples

```
x = nuclearPed(father = "fa", mother = "mo", child = 1)
founderInbreeding(x, "fa") = 1
founderInbreeding(x, named = TRUE)

# Setting all founders at once (replacement value is recycled)
founderInbreeding(x, ids = founders(x)) = 0.5
founderInbreeding(x, named = TRUE)

# Alternative syntax, using a named vector
founderInbreeding(x) = c(fa = 0.1, mo = 0.2)
founderInbreeding(x, named = TRUE)
```

freqDatabase

Allele frequency database

Description

Functions for reading, setting and extracting allele frequency databases, in either "list" format or "allelic ladder" format.

Usage

```

getFreqDatabase(x, markers = NULL, format = c("list", "ladder"))

setFreqDatabase(x, database, format = c("list", "ladder"), ...)

readFreqDatabase(filename, format = c("list", "ladder"), fixNames = FALSE, ...)

writeFreqDatabase(x, filename, markers = NULL, format = c("list", "ladder"))

```

Arguments

x	A ped object, or a list of such.
markers	A character vector (with marker names) or a numeric vector (with marker indices).
format	Either "list" or "ladder".
database	Either a list or matrix/data frame with allele frequencies, or a file path (to be passed on to readFreqDatabase()).
...	Optional arguments passed on to read.table() .
filename	The path to a text file containing allele frequencies either in "list" or "allelic ladder" format.
fixNames	A logical (default: FALSE). If TRUE all marker names are converted to upper case and "." and space characters are replaced with "_" (underscore).

Details

A frequency database in "list" format is a list of numeric vectors; each vector named with the allele labels, and the list itself named with the marker names.

Text files containing frequencies in "list" format should look as follows, where "marker1" and "marker2" are marker names, and "a1", "a2", ... are allele labels (which may be characters or numeric, but will always be converted to characters):

```

marker1
a1 0.2
a2 0.5
a3 0.3

marker2
a1 0.9
a2 0.1

```

A database in "allelic ladder" format is rectangular, i.e., a numeric matrix (or data frame), with allele labels as row names and markers as column names. NA entries correspond to unobserved alleles.

Value

- getFreqDatabase: either a list (if format = "list") or a data frame (if format = "ladder")
- readFreqDatabase: a list (also if format = "ladder") of named numeric vectors
- setFreqDatabase: a modified version of x

See Also

[setLocusAttributes\(\)](#), [setMarkers\(\)](#), [setAlleles\(\)](#)

Examples

```
loc1 = list(name = "m1", afreq = c(a = .1, b = .9))
loc2 = list(name = "m2", afreq = c("1" = .2, "10.2" = .3, "3" = .5))
x = setMarkers(singleton(1), locus = list(loc1, loc2))
db = getFreqDatabase(x)
db

y = setFreqDatabase(x, database = db)
stopifnot(identical(x, y))

# The database can also be read directly from file
tmp = tempfile()
write("m1\na 0.1\nb 0.9\nnm2\n1 0.2\n3 0.5\n10.2 0.3", tmp)

z = setFreqDatabase(x, database = tmp)
stopifnot(all.equal(x, z))
```

getAlleles

Allele matrix manipulation

Description

Functions for getting and setting the genotypes of multiple individuals/markers simultaneously

Usage

```
getAlleles(x, ids = NULL, markers = NULL)
```

```
setAlleles(x, ids = NULL, markers = NULL, alleles)
```

Arguments

x	A ped object or a list of such
ids	A vector of ID labels. If NULL (default) all individuals are included.
markers	A vector of indices or names of markers attaches to x. If NULL (default) all markers are included.
alleles	A character of the same format and dimensions as the output of <code>getAlleles(x, ids, markers)</code> , or an object which can be converted by <code>as.matrix()</code> into such a matrix. See Details.

Details

If the `alleles` argument of `setAlleles()` is not a matrix, it is recycled (if necessary), and converted into a matrix of the correct dimensions. For example, setting `alleles = 0` gives a simple way of removing the genotypes of some or all individuals (while keeping the markers attached).

Value

`getAlleles()` returns a character matrix with `length(ids)` rows and $2 * \text{length}(\text{markers})$ columns. The ID labels of `x` are used as rownames, while the columns are named `<m1>.1`, `<m1>.2`, ... where `<m1>` is the name of the first marker, a.s.o.

`setAlleles()` returns a ped object identical to `x`, except for the modified alleles. In particular, all locus attributes are unchanged.

See Also

[transferMarkers\(\)](#)

Examples

```
# Setup: Pedigree with two markers
x = nuclearPed(1)
x = addMarker(x, `2` = "1/2", alleles = 1:2, name = "m1")
x = addMarker(x, `3` = "2/2", alleles = 1:2, name = "m2")

# Extract allele matrix
mat1 = getAlleles(x)
mat2 = getAlleles(x, ids = 2:3, markers = "m2")
stopifnot(identical(mat1[2:3, 3:4], mat2))

# Remove all genotypes
y = setAlleles(x, alleles = 0)
y

# Setting a single genotype
z = setAlleles(y, ids = "1", marker = "m2", alleles = 1:2)

# Alternative: In-place modification with `genotype()`
genotype(y, id = "1", marker = "m2") = "1/2"
stopifnot(identical(y,z))

### Manipulation of pedlist objects
s = transferMarkers(x, singleton("s"))
peds = list(x, s)

getAlleles(peds)

setAlleles(peds, ids = "s", marker = "m1", alleles = 1:2)
```

getComponent	<i>Pedigree component</i>
--------------	---------------------------

Description

Given a list of ped objects (called pedigree components), and a vector of ID labels, find the index of the component holding each individual.

Usage

```
getComponent(x, ids, checkUnique = FALSE, errorIfUnknown = FALSE)
```

Arguments

x	A list of ped objects
ids	A vector of ID labels (coercible to character)
checkUnique	If TRUE an error is raised if any element of ids occurs more than once in x. Default: FALSE.
errorIfUnknown	If TRUE, the function stops with an error if not all elements of ids are recognised as names of members in x. Default: FALSE.

Value

An integer vector of the same length as ids, with NA entries where the corresponding label was not found in any of the components.

See Also

[internalID\(\)](#)

Examples

```
x = list(nuclearPed(1), singleton(id = "A"))
getComponent(x, c(3, "A"))
```

getGenotypes	<i>Genotype matrix</i>
--------------	------------------------

Description

Extract the genotypes of multiple individuals/markers in form of a matrix.

Usage

```
getGenotypes(x, ids = NULL, markers = NULL, sep = "/", missing = "-")
```

Arguments

x	A ped object or a list of such
ids	A vector of ID labels. If NULL (default) all individuals are included.
markers	A vector of indices or names of markers attaches to x. If NULL (default) all markers are included.
sep	A single string to be used as allele separator in marker genotypes.
missing	A single string to be used for missing alleles.

Value

getGenotypes() returns a character matrix with length(ids) rows and length(markers) columns.

See Also

[getAlleles\(\)](#)

Examples

```
x = nuclearPed(1)
m1 = marker(x, `2` = "1/2", alleles = 1:2, name = "m1")
m2 = marker(x, `3` = "2/2", alleles = 1:2, name = "m2")
x = setMarkers(x, list(m1, m2))

getGenotypes(x)

### A list of pedigrees

s = transferMarkers(x, singleton("s"))
peds = list(x, s)

getGenotypes(peds)
```

<code>getMap</code>	<i>Tabulate marker positions</i>
---------------------	----------------------------------

Description

Return a map of the markers attached to a pedigree.

Usage

```
getMap(x, markers = NULL, na.action = 0, merlin = FALSE, verbose = TRUE)
```

```
setMap(x, map, matchNames = NA, ...)
```

```
hasLinkedMarkers(x)
```

Arguments

<code>x</code>	An object of class <code>ped</code> or a list of such.
<code>markers</code>	A vector of names or indices referring to markers attached to <code>x</code> . By default, all markers are included.
<code>na.action</code>	Either 0 (default), 1 or 2. (See Details.)
<code>merlin</code>	A logical mostly for internal use: If <code>TRUE</code> the function returns a matrix instead of a data frame.
<code>verbose</code>	A logical.
<code>map</code>	Either a data frame or the path to a map file. See Details regarding format.
<code>matchNames</code>	A logical; if <code>TRUE</code> , pre-existing marker names of <code>x</code> will be used to assign chromosome labels and positions from <code>map</code> .
<code>...</code>	Further arguments passed to <code>read.table()</code> .

Details

The `na.action` argument controls how missing values are dealt with:

- `na.action = 0`: Return `map` unmodified
- `na.action = 1`: Replace missing values with dummy values.
- `na.action = 2`: Remove markers with missing data.

In `setMap()`, the `map` argument should be a data frame (or file) with the following columns in order:

1. chromosome
2. marker name
3. position (Mb)

Column names are ignored, as are any columns after the first three.

Value

getMap() returns a data frame with columns CHROM, MARKER and MB.

setMap() returns x with modified marker attributes.

hasLinkedMarkers() returns TRUE if two markers are located (with set position) on the same chromosome, and FALSE otherwise.

Examples

```
x = singleton(1)
m1 = marker(x, chrom = 1, posMb = 10, name = "m1")
m2 = marker(x, chrom = 1, posMb = 11)
m3 = marker(x, chrom = 1)
x = setMarkers(x, list(m1, m2, m3))

# Compare effect of `na.action`
getMap(x, na.action = 0)
getMap(x, na.action = 1)
getMap(x, na.action = 2)

# Getting and setting map are inverses
y = setMap(x, getMap(x))
stopifnot(identical(x,y))

hasLinkedMarkers(x)
```

getSex

Get or set the sex of pedigree members

Description

Functions for retrieving or changing the sex of specified pedigree members. When used in pedigree constructions, swapSex() is usually more convenient than setSex(), since it deals with spouses automatically.

Usage

```
getSex(x, ids = NULL, named = FALSE)
```

```
setSex(x, ids = NULL, sex)
```

```
swapSex(x, ids, verbose = TRUE)
```

Arguments

x A ped object or a list of such.

ids A vector identifying members of x, or a function, in which case it is replaced with ids(x) labels. If NULL, defaults to all members of x.

named	A logical: return a named vector or not.
sex	A numeric vector with entries 1 (= male), 2 (= female) or 0 (= unknown). If ids is NULL, sex must be named with ID labels. If sex is unnamed and shorter than ids it is recycled to length(ids).
verbose	A logical: Verbose output or not.

Details

To set unknown sex, use `setSex(x, ids, sex = 0)`. Note that if a nonfounder has unknown sex the pedigree cannot be plotted in the usual way, only with `plot(x, arrows = TRUE)`.

Value

- `getSex(x, ids)` returns an integer vector of the same length as `ids`, with entries 0 (unknown), 1 (male) or 2 (female).
- `setSex(x, ids, sex)` returns a ped object similar to `x`, but where the sex of `ids` is set according to the entries of `sex`
- `swapSex(x, ids)` returns a ped object identical to `x`, but where the sex of `ids` (and their spouses) are swapped (1 <-> 2). Individuals of unknown sex are ignored.

See Also

[ped\(\)](#)

Examples

```
x = nuclearPed(father = "fa", mother = "mo", children = "ch")

stopifnot(all.equal(
  getSex(x, named = TRUE),
  c(fa = 1, mo = 2, ch = 1)
))

# Make child female
setSex(x, ids = "ch", sex = 2)

# Same, using a named vector
setSex(x, sex = c(ch = 2))

# Same, using a function (setting all leaves to be female)
setSex(x, ids = leaves, sex = 2)

# swapSex() deals with spouses automatically
swapSex(x, ids = "fa")

# setting/getting sex in a pedlist
y = list(singleton(1, sex = 2), singleton(2), singleton(3))
sx = getSex(y, named = TRUE)
y2 = setSex(y, sex = sx)
```

```
stopifnot(identical(y, y2))
```

inbreedingLoops	<i>Pedigree loops</i>
-----------------	-----------------------

Description

Functions for identifying, breaking and restoring loops in pedigrees.

Usage

```
inbreedingLoops(x)

breakLoops(x, loopBreakers = NULL, verbose = TRUE, errorIfFail = TRUE)

tieLoops(x, verbose = TRUE)

findLoopBreakers(x)

findLoopBreakers2(x, errorIfFail = TRUE)
```

Arguments

x	a <code>ped()</code> object.
loopBreakers	either NULL (resulting in automatic selection of loop breakers) or a numeric containing IDs of individuals to be used as loop breakers.
verbose	a logical: Verbose output or not?
errorIfFail	a logical: If TRUE an error is raised if the loop breaking is unsuccessful. If FALSE, the pedigree is returned unchanged.

Details

Pedigree loops are usually handled (by `pedtools` and related packages) under the hood - using the functions described here - without need for explicit action from end users. When a `ped` object `x` is created, an internal routine detects if the pedigree contains loops, in which case `x$UNBROKEN_LOOPS` is set to TRUE.

In cases with complex inbreeding, it can be instructive to plot the pedigree after breaking the loops. Duplicated individuals are plotted with appropriate labels (see examples).

The function `findLoopBreakers` identifies a set of individuals breaking all inbreeding loops, but not marriage loops. These require more machinery for efficient detection, and `pedtools` does this in a separate function, `findLoopBreakers2`, utilizing methods from the `igraph` package. Since this is rarely needed for most users, `igraph` is not imported when loading `pedtools`, only when `findLoopBreakers2` is called.

In practice, `breakLoops` first calls `findLoopBreakers` and breaks at the returned individuals. If the resulting `ped` object still has loops, `findLoopBreakers2` is called to break any marriage loops.

Value

For `breakLoops`, a `ped` object in which the indicated loop breakers are duplicated. The returned object will also have a non-null `loopBreakers` entry, namely a matrix with the IDs of the original loop breakers in the first column and the duplicates in the second. If loop breaking fails, then depending on `errorIfFail` either an error is raised, or the input pedigree is returned, still containing unbroken loops.

For `tieLoops`, a `ped` object in which any duplicated individuals (as given in the `x$LOOP_BREAKERS` entry) are merged. For any `ped` object `x`, the call `tieLoops(breakLoops(x))` should return `x`.

For `inbreedingLoops`, a list containing all inbreeding loops (not marriage loops) found in the pedigree. Each loop is represented as a list with elements `top`, `bottom`, `pathA` (individuals forming a path from top to bottom) and `pathB` (creating a different path from top to bottom, with no individuals in common with `pathA`). Note that the number of loops reported here counts all closed paths in the pedigree and will in general be larger than the genus of the underlying graph.

For `findLoopBreakers` and `findLoopBreakers2`, a numeric vector of individual ID's.

Author(s)

Magnus Dehli Vigeland

Examples

```
x = cousinPed(1, child = TRUE)
plot(breakLoops(x))

# Pedigree with marriage loop: Double first cousins
if(requireNamespace("igraph", quietly = TRUE)) {
  y = doubleCousins(1, 1, child = TRUE)
  findLoopBreakers(y) # --> 9
  findLoopBreakers2(y) # --> 7 and 9
  y2 = breakLoops(y)
  plot(y2)

  # Or loop breakers chosen by user
  y3 = breakLoops(y, 6:7)
  plot(y3)
}
```

Description

The main purpose of this page is to document the procedure and options for plotting pedigrees. Most of the arguments shown here may be supplied directly in `plot(x, ...)`, when `x` is a pedigree. See `plot.ped()` for many examples.

Usage

```
.pedAlignment(  
  x = NULL,  
  plist = NULL,  
  arrows = FALSE,  
  twins = NULL,  
  packed = TRUE,  
  width = 10,  
  align = c(1.5, 2),  
  hints = NULL,  
  ...  
)  
  
.pedAnnotation(  
  x,  
  title = NULL,  
  marker = NULL,  
  sep = "/",  
  missing = "-",  
  showEmpty = FALSE,  
  labs = labels(x),  
  col = 1,  
  fill = NA,  
  lty = 1,  
  lwd = 1,  
  hatched = NULL,  
  hatchDensity = 25,  
  aff = NULL,  
  carrier = NULL,  
  deceased = NULL,  
  starred = NULL,  
  textInside = NULL,  
  textAbove = NULL,  
  fouInb = "autosomal",  
  ...  
)  
  
.pedScaling(  
  alignment,  
  annotation,  
  cex = 1,  
  symbolsize = 1,  
  margins = 1,  
  addSpace = 0,  
  xlim = NULL,  
  ylim = NULL,  
  ...  
)
```

```
.drawPed(alignment, annotation, scaling)

.annotatePed(
  alignment,
  annotation,
  scaling,
  font = NULL,
  fam = NULL,
  col = NULL,
  colUnder = 1,
  colInside = 1,
  colAbove = 1,
  cex.main = NULL,
  font.main = NULL,
  col.main = NULL,
  ...
)
```

Arguments

<code>x</code>	A <code>ped()</code> object.
<code>plist</code>	Alignment list with format similar to <code>kinship2::align.pedigree()</code> .
<code>arrows</code>	A logical (default = FALSE). If TRUE, the pedigree is plotted as a DAG, i.e., with arrows connecting parent-child pairs.
<code>twins</code>	A data frame with columns <code>id1</code> , <code>id2</code> and <code>code</code> , passed on to the relation parameter of <code>kinship2::plot.pedigree()</code> .
<code>packed</code> , <code>width</code> , <code>align</code>	Parameters passed on to <code>kinship2::align.pedigree()</code> . Can usually be left untouched.
<code>hints</code>	An optional list of hints passed on to <code>kinship2::align.pedigree()</code> .
<code>...</code>	Further parameters passed between methods.
<code>title</code>	The plot title. If NULL (default) or "", no title is added to the plot.
<code>marker</code>	Either a vector of names or indices referring to markers attached to <code>x</code> , a marker object, or a list of such. The genotypes for the chosen markers are written below each individual in the pedigree, in the format determined by <code>sep</code> and <code>missing</code> . See also <code>showEmpty</code> . If NULL (the default), no genotypes are plotted.
<code>sep</code>	A character of length 1 separating alleles for diploid markers.
<code>missing</code>	The symbol (integer or character) for missing alleles.
<code>showEmpty</code>	A logical, indicating if empty genotypes should be included.
<code>labs</code>	A vector or function controlling the individual labels included in the plot. Alternative forms: <ul style="list-style-type: none"> • If <code>labs</code> is a vector with nonempty intersection with <code>labels(x)</code>, these individuals will be labelled. If the vector is named, then the (non-empty) names are used instead of the ID label. (See Examples.)

	<ul style="list-style-type: none"> • If <code>labs</code> is <code>NULL</code>, or has empty intersection with <code>labels(x)</code>, then no labels are drawn. • If <code>labs</code> is the word "num", then all individuals are numerically labelled following the internal ordering. • If <code>labs</code> is a function, it is replaced with <code>labs(x)</code> and handled as above. (See Examples.)
<code>col</code>	A vector or list specifying outline colours for the pedigree members. See Details for valid formats.
<code>fill</code>	A vector or list specifying fill/hatch colours for the pedigree members. See Details for valid formats. Note that if <code>fill</code> is unnamed, and either <code>aff</code> or <code>hatched</code> are given, then the fill colour is applied only to those.
<code>lty, lwd</code>	Vectors or lists specifying linetype and width of pedigree symbol outlines. See Details for valid formats.
<code>hatched</code>	A vector of labels identifying members whose plot symbols should be hatched.
<code>hatchDensity</code>	A number specifying the hatch density in lines per inch. Default: 25.
<code>aff</code>	A vector of labels identifying members whose plot symbols should be filled. (This is typically used in medical pedigrees to indicate affected members.)
<code>carrier</code>	A vector of labels identifying members whose plot symbols should be marked with a dot. (This is typically used in medical pedigrees to indicate unaffected carriers of the disease allele.)
<code>deceased</code>	A vector of labels indicating deceased pedigree members.
<code>starred</code>	A vector of labels indicating pedigree members that should be marked with a star in the pedigree plot.
<code>textInside, textAbove</code>	Character vectors of text to be printed inside or above pedigree symbols.
<code>fouInb</code>	Either "autosomal" (default), "x" or <code>NULL</code> . If "autosomal" or "x", inbreeding coefficients are added to the plot above the inbred founders. If <code>NULL</code> , or if no founders are inbred, nothing is added.
<code>alignment</code>	List of alignment details, as returned by <code>.pedAlignment()</code> .
<code>annotation</code>	List of annotation details as returned by <code>.pedAnnotation()</code> .
<code>cex</code>	Expansion factor controlling font size. This also affects symbol sizes, which by default have the width of 2.5 characters. Default: 1.
<code>symbolsize</code>	Expansion factor for pedigree symbols. Default: 1.
<code>margins</code>	A numeric indicating the plot margins. If a single number is given, it is recycled to length 4.
<code>addSpace</code>	A numeric of length 4, indicating extra padding (in inches) around the pedigree inside the plot region. Default: 0.
<code>xlim, ylim</code>	Numeric vectors of length 2, used to set <code>par("usr")</code> explicitly. Rarely needed by end users.
<code>scaling</code>	List of scaling parameters as returned by <code>.pedScaling()</code> .
<code>font, fam</code>	Arguments passed on to <code>text()</code> .
<code>colUnder, colInside, colAbove</code>	Colour vectors.
<code>cex.main, col.main, font.main</code>	Parameters passed on to <code>title()</code> .

Details

The workflow of `plot.ped(x, ...)` is approximately as follows:

```
# Calculate plot parameters
align = .pedAlignment(x, ...)
annot = .pedAnnotation(x, ...)
scale = .pedScaling(align, annot, ...)

# Produce plot
.drawPed(align, annot, scale)
.annotatePed(align, annot, scale)
```

The arguments `col`, `fill`, `lty` and `lwd` can all be indicated in a number of ways:

- An unnamed vector. This will be recycled and applied to all members. For example, `lty = 2` gives everyone a dashed outline.
- A named vector. Only pedigree members appearing in the names are affected. Example: `fill = c("1" = "red", foo = "blue")` fills individual 1 red and foo blue.
- A list of ID vectors, where the list names indicate the parameter values. Example: `col = list(red = 1:2, blue = 3:5)`.
- List entries may also be functions, taking the pedigree `x` as input and producing a vector of ID labels. The many built-in functions in [ped_subgroups](#) are particularly handy here, e.g.: `fill = list(red = founders, blue = leaves)`.

Examples

```
x = nuclearPed()

align = .pedAlignment(x)
annot = .pedAnnotation(x)
scale = .pedScaling(align, annot)

frame()
drawPed(align, annot, scale)
```

is.marker	<i>Test if something is a marker</i>
-----------	--------------------------------------

Description

Functions for testing if something is a marker object, or a list of such objects.

Usage

```
is.marker(x)
```

```
is.markerList(x)
```

Arguments

x	Any object
---	------------

Value

A logical

is.ped	<i>Is an object a ped object?</i>
--------	-----------------------------------

Description

Functions for checking whether an object is a `ped()` object, a `singleton()` or a list of such.

Usage

```
is.ped(x)
```

```
is.singleton(x)
```

```
is.pedList(x)
```

Arguments

x	Any R object.
---	---------------

Details

Note that the `singleton` class inherits from `ped`, so if `x` is a `singleton`, `is.ped(x)` returns `TRUE`.

Value

For `is.ped()`: TRUE if `x` is a ped or singleton object, otherwise FALSE.

For `is.singleton()`: TRUE if `x` is a singleton object, otherwise FALSE.

For `is.pedList()`: TRUE if `x` is a list of ped and/or singleton objects, otherwise FALSE.

Author(s)

Magnus Dehli Vigeland

See Also

[ped\(\)](#)

Examples

```
x1 = nuclearPed(1)
x2 = singleton(1)
stopifnot(is.ped(x1), !is.singleton(x1),
          is.ped(x2), is.singleton(x2),
          is.pedList(list(x1,x2)))
```

locusAttributes

Get or set locus attributes

Description

Retrieve or modify the attributes of attached markers

Usage

```
getLocusAttributes(
  x,
  markers = NULL,
  attribs = c("alleles", "afreq", "name", "chrom", "posMb", "mutmod")
)
```

```
setLocusAttributes(
  x,
  markers = NULL,
  locusAttributes,
  matchNames = NA,
  erase = FALSE
)
```

Arguments

x	A ped object, or a list of such.
markers	A character vector (with marker names) or a numeric vector (with marker indices). If NULL (default), the behaviour depends on matchNames, see Details.
attribs	A subset of the character vector c("alleles", "afreq", "name", "chrom", "posMb", "mutmod", "rate").
locusAttributes	A list of lists, with attributes for each marker.
matchNames	A logical, only relevant if markers = NULL. If TRUE, then the markers to be modified are identified by the 'name' component of each locusAttributes entry. If FALSE, all markers attached to x are selected in order.
erase	A logical. If TRUE, all previous attributes of the selected markers are erased. If FALSE, attributes not affected by the submitted locusAttributes remain untouched.

Details

The default setting markers = NULL select markers automatically, depending on the matchNames argument. If matchNames = FALSE, all markers are chosen. If matchNames = TRUE, markers will be matched against the name entries in locusAttributes (and an error issued if these are missing).

Note that the default value NA of matchNames is changed to TRUE if all entries of locusAttributes have a name component which matches the name of an attached marker.

Possible attributes given in locusAttributes are as follows (default values in parenthesis):

- alleles : a character vector with allele labels
- afreq : a numeric vector with allele frequencies (rep.int(1/L, L), where L = length(alleles))
- name : marker name (NA)
- chrom : chromosome number (NA)
- posMb : physical location in megabases (NA)
- mutmod : mutation model, or model name (NULL)
- rate : mutation model parameter (NULL)

Value

- getLocusAttributes : a list of lists
- setLocusAttributes : a modified version of x.

Examples

```
x = singleton(1)
x = addMarkers(x, marker(x, name = "m1", alleles = 1:2))
x = addMarkers(x, marker(x, name = "m2", alleles = letters[1:2], chrom = "X"))

# Change frequencies at both loci
y = setLocusAttributes(x, markers = 1:2, loc = list(afreq = c(.1, .9)))
```

```

getMarkers(y, 1)

# Set the same mutation model at both loci
z = setLocusAttributes(x, markers = 1:2, loc = list(mutmod = "proportional", rate = .1))
mutmod(z, 1)

# By default, the markers to be modified are identified by name
locs = list(list(name = "m1", alleles = 1:10),
            list(name = "m2", alleles = letters[1:10]))
w = setLocusAttributes(x, loc = locs)
getMarkers(w, 1:2)

# If `erase = TRUE` attributes not explicitly given are erased
w2 = setLocusAttributes(x, loc = locs, erase = TRUE)
chrom(w2, 2) # not "X" anymore

# The getter and setter are inverses
newx = setLocusAttributes(x, loc = getLocusAttributes(x))
stopifnot(identical(x, newx))

```

marker

Marker objects

Description

Creating a marker object associated with a pedigree. The function `marker()` returns a marker object, while `addMarker()` first creates the marker and then attaches it to `x`.

Usage

```

marker(
  x,
  ...,
  geno = NULL,
  allelematrix = NULL,
  alleles = NULL,
  afreq = NULL,
  chrom = NA,
  posMb = NA,
  name = NA,
  mutmod = NULL,
  rate = NULL,
  NAstrings = c(0, "", NA, "-"),
  validate = TRUE,
  validateMut = validate
)

addMarker(

```

```

x,
...,
geno = NULL,
allelematrix = NULL,
alleles = NULL,
afreq = NULL,
chrom = NA,
posMb = NA,
name = NA,
mutmod = NULL,
rate = NULL,
locusAttr = NULL,
NAstrings = c(0, "", NA, "-"),
validate = TRUE
)

```

Arguments

x	A ped object.
...	One or more expressions of the form <code>id = genotype</code> , where <code>id</code> is the ID label of a member of <code>x</code> , and <code>genotype</code> is a numeric or character vector of length 1 or 2 (see Examples).
geno	A character vector of length <code>pedsize(x)</code> , with genotypes written in the format "a/b".
allelematrix	A matrix with 2 columns and <code>pedsize(x)</code> rows. If this is non-NULL, then ... must be empty.
alleles	A character containing allele names. If not given, and <code>afreq</code> is named, <code>names(afreq)</code> is used. The default action is to take the sorted vector of distinct alleles occurring in <code>allelematrix</code> , <code>geno</code> or ...
afreq	A numeric of the same length as <code>alleles</code> , indicating the population frequency of each allele. A warning is issued if the frequencies don't sum to 1 after rounding to 3 decimals. If the vector is named, and <code>alleles</code> is not NULL, an error is raised if <code>setequal(names(afreq), alleles)</code> is not TRUE. If <code>afreq</code> is not specified, all alleles are given equal frequencies.
chrom	A single integer: the chromosome number. Default: NA.
posMb	A nonnegative real number: the physical position of the marker, in megabases. Default: NA.
name	A character string: the name of the marker. Default: NA.
mutmod, rate	Mutation model parameters to be passed on to <code>pedmut::mutationModel()</code> ; see there for details. Note: <code>mutmod</code> corresponds to the <code>model</code> parameter. Default: NULL (no mutation model).
NAstrings	A character vector containing strings to be treated as missing alleles. Default: <code>c("", "0", NA, "-")</code> .
validate	A logical indicating if the validity of the marker object should be checked. Default: TRUE.

validateMut	A logical indicating if the mutation model (if present) should be checked.
locusAttr	A list with names alleles, afreq, chrom, name, posMb, mutmod, rate (or a subset of these). This can be used as an alternative to entering the arguments as function parameters.

Value

An object of class marker. This is an integer matrix with 2 columns and one row per individual, and the following attributes:

- alleles (a character vector with allele labels)
- afreq (allele frequencies; default `rep.int(1/length(alleles), length(alleles))`)
- chrom (chromosome number; default = NA)
- posMb (physical location in megabases; default = NA)
- name (marker identifier; default = NA)
- mutmod (a list of two (male and female) mutation matrices; default = NULL)

See Also

Get/set marker attributes: [marker_getattr](#), [marker_setattr](#).

Retrieve various marker properties: [marker_prop](#), [nMarkers\(\)](#),

Add alleles to an existing marker: [addAllele\(\)](#)

Attach multiple markers: [marker_attach](#)

Examples

```
x = nuclearPed(father = "fa", mother = "mo", children = "child")

# An empty SNP with alleles "A" and "B"
marker(x, alleles = c("A", "B"))

# Creating and attaching to `x`
addMarker(x, alleles = c("A", "B"))

# Alleles/frequencies can be given jointly or separately
stopifnot(identical(
  marker(x, afreq = c(A = 0.01, B = 0.99)),
  marker(x, alleles = c("A", "B"), afreq = c(0.01, 0.99)),
))

# Genotypes can be assigned individually ...
marker(x, fa = "1/1", mo = "1/2")

# ... or using the `geno` vector (all members in order)
marker(x, geno = c("1/1", "1/2", NA))

# Attaching a marker to the pedigree
m = marker(x) # By default a SNP with alleles 1,2
```

```
x = setMarkers(x, m)

# A marker with a "proportional" mutation model,
# with different rates for males and females
mutrates = list(female = 0.1, male = 0.2)
marker(x, alleles = 1:2, mutmod = "prop", rate = mutrates)
```

marker_attach *Attach markers to pedigrees*

Description

In many applications it is useful to *attach* markers to their associated ped object. In particular for bigger projects with many markers, this makes it easier to manipulate the dataset as a unit. The function `setMarkers()` replaces all existing markers with the supplied ones, while `addMarkers()` appends the supplied markers to any existing ones. Note that there is also the function `addMarker()`, which creates and attaches a single marker in one go.

Usage

```
setMarkers(
  x,
  m = NULL,
  alleleMatrix = NULL,
  locusAttributes = NULL,
  missing = 0,
  sep = NULL,
  checkCons = TRUE
)

addMarkers(
  x,
  m = NULL,
  alleleMatrix = NULL,
  locusAttributes = NULL,
  missing = 0,
  sep = NULL,
  checkCons = TRUE
)
```

Arguments

<code>x</code>	A ped object
<code>m</code>	Either a single marker object or a list of marker objects
<code>alleleMatrix</code>	A matrix with <code>pedsize(x)</code> rows, containing the observed alleles for one or several markers. The matrix must have either 1 or 2 columns per marker. If the former, then a <code>sep</code> string must be a given, and will be used to split all entries.

locusAttributes	A list of lists, with attributes for each marker. See Details for possible attributes.
missing	A single character (or coercible to one) indicating the symbol for missing alleles.
sep	If this is a single string, each entry of <code>alleleMatrix</code> is interpreted as a genotype, and will be split by calling <code>strsplit(..., split = sep, fixed = TRUE)</code> . If <code>alleleMatrix</code> contains entries with <code>"/"</code> , this will be taken as separator by default. (To override this behaviour, put <code>sep = FALSE</code> .)
checkCons	A logical. If TRUE (default), each marker is checked for consistency with <code>x</code> .

Details

The most general format of `locusAttributes` a list of lists, one for each marker, where possible entries in the inner lists are as follows (default values in parenthesis):

- `alleles` : a character vector with allele labels
- `afreq` : a numeric vector with allele frequencies (`rep.int(1/L, L)`, where `L = length(alleles)`)
- `chrom` : chromosome number (NA)
- `posMb` : physical location in megabases (NA)
- `name` : marker name (NA)
- `mutmod` : mutation model, or model name (NULL)
- `rate` : mutation model parameter (NULL)

If `locusAttributes` is a single list of attributes (not a list of lists), then it is repeated to match the number of markers.

Alternative formats of `locusAttributes`::

- data frame or matrix. In this case an attempt is made to interpret it as a frequency database in allelic ladder format.
- A list of frequency vectors. All vectors should sum to 1, and be named (with allele labels)
- Shortcut for simple SNP data: The argument `locusAttributes = "snp-AB"` sets all markers to be equifrequent SNPs with alleles A and B. The letters A and B may be replaced by other single-character letters or numbers.

Value

A ped object.

See Also

[addMarker\(\)](#)

Examples

```
x = singleton(1)
m1 = marker(x, `1` = "1/2")
m2 = marker(x, `1` = "a/b")

# Attach to x
```

```

x1 = setMarkers(x, list(m1, m2))

# Reversing the order of the markers
setMarkers(x, list(m2, m1))

# Alternative syntax, adding one marker at a time
x2 = x |>
  addMarker(`1` = "1/2") |>
  addMarker(`1` = "a/b")

stopifnot(identical(x1, x2))

```

marker_getattr	<i>Get marker attributes</i>
----------------	------------------------------

Description

S3 methods retrieving marker attributes. They work on single marker objects and markers attached to ped objects (or lists of such).

Usage

```

genotype(x, ...)

## S3 method for class 'marker'
genotype(x, id, ...)

## S3 method for class 'ped'
genotype(x, markers = NULL, id, ...)

mutmod(x, ...)

## S3 method for class 'marker'
mutmod(x, ...)

## S3 method for class 'ped'
mutmod(x, marker, ...)

## S3 method for class 'list'
mutmod(x, marker, ...)

alleles(x, ...)

## S3 method for class 'marker'
alleles(x, ...)

## S3 method for class 'ped'

```

```
alleles(x, marker, ...)  
  
## S3 method for class 'list'  
alleles(x, marker, ...)  
  
afreq(x, ...)  
  
## S3 method for class 'marker'  
afreq(x, ...)  
  
## S3 method for class 'ped'  
afreq(x, marker, ...)  
  
## S3 method for class 'list'  
afreq(x, marker, ...)  
  
name(x, ...)  
  
## S3 method for class 'marker'  
name(x, ...)  
  
## S3 method for class 'ped'  
name(x, markers = NULL, ...)  
  
## S3 method for class 'list'  
name(x, markers = NULL, ...)  
  
chrom(x, ...)  
  
## S3 method for class 'marker'  
chrom(x, ...)  
  
## S3 method for class 'ped'  
chrom(x, markers = NULL, ...)  
  
## S3 method for class 'list'  
chrom(x, markers = NULL, ...)  
  
posMb(x, ...)  
  
## S3 method for class 'marker'  
posMb(x, ...)  
  
## S3 method for class 'ped'  
posMb(x, markers = NULL, ...)
```

Arguments

x Either a marker object, a ped object or a list of ped objects.

... Further arguments, not used.
 id The ID label of a single pedigree member.
 marker, markers The index or name of a marker (or a vector indicating several markers) attached to x.

Value

The associated marker attributes.

See Also

Setting marker attributes: [marker_setattr](#) and [marker_inplace](#).

Examples

```
x = nuclearPed(1)
x = addMarker(x) # add empty marker

# Inspect default attributes
alleles(x, marker = 1)
afreq(x, marker = 1)
name(x, marker = 1) # NA
chrom(x, marker = 1) # NA
```

marker_inplace	<i>Set marker attributes</i>
----------------	------------------------------

Description

These S3 methods perform in-place modifications of marker attributes. They work on single marker objects and markers attached to ped objects (or lists of such). Although these functions will continue to exist, we recommend the newer alternatives [setGenotype\(\)](#), [setAfreq\(\)](#), ... in most cases.

Usage

```
genotype(x, ...) <- value

## S3 replacement method for class 'marker'
genotype(x, id, ...) <- value

## S3 replacement method for class 'ped'
genotype(x, marker, id, ...) <- value

mutmod(x, ...) <- value

## S3 replacement method for class 'marker'
```

```
mutmod(x, ...) <- value

## S3 replacement method for class 'ped'
mutmod(x, marker = NULL, ...) <- value

## S3 replacement method for class 'list'
mutmod(x, marker = NULL, ...) <- value

afreq(x, ...) <- value

## S3 replacement method for class 'marker'
afreq(x, ...) <- value

## S3 replacement method for class 'ped'
afreq(x, marker, ...) <- value

## S3 replacement method for class 'list'
afreq(x, marker, ...) <- value

name(x, ...) <- value

## S3 replacement method for class 'marker'
name(x, ...) <- value

## S3 replacement method for class 'ped'
name(x, markers = NULL, ...) <- value

## S3 replacement method for class 'list'
name(x, markers = NULL, ...) <- value

chrom(x, ...) <- value

## S3 replacement method for class 'marker'
chrom(x, ...) <- value

## S3 replacement method for class 'ped'
chrom(x, markers = NULL, ...) <- value

## S3 replacement method for class 'list'
chrom(x, markers = NULL, ...) <- value

posMb(x, ...) <- value

## S3 replacement method for class 'marker'
posMb(x, ...) <- value

## S3 replacement method for class 'ped'
posMb(x, markers = NULL, ...) <- value
```

Arguments

x	Either a marker object, a ped object or a list of ped objects.
...	Further arguments, not used.
value	Replacement value(s).
id	The ID label of a single pedigree member.
marker, markers	The index or name of a marker (or a vector indicating several markers) attached to ped. Used if x is a ped object.

Value

These functions perform in-place modification of x.

See Also

Alternative setters (not in-place): [marker_setattr](#). Marker attribute getters: [marker_getattr](#).

Examples

```
x = nuclearPed(1)
x = addMarker(x, alleles = 1:2)

# Set genotypes
genotype(x, marker = 1, id = 1) = "1/2"

# Set marker name
name(x, 1) = "M"

# Change allele freqs
afreq(x, "M") = c(`1` = 0.1, `2` = 0.9)

# Set position
chrom(x, "M") = 1
posMb(x, "M") = 123.45

# Check result
m = marker(x, `1` = "1/2", name = "M", afreq = c(`1` = 0.1, `2` = 0.9),
           chrom = 1, posMb = 123.45)
stopifnot(identical(x$MARKERS[[1]], m))
```

marker_prop

Marker properties

Description

These functions are used to retrieve various properties of marker objects. Each function accepts as input either a single marker object, a ped object, or a list of ped objects.

Usage

```
emptyMarker(x, ...)  
  
## Default S3 method:  
emptyMarker(x, ...)  
  
## S3 method for class 'marker'  
emptyMarker(x, ...)  
  
## S3 method for class 'ped'  
emptyMarker(x, markers = NULL, ...)  
  
## S3 method for class 'list'  
emptyMarker(x, markers = NULL, ...)  
  
nTyped(x, ...)  
  
## Default S3 method:  
nTyped(x, ...)  
  
## S3 method for class 'marker'  
nTyped(x, ...)  
  
## S3 method for class 'ped'  
nTyped(x, markers = NULL, ...)  
  
## S3 method for class 'list'  
nTyped(x, markers = NULL, ...)  
  
nAlleles(x, ...)  
  
## Default S3 method:  
nAlleles(x, ...)  
  
## S3 method for class 'marker'  
nAlleles(x, ...)  
  
## S3 method for class 'ped'  
nAlleles(x, markers = NULL, ...)  
  
## S3 method for class 'list'  
nAlleles(x, markers = NULL, ...)  
  
isXmarker(x, ...)  
  
## Default S3 method:  
isXmarker(x, ...)
```

```

## S3 method for class 'marker'
isXmarker(x, ...)

## S3 method for class 'ped'
isXmarker(x, markers = NULL, ...)

## S3 method for class 'list'
isXmarker(x, markers = NULL, ...)

allowsMutations(x, ...)

## Default S3 method:
allowsMutations(x, ...)

## S3 method for class 'marker'
allowsMutations(x, ...)

## S3 method for class 'ped'
allowsMutations(x, markers = NULL, ...)

## S3 method for class 'list'
allowsMutations(x, markers = NULL, ...)

```

Arguments

x	A single marker object or a ped object (or a list of such)
...	Not used.
markers	A vector of names or indices of markers attached to x. By default all attached markers are selected.

Details

emptyMarker() returns TRUE for markers with no genotypes. If the input is a list of pedigrees, all must be empty for the result to be TRUE.

nTyped() returns the number of typed individuals for each marker. Note that if the input is a list of pedigrees, the function returns the sum over all components.

nAlleles() returns the number of alleles of each marker.

isXmarker() returns TRUE for markers whose chrom attribute is either "X" or 23.

allowsMutations returns TRUE for markers whose mutmod attribute is non-NULL and differs from the identity matrix.

Value

If x is a single marker object, the output is a vector of length 1.

Otherwise, a vector of length nMarkers(x) (default) or length(markers), reporting the property of each marker.

Examples

```

cmp1 = nuclearPed(1)
cmp2 = singleton(10)
loc = list(alleles = 1:2)
x = setMarkers(list(cmp1, cmp2), locus = rep(list(loc), 3))

#----- nAlleles() -----
# All markers have 2 alleles
stopifnot(identical(nAlleles(x), c(2L,2L,2L)))

#----- emptyMarkers() -----
# Add genotype for indiv 1 at marker 1
genotype(x[[1]], 1, 1) = "1/2"

# Check that markers 2 and 3 are empty
stopifnot(identical(emptyMarker(x), c(FALSE,TRUE,TRUE)),
          identical(emptyMarker(x[[1]]), c(FALSE,TRUE,TRUE)),
          identical(emptyMarker(x[[2]]), c(TRUE,TRUE,TRUE)),
          identical(emptyMarker(x, markers = c(3,1)), c(TRUE,FALSE)))

#----- nTyped() -----
stopifnot(identical(nTyped(x), c(1L,0L,0L)))

# Add genotypes for third marker
genotype(x[[1]], marker = 3, id = 1:3) = "1/1"
genotype(x[[2]], marker = 3, id = 10) = "2/2"

# nTyped() returns total over all components
stopifnot(identical(nTyped(x), c(1L,0L,4L)))

#----- allowsMutations() -----
# Marker 2 allows mutations
mutmod(x, 2) = list("prop", rate = 0.1)

stopifnot(identical(allowsMutations(x), c(FALSE,TRUE,FALSE)),
          identical(allowsMutations(x, markers = 2:3), c(TRUE,FALSE)))

#----- isXmarker() -----
# Make marker 3 X-linked
chrom(x[[1]], 3) = "X"
chrom(x[[2]], 3) = "X"

stopifnot(identical(isXmarker(x), c(FALSE,FALSE,TRUE)))

```

marker_select

Select or remove attached markers

Description

Functions for manipulating markers attached to ped objects.

Usage

```
selectMarkers(x, markers = NULL, chroms = NULL, fromPos = NULL, toPos = NULL)
```

```
getMarkers(x, markers = NULL, chroms = NULL, fromPos = NULL, toPos = NULL)
```

```
removeMarkers(x, markers = NULL, chroms = NULL, fromPos = NULL, toPos = NULL)
```

```
whichMarkers(x, markers = NULL, chroms = NULL, fromPos = NULL, toPos = NULL)
```

Arguments

x	A ped object, or a list of such
markers	Either a character vector (with marker names), a numeric vector (with marker indices), a logical (of length <code>nMarkers(x)</code>), or <code>NULL</code> .
chroms	A vector of chromosome names, or <code>NULL</code>
fromPos	A single number or <code>NULL</code>
toPos	A single number or <code>NULL</code>

Details

If `markers` consists of negative integers, it will be converted to its complement within `1 : nMarkers(x)`.

Value

The return values of these functions are:

- `selectMarkers()`: an object identical to `x`, but where only the indicated markers are kept
- `removeMarkers()`: an object identical to `x`, but where the indicated markers are removed
- `getMarkers()`: a list of marker objects. Note: If `x` is a list of pedigrees, the marker objects attached to the first component will be returned.
- `whichMarkers()`: an integer vector with indices of the indicated markers. If `x` is a list of pedigrees an error is raised unless `whichMarkers()` gives the same result for all components.

See Also

[setMarkers\(\)](#)

marker_setattr *Set marker attributes*

Description

These functions set or modify various attributes of markers attached to a pedigree. They are sometimes more convenient (and pipe-friendly) than the in-place modifiers described in [marker_inplace](#).

Usage

```
setGenotype(x, marker = NULL, id, geno)
setAfreq(x, marker, afreq, strict = TRUE)
setMarkername(x, marker = NULL, name)
setChrom(x, marker = NULL, chrom)
setPosition(x, marker = NULL, posMb)
```

Arguments

x	A ped object or a list of ped objects.
marker	A vector of indices or names of one or several markers attached to x.
id	The ID label of a single pedigree member.
geno	A character vector of length pedsizes(x), with genotypes written in the format "a/b".
afreq	A numeric of the same length as alleles, indicating the population frequency of each allele. A warning is issued if the frequencies don't sum to 1 after rounding to 3 decimals. If the vector is named, and alleles is not NULL, an error is raised if setequal(names(afreq), alleles) is not TRUE. If afreq is not specified, all alleles are given equal frequencies.
strict	A logical. If TRUE (default) the new frequencies cannot remove or add any alleles.
name	A character of the same length as marker, containing marker names.
chrom	A character of the same length as marker, containing chromosome labels.
posMb	A numeric of the same length as marker, containing the physical marker positions in megabases (or NA).

Value

A copy of x with modified attributes.

Examples

```
x = nuclearPed(1) |>
  addMarker(alleles = 1:2) |>
  setMarkername(marker = 1, name = "M") |>
  setGenotype(marker = "M", id = 1, geno = "1/2") |>
  setAfreq(marker = "M", afreq = c(`1` = 0.1, `2` = 0.9)) |>
  setChrom(marker = "M", chrom = 1) |>
  setPosition(marker = "M", posMb = 123.45)

# Of course, all of this could have been done on creation:
y = addMarker(nuclearPed(), `1` = "1/2", afreq = c(`1` = 0.1, `2` = 0.9),
             name = "M", chrom = 1, posMb = 123.45)
stopifnot(identical(x, y))
```

mendelianCheck	<i>Check for Mendelian errors</i>
----------------	-----------------------------------

Description

Check marker data for Mendelian inconsistencies

Usage

```
mendelianCheck(x, remove = FALSE, verbose = !remove)
```

Arguments

x	a <code>ped()</code> object
remove	a logical. If FALSE, the function returns the indices of markers found to incorrect. If TRUE, a new ped object is returned, where the incorrect markers have been deleted.
verbose	a logical. If TRUE, details of the markers failing the tests are shown.

Value

A numeric containing the indices of the markers that did not pass all tests, or (if `remove = TRUE`) a new ped object where the failing markers are removed.

Author(s)

Magnus Dehli Vigeland

Examples

```
x = nuclearPed()

# Add a SNP with Mendelian error
m = marker(x, '1' = "1/1", '2' = "1/1", '3' = "1/2")
x = setMarkers(x, m)

mendelianCheck(x)
```

mergePed

*Merge two pedigrees***Description**

This function merges two ped objects, joining them at the indicated individuals. Only ped objects without marker data are supported.

Usage

```
mergePed(x, y, by = NULL, relabel = FALSE, ...)
```

Arguments

x, y	ped() objects
by	The individuals to merge by. The most general form uses a named vector with entries of the form <code>id.x = id.y</code> (see Examples). If the vector is unnamed, it is assumed that the merging individuals have the same labels in both pedigrees. Finally, if <code>by = NULL</code> (default), it is set to <code>intersect(labels(x), labels(y))</code> .
relabel	A logical, by default FALSE. If TRUE, <code>relabel(..., "asPlot")</code> is run on the merged pedigree before returning.
...	further arguments passed along to <code>ped()</code> , e.g. <code>famid</code> , <code>validate</code> and <code>reorder</code> .

Details

Some internal checks are done to ensure that merging individuals have the same sex and the same parents.

If `relabel = FALSE`, some relabelling might still be performed in order to ensure unique labels for everyone. Specifically, this is the case if some ID labels occur in both `x` and `y` other than those given in the `by` argument. In such cases, the relevant members of `y` get a suffix `.y`.

Value

A ped object.

Author(s)

Magnus Dehli Vigeland

Examples

```
#####
# Example 1
# A family trio where each parent have first cousin parents.
#####

# Trio
x = nuclearPed(1)

# Add paternal family
pat = cousinPed(1, child = TRUE)
x = mergePed(x, pat, by = c("1" = "9"))

# Maternal family
mat = cousinPed(1, child = TRUE) |> swapSex("9")
x = mergePed(x, mat, by = c("2" = "9"))

# Relabel (Alternative: add `relabel = TRUE` in the previous call)
x = relabel(x, "asPlot")

plot(x)

#####
# Example 2: Double first cousins
#####

# First cousins, whose fathers are brothers
y = cousinPed(degree = 1)

# Create two sisters
motherPed = nuclearPed(2, sex = 2)

# Plot to see who is who: `plotPedList(list(y, motherPed))`

# Merge
z = mergePed(y, motherPed, by = c("4" = 3, "6" = 4), relabel = TRUE)
plot(z)
```

Description

This is the internal constructor of marker objects. It does not do any input validation and should only be used in programming scenarios, and only if you know what you are doing. Most users are recommended to use the regular constructor `marker()`.

Usage

```
newMarker(
  alleleMatrixInt,
  alleles,
  afreq,
  name = NA_character_,
  chrom = NA_character_,
  posMb = NA_real_,
  mutmod = NULL,
  pedmembers,
  sex
)
```

Arguments

<code>alleleMatrixInt</code>	An integer matrix.
<code>alleles</code>	A character vector.
<code>afreq</code>	A numeric vector.
<code>name</code>	A character of length 1.
<code>chrom</code>	A character of length 1.
<code>posMb</code>	A numeric of length 1.
<code>mutmod</code>	A mutation model.
<code>pedmembers</code>	A character vector.
<code>sex</code>	An integer vector.

Details

See `marker()` for more details about the marker attributes.

Value

A marker object.

Examples

```
newMarker(matrix(c(1L, 0L, 1L, 1L, 0L, 2L), ncol = 2),
  alleles = c("A", "B"), afreq = c(0.1, 0.9), name = "M",
  pedmembers = c("1", "2", "3"), sex = c(1L, 2L, 1L))
```

newPed	<i>Internal ped constructor</i>
--------	---------------------------------

Description

This is the internal constructor of ped objects. It does not do any validation of input other than simple type checking. In particular it should only be used in programming scenarios where it is known that the input is a valid, connected pedigree. End users are recommended to use the regular constructor [ped\(\)](#).

Usage

```
newPed(ID, FIDX, MIDX, SEX, FAMID, detectLoops = TRUE)
```

Arguments

ID	A character vector.
FIDX	An integer vector.
MIDX	An integer vector.
SEX	An integer vector.
FAMID	A string.
detectLoops	A logical.

Details

See [ped\(\)](#) for details about the input parameters.

Value

A ped object.

Examples

```
newPed("a", 0L, 0L, 1L, "")
```

nMarkers	<i>The number of markers attached to a pedigree</i>
----------	---

Description

The number of markers attached to a pedigree

Usage

```
nMarkers(x)
```

```
hasMarkers(x)
```

Arguments

x A ped object or a list of such (see Value).

Value

The function nMarkers returns the number of marker objects attached to x. If x is a list of pedigrees, an error is raised unless all of them have the same number of markers.

The function hasMarkers returns TRUE if nMarkers(x) > 0.

ped	<i>Pedigree construction</i>
-----	------------------------------

Description

This is the basic constructor of ped objects. Utility functions for creating many common pedigree structures are described in [ped_basic](#).

Usage

```
ped(
  id,
  fid,
  mid,
  sex,
  famid = "",
  reorder = TRUE,
  validate = TRUE,
  detectLoops = TRUE,
  isConnected = FALSE,
  verbose = FALSE
)

singleton(id = 1, sex = 1, famid = "")
```

Arguments

<code>id</code>	A vector (numeric or character) of individual ID labels.
<code>fid</code>	A vector of the same length as <code>id</code> , containing the labels of the fathers. In other words <code>fid[i]</code> is the father of <code>id[i]</code> , or 0 if <code>id[i]</code> is a founder.
<code>mid</code>	A vector of the same length as <code>id</code> , containing the labels of the mothers. In other words <code>mid[i]</code> is the mother of <code>id[i]</code> , or 0 if <code>id[i]</code> is a founder.
<code>sex</code>	A numeric of the same length as <code>id</code> , describing the genders of the individuals (in the same order as <code>id</code> .) Each entry must be either 1 (=male), 2 (=female) or 0 (=unknown).
<code>famid</code>	A character string. Default: An empty string.
<code>reorder</code>	A logical indicating if the pedigree should be reordered so that all parents precede their children. Default: TRUE.
<code>validate</code>	A logical indicating if a validation of the pedigree structure should be performed. Default: TRUE.
<code>detectLoops</code>	A logical indicating if the presence of loops should be detected. Setting this to FALSE may speed up the processing of large pedigrees. Default: TRUE.
<code>isConnected</code>	A logical indicating if the input is known to be a connected pedigree. Setting this to TRUE speeds up the processing. Default: FALSE.
<code>verbose</code>	A logical.

Details

A singleton is a special ped object whose pedigree contains 1 individual. The class attribute of a singleton is `c('singleton', 'ped')`.

Selfing, i.e. the presence of pedigree members whose father and mother are the same individual, is allowed in ped objects. Any such "self-fertilizing" parent must have undecided sex (`sex = 0`).

If the pedigree is disconnected, it is split into its connected components and returned as a list of ped objects.

Value

A ped object, which is essentially a list with the following entries:

- `ID` : A character vector of ID labels. Unless the pedigree is reordered during creation, this equals `as.character(id)`
- `FIDX` : An integer vector with paternal indices: For each $j = 1, 2, \dots$, the entry `FIDX[j]` is 0 if `ID[j]` has no father within the pedigree; otherwise `ID[FIDX[j]]` is the father of `ID[j]`.
- `MIDX` : An integer vector with maternal indices: For each $j = 1, 2, \dots$, the entry `MIDX[j]` is 0 if `ID[j]` has no mother within the pedigree; otherwise `ID[MIDX[j]]` is the mother of `ID[j]`.
- `SEX` : An integer vector with gender codes. Unless the pedigree is reordered, this equals `as.integer(sex)`.
- `FAMID` : The family ID.
- `UNBROKEN_LOOPS` : A logical indicating if the pedigree has unbroken loops, or NA if the status is currently unknown.

- LOOP_BREAKERS : A matrix with loop breaker ID's in the first column and their duplicates in the second column. All entries refer to the internal IDs. This is usually set by `breakLoops()`.
- FOUNDER_INBREEDING : A list of two potential entries, "autosomal" and "x"; both numeric vectors with the same length as `founders(x)`. FOUNDER_INBREEDING is always NULL when a new ped is created. See `founderInbreeding()`.
- MARKERS : A list of marker objects, or NULL.

Examples

```
# Trio
x = ped(id = 1:3, fid = c(0,0,1), mid = c(0,0,2), sex = c(1,2,1))

# Female singleton
y = singleton('NN', sex = 2)

# Selfing
z = ped(id = 1:2, fid = 0:1, mid = 0:1, sex = 0:1)
stopifnot(hasSelfing(z))

# Disconnected pedigree: Trio + singleton
w = ped(id = 1:4, fid = c(2,0,0,0), mid = c(3,0,0,0), sex = c(1,1,2,1))
stopifnot(is.pedList(w), length(w) == 2)
```

ped_basic

Create simple pedigrees

Description

Utility functions for creating some common pedigree structures.

Usage

```
nuclearPed(nch = 1, sex = 1, father = "1", mother = "2", children = NULL)
```

```
halfSibPed(
  nch1 = 1,
  nch2 = 1,
  sex1 = 1,
  sex2 = 1,
```

```

    type = c("paternal", "maternal")
  )

linearPed(n, sex = 1)

cousinPed(
  degree,
  removal = 0,
  side = c("right", "left"),
  half = FALSE,
  child = FALSE
)

avuncularPed(
  top = c("uncle", "aunt"),
  bottom = c("nephew", "niece"),
  side = c("right", "left"),
  type = c("paternal", "maternal"),
  removal = 1,
  half = FALSE
)

halfCousinPed(degree, removal = 0, side = c("right", "left"), child = FALSE)

ancestralPed(g)

selfingPed(s, sex = 1)

```

Arguments

nch	The number of children, by default 1. If children is not NULL, nch is set to length(children)
sex	A vector with integer gender codes (0=unknown, 1=male, 2=female). In nuclearPed(), it contains the genders of the children and is recycled (if necessary) to length nch. In linearPed() it also contains the genders of the children (1 in each generation) and should have length at most n (recycled if shorter than this). In selfingPed() it should be a single number, indicating the gender of the last individual (the others must necessarily have gender code 0.)
father	The label of the father. Default: "1".
mother	The label of the mother. Default: "2".
children	A character with labels of the children. Default: "3", "4", ...
nch1, nch2	The number of children in each sibship.
sex1, sex2	Vectors of gender codes for the children in each sibship. Recycled (if necessary) to lengths nch1 and nch2 respectively.
type	Either "paternal" or "maternal".
n	The number of generations, not including the initial founders.

degree	A non-negative integer: 0=siblings, 1=first cousins; 2=second cousins, a.s.o.
removal	A non-negative integer. See Details and Examples.
side	Either "right" or "left"; the side on which removals should be added.
half	A logical indicating if the relationship should be "half-like". Default: FALSE.
child	A logical: Should an inbred child be added to the two bottom individuals?
top, bottom	Words indicating the gender combination in avuncular relationships. The first must be either "uncle" or "aunt", while the second is "nephew" or "niece". Both can be abbreviated.
g	A nonnegative integer indicating the number of ancestral generations to include. The resulting pedigree has $2^{(g+1)}-1$ members. The case $g = 0$ results in a singleton.
s	A nonnegative integer indicating the number of consecutive selfings. The case $s = 0$ results in a singleton.

Details

halfSibPed(nch1, nch2) produces a pedigree containing two sibships (of sizes nch1 and nch2) with the same father, but different mothers. If maternal half sibs are wanted instead, add type = "maternal".

cousinPed(degree = n, removal = k) creates a pedigree with two n`th cousins, k times removed. By default, removals are added on the right side, but this can be changed by adding side = left.

halfCousinPed(...) is a synonym for cousinPed(..., half = TRUE).

avuncularPed() creates uncle/aunt - nephew/niece pedigrees. The empty call avuncularPed() is equivalent to avuncularPed("uncle", "nephew"). Note that the arguments can be abbreviated, so that e.g. avuncularPed("a", "ni") produces an aunt-niece relationship. Grand (and great-grand etc) uncles/aunts can be produced by specifying removal greater than 1.

ancestralPed(g) returns the family tree of a single individual, including all ancestors g generations back.

selfingPed(s) returns a line of s consecutive selfings.

Value

A ped object.

See Also

[ped\(\)](#), [singleton\(\)](#), [ped_complex](#), [ped_subgroups](#)

Examples

```
# A nuclear family with 2 boys and 3 girls
nuclearPed(5, sex = c(1, 1, 2, 2, 2))
```

```
# A straight line of females
linearPed(3, sex = 2)
```

```

# Paternal half brothers
halfSibPed()

# Maternal half sisters
halfSibPed(sex1 = 2, sex2 = 2, type = "maternal")

# Larger half sibships: boy and girl on one side; 3 girls on the other
halfSibPed(nch1 = 2, sex = 1:2, nch2 = 3, sex2 = 2)

# Grand aunt:
cousinPed(degree = 0, removal = 2)

# Second cousins once removed.
cousinPed(degree = 2, removal = 1)

# Same, but with the 'removal' on the left side.
cousinPed(2, 1, side = "left")

# A child of half first cousins.
halfCousinPed(degree = 1, child = TRUE)

# The 'family tree' of a person
ancestralPed(g = 2)

```

ped_complex

Complex pedigree structures

Description

Functions for creating a selection of pedigrees that are awkward to construct from scratch or with the simple structures described in [ped_basic](#).

Usage

```

doubleCousins(
  degree1,
  degree2,
  removal1 = 0,
  removal2 = 0,
  half1 = FALSE,
  half2 = FALSE,
  child = FALSE
)

doubleFirstCousins()

quadHalfFirstCousins()

```

```
fullSibMating(n)
```

```
halfSibStack(n)
```

```
halfSibTriangle(g)
```

Arguments

```
degree1, degree2, removal1, removal2
```

Nonnegative integers.

```
half1, half2
```

Logicals, indicating if the fathers (resp. mothers) should be full or half cousins.

```
child
```

A logical: Should a child be added to the double cousins?

```
n
```

A positive integer indicating the number of crossings.

```
g
```

A positive integer; the number of generations.

Details

The function `doubleCousins` returns a pedigree linking two individuals who are simultaneous paternal and maternal cousins. More precisely, they are:

- paternal (full or half) cousins of type `(degree1, removal1)`
- maternal (full or half) cousins of type `(degree2, removal2)`.

For convenience, a wrapper `doubleFirstCousins` is provided for the most common case, double first cousins.

`quadHalfFirstCousins` produces a pedigree with quadruple half first cousins.

`fullSibMating` crosses full sibs consecutively `n` times.

`halfSibStack` produces a breeding scheme where the two individuals in the final generation are simultaneous half k 'th cousins, for each $k = 0, \dots, n-1$.

`halfSibTriangle` produces a triangular pedigree in which every pair of parents are half siblings.

Value

A [ped](#) object.

See Also

[ped_basic](#)

Examples

```
# Consecutive brother-sister matings.
x = fullSibMating(2)
# plot(x)

# Simultaneous half siblings and half first cousins
```

```

x = halfSibStack(2)
# plot(x)

# Double first cousins
x = doubleFirstCousins()
# plot(x)

# Quadruple half first cousins
x = quadHalfFirstCousins()
# plot(x) # Weird plotting behaviour for this pedigree.

# Triangular half-sib pattern
x = halfSibTriangle(4)
# plot(x)

```

ped_internal

Internal ordering of pedigree members

Description

These functions give access to - and enable modifications of - the order in which the members of a pedigree are stored. (This is the order in which the members are listed when a ped object is printed to the screen.)

Usage

```

reorderPed(x, neworder = NULL)

parentsBeforeChildren(x)

hasParentsBeforeChildren(x)

foundersFirst(x)

internalID(x, ids, errorIfUnknown = TRUE)

```

Arguments

x	A ped object. Most of these functions also accepts ped lists.
neworder	A permutation of labels(x) or of vector 1 : pedsizes(x). By default, the sorting order of the ID labels is used.
ids	A character vector (or coercible to one) of original ID labels.
errorIfUnknown	A logical. If TRUE (default), the function stops with an error if not all elements of ids are recognised as names of members in x.

Details

The internal ordering is usually of little importance for end users, with one important exception: Certain pedigree-traversing algorithms require parents to precede their children. A special function, `parentsBeforeChildren()` is provided for this purpose. This is a wrapper of the more general `reorderPed()` which allows any permutation of the members.

It should be noted that `ped()` by default calls `parentsBeforeChildren()` whenever a pedigree is created, unless explicitly avoided with `reorder = FALSE`.

`hasParentsBeforeChildren()` can be used as a quick test to decide if it is necessary to call `parentsBeforeChildren()`.

The `foundersFirst()` function reorders the pedigree so that all the founders come first.

The utility `internalID()` converts ID labels to indices in the internal ordering. If `x` is a list of pedigrees, the output is a data frame containing both the component number and internal ID (within the component).

See Also

[ped\(\)](#)

Examples

```
x = ped(id = 3:1, fid = c(1,0,0), mid = c(2,0,0), sex = c(1,2,1), reorder = FALSE)
x

# The 'ids' argument is converted to character, hence these are equivalent:
internalID(x, ids = 3)
internalID(x, ids = "3")

hasParentsBeforeChildren(x)

# Fix the ordering
y = parentsBeforeChildren(x)
internalID(y, ids = 3)

# A different ordering
reorderPed(x, c(2,1,3))
```

ped_modify

Add/remove pedigree members

Description

Functions for adding or removing individuals in a 'ped' object.

Usage

```

addChildren(
  x,
  father = NULL,
  mother = NULL,
  nch = NULL,
  sex = 1,
  ids = NULL,
  verbose = TRUE
)

addSon(x, parents, id = NULL, verbose = TRUE)

addDaughter(x, parents, id = NULL, verbose = TRUE)

addParents(x, id, father = NULL, mother = NULL, verbose = TRUE)

removeIndividuals(
  x,
  ids,
  remove = c("descendants", "ancestors"),
  returnLabs = FALSE,
  verbose = TRUE
)

branch(x, id)

## S3 method for class 'ped'
subset(x, subset, ...)

```

Arguments

x	A ped object.
father, mother	Single ID labels. At least one of these must belong to an existing pedigree member. The other label may either: 1) belong to an existing member, 2) not belong to any existing member, or 3) be missing (i.e. not included in the function call). In cases 2 and 3 a new founder is added to the pedigree. In case 2 its label is the one given, while in case 3 a suitable label is created by the program (see Details).
nch	A positive integer indicating the number of children to be created. Default: 1.
sex	Gender codes of the created children (recycled if needed).
ids	A character vector (or coercible to such) with ID labels. In addChildren the (optional) ids argument is used to specify labels for the created children. If given, its length must equal nch. If not given, labels are assigned automatically as explained in Details.
verbose	A logical: Verbose output or not.

parents	A vector of 1 or 2 ID labels, of which at least one must be an existing member of x.
id	The ID label of a pedigree member.
remove	Either "ancestors" or "descendants" (default), dictating the method of removing pedigree members. Abbreviations are allowed.
returnLabs	A logical, by default FALSE. If TRUE, removeIndividuals() returns only the labels of all members to be removed, instead of actually removing them.
subset	A character vector (or coercible to such) with ID labels forming a connected sub-pedigree.
...	Not used.

Details

In `addChildren()` and `addParents()`, labels of added individuals are created automatically if they are not specified by the user. In the automatic case, the labelling depends on whether the existing labels are integer-like or not (i.e. if `labels(x)` equals `as.character(as.integer(labels(x)))`.) If so, the new labels are integers subsequent to the largest of the existing labels. If not, the new labels are "NN_1", "NN_2", ... If any such label already exists, the numbers are adjusted accordingly.

`addSon()` and `addDaughter()` are wrappers for the most common use of `addChildren()`, namely adding a single child to a pedigree. Note that the parents can be given in any order. If only one parent is supplied, the other is created as a new individual.

`removeIndividuals()` removes the individuals indicated with `ids` along with all of their ancestors OR descendants, depending on the `remove` argument. Leftover spouses disconnected to the remaining pedigree are also removed. An error is raised if result is a disconnected pedigree.

The `branch()` function extracts the sub-pedigree formed by `id` and all his/her spouses and descendants.

Finally, `subset()` can be used to extract any connected sub-pedigree. (Note that in the current implementation, the function does not actually check that the indicated subset forms a connected pedigree; failing to comply with this may lead to obscure errors.)

Value

The modified ped object.

[ped\(\)](#), [relabel\(\)](#), [swapSex\(\)](#)

Examples

```
x = nuclearPed(1) |>
  addSon(3) |>
  addParents(4, father = 6, mother = 7) |>
  addChildren(father = 6, mother = 7, nch = 3, sex = c(2,1,2))

# Remove 6 and 7 and their descendants
```

```
y1 = removeIndividuals(x, 6:7)

# Remove 8-10 and their parents
y2 = removeIndividuals(x, 8:10, remove = "ancestors")
```

ped_subgroups

Pedigree subgroups

Description

A collection of utility functions for identifying pedigree members with certain properties.

Usage

```
founders(x, internal = FALSE)
nonfounders(x, internal = FALSE)
leaves(x, internal = FALSE)
males(x, internal = FALSE)
females(x, internal = FALSE)
typedMembers(x, internal = FALSE)
untypedMembers(x, internal = FALSE)
father(x, id, internal = FALSE)
mother(x, id, internal = FALSE)
children(x, id, internal = FALSE)
offspring(x, id, internal = FALSE)
spouses(x, id, internal = FALSE)
unrelated(x, id, internal = FALSE)
parents(x, id, internal = FALSE)
grandparents(x, id, degree = 2, internal = FALSE)
siblings(x, id, half = NA, internal = FALSE)
```

```
nephews_nieces(x, id, removal = 1, half = NA, internal = FALSE)
```

```
ancestors(x, id, inclusive = FALSE, internal = FALSE)
```

```
commonAncestors(x, ids, inclusive = FALSE, internal = FALSE)
```

```
descendants(x, id, inclusive = FALSE, internal = FALSE)
```

```
commonDescendants(x, ids, inclusive = FALSE, internal = FALSE)
```

```
descentPaths(x, ids = founders(x), internal = FALSE)
```

Arguments

<code>x</code>	A <code>ped()</code> object or a list of such.
<code>internal</code>	A logical indicating whether <code>id</code> (or <code>ids</code>) refers to the internal order.
<code>id, ids</code>	A character (or coercible to such) with one or several ID labels.
<code>degree, removal</code>	Non-negative integers.
<code>half</code>	a logical or NA. If TRUE (resp. FALSE), only half (resp. full) siblings/cousins/nephews/nieces are returned. If NA, both categories are included.
<code>inclusive</code>	A logical indicating whether an individual should be counted among his or her own ancestors/descendants

Value

The functions `founders`, `nonfounders`, `males`, `females`, `leaves` each return a vector containing the IDs of all pedigree members with the wanted property. (Recall that a founder is a member without parents in the pedigree, and that a leaf is a member without children in the pedigree.)

The functions `father`, `mother`, `cousins`, `grandparents`, `nephews_nieces`, `children`, `parents`, `siblings`, `spouses`, `unrelated`, each returns a vector containing the IDs of all pedigree members having the specified relationship with `id`.

The commands `ancestors(x, id)` and `descendants(x, id)` return vectors containing the IDs of all ancestors (resp. descendants) of the individual `id` within the pedigree `x`. If `inclusive = TRUE`, `id` is included in the output, otherwise not.

For `commonAncestors(x, ids)` and `commonDescendants(x, ids)`, the output is a vector containing the IDs of common ancestors (descendants) to all of `ids`.

Finally, `descentPaths(x, ids)` returns a list of lists, containing all pedigree paths descending from each individual in `ids` (by default all founders).

Author(s)

Magnus Dehli Vigeland

Examples

```

x = ped(id = 2:9,
        fid = c(0,0,2,0,4,4,0,2),
        mid = c(0,0,3,0,5,5,0,8),
        sex = c(1,2,1,2,1,2,2,2))

spouses(x, id = 2) # 3, 8
children(x, 2)    # 4, 9
descendants(x, 2)  # 4, 6, 7, 9
siblings(x, 4)   # 9 (full or half)
unrelated(x, 4)  # 5, 8
father(x, 4)     # 2
mother(x, 4)     # 3

siblings(x, 4, half = FALSE) # none
siblings(x, 4, half = TRUE)  # 9

leaves(x)        # 6, 7, 9
founders(x)      # 2, 3, 5, 8

```

ped_utils

Pedigree utilities

Description

Various utility functions for ped objects.

Usage

```

pedsize(x)

generations(
  x,
  what = c("max", "compMax", "indiv", "depth"),
  maxOnly = TRUE,
  maxComp = TRUE
)

hasUnbrokenLoops(x)

hasInbredFounders(x, chromType = "autosomal")

hasSelfing(x)

hasCommonAncestor(x)

```

subnucs(x)

peelingOrder(x)

Arguments

x	A ped object, or (in some functions - see Details) a list of such.
what	Either "max", "compMax", "indiv" or "depth" (See Value.)
maxOnly, maxComp	Deprecated; use 'what' instead.
chromType	Either "autosomal" (default) or "x".

Value

- `pedsize(x)` returns the number of pedigree members in each component of `x`.
- `generations(x)` by default returns the number of generations in `x`, defined as the number of individuals in the longest line of parent-child links. (Note that this is well-defined also if `x` has loops and/or cross-generational marriages.) For individual generation numbers, use `what = "indiv"` (generation numbering as in the plot) or `what = "depth"` (length of the longest chain up to a founder); the function returns a vector with the generation count from each component.
- `hasUnbrokenLoops(x)` returns TRUE if `x` has loops, otherwise FALSE. (No computation is done here; the function simply returns the value of `x$UNBROKEN_LOOPS`).
- `hasInbredFounders(x)` returns TRUE if founder inbreeding is specified for `x` and at least one founder has positive inbreeding coefficient. See [founderInbreeding\(\)](#) for details.
- `hasSelfing(x)` returns TRUE if the pedigree contains selfing events. This is recognised by father and mother begin equal for some child. (Note that for this to be allowed, the gender code of the parent must be 0.)
- `hasCommonAncestor(x)` computes a logical matrix `A` whose entry `A[i, j]` is TRUE if pedigree members `i` and `j` have a common ancestor in `x`, and FALSE otherwise. By convention, `A[i, i]` is TRUE for all `i`.
- `subnucs(x)` returns a list of all nuclear sub-pedigrees of `x`, wrapped as `nucleus` objects. Each nucleus is a list with entries `father`, `mother` and `children`.
- `peelingOrder(x)` calls `subnucs(x)` and extends each entry with a `link` individual, indicating a member linking the nucleus to the remaining pedigree. One application of this function is the fact that it *fails* to find a complete peeling order if and only if the pedigree has loops. (In fact it is called each time a new ped object is created by `ped()` in order to detect loops.) The main purpose of the function, however, is to prepare for probability calculations in other packages, as e.g. in `pedprobr::likelihood`.

Examples

```
x = fullSibMating(1)
stopifnot(pedsize(x) == 6)
stopifnot(hasUnbrokenLoops(x))
stopifnot(generations(x) == 3)

# All members have common ancestors except the grandparents
```

```

CA = hasCommonAncestor(x)
stopifnot(!CA[1,2], !CA[2,1], sum(CA) == length(CA) - 2)

# Effect of breaking the loop
y = breakLoops(x)
stopifnot(!hasUnbrokenLoops(y))
stopifnot(pedsize(y) == 7)

# A pedigree with selfing (note the necessary `sex = 0`)
z1 = singleton(1, sex = 0)
z2 = addChildren(z1, father = 1, mother = 1, nch = 1)
stopifnot(!hasSelfing(z1), hasSelfing(z2))

# Nucleus sub-pedigrees
stopifnot(length(subnucls(z1)) == 0)
peelingOrder(cousinPed(1))

# Plot with generation numbers as labels
w = cousinPed(1)
g = generations(w, what = "indiv")
labs = setNames(labels(w), g)
plot(w, labs = labs)

# ... compare with
plot(relabel(w, "generations"))

```

plot.ped

Plot pedigree

Description

This is the main function for pedigree plotting, with many options for controlling the appearance of pedigree symbols and accompanying labels. The main pedigree layout is calculated with the `kinship2` package, see [kinship2::align.pedigree](#) for details. Unlike `kinship2`, the implementation here also supports singletons, and plotting pedigrees as DAGs. In addition, some minor adjustments have been made to improve scaling and avoid unneeded duplications.

Usage

```

## S3 method for class 'ped'
plot(x, draw = TRUE, keep.par = FALSE, ...)

drawPed(alignment, annotation = NULL, scaling = NULL, keep.par = FALSE, ...)

## S3 method for class 'pedList'
plot(x, ...)

## S3 method for class 'list'
plot(x, ...)

```

Arguments

x	A ped() object.
draw	A logical, by default TRUE. If FALSE, no plot is produced, only the plotting parameters are returned.
keep.par	A logical, by default FALSE. If TRUE, the graphical parameters are not reset after plotting, which may be useful for adding additional annotation.
...	Arguments passed on to the internal plot functions. For a complete list of parameters, see internalplot . The most important ones are illustrated in the Examples below.
alignment	List of alignment details, as returned by .pedAlignment() .
annotation	List of annotation details as returned by .pedAnnotation() .
scaling	List of scaling parameters as returned by .pedScaling() .

Details

For an overview of all plotting options, see the separate page [internalplot](#), which documents the internal plotting procedure in more detail.

Value

A list of three lists with various plot details: alignment, annotation, scaling.

See Also

[plotPedList\(\)](#), [kinship2::plot.pedigree\(\)](#). Plot options are documented in [internalplot](#).

Examples

```
# Singleton
plot(singleton(1))

# Trio
x = nuclearPed(father = "fa", mother = "mo", child = "boy")
plot(x)

#' # Modify margins
plot(x, margins = 6)
plot(x, margins = c(0,0,6,6)) # b,l,t,r

# Larger text and symbols
plot(x, cex = 1.5)

# Enlarge symbols only
plot(x, symbolsize = 1.5)

# Other options
plot(x, hatched = "boy", starred = "fa", deceased = "mo", title = "Fam 1")
```

```
# Medical pedigree
plot(x, aff = "boy", carrier = "mo")

# Label only some members
plot(x, labs = c("fa", "mo"))

# Label males only
plot(x, labs = males)

# Rename some individuals
plot(x, labs = c(FATHER = "fa", "boy"))

# Colours
plot(x, col = c(fa = "red"), fill = c(mo = "green", boy = "blue"))

# Non-black hatch colours are specified with the `fill` argument
plot(x, hatched = labels, fill = c(boy = "red"))

# Use functions to specify colours
plot(x, fill = list(red = leaves, blue = ancestors(x, "boy")))

# Line type and width
plot(x, lty = 2, lwd = 3, cex = 2)

# Detailed line type and width
plot(x, lty = list(dashed = founders), lwd = c(boy = 4))

# Include genotypes
x = addMarker(x, fa = "1/1", boy = "1/2", name = "SNP")
plot(x, marker = 1)

# Markers can also be called by name
plot(x, marker = "SNP")

# Plot as DAG (directed acyclic graph)
plot(x, arrows = TRUE, title = "DAG")

# Founder inbreeding is shown by default
founderInbreeding(x, "mo") = 0.1
plot(x)

# ... but can be suppressed
plot(x, fouInb = NULL)

# Other text above and inside symbols
plot(x, textAbove = letters[1:3], textInside = LETTERS[1:3])

# Twins
x = nuclearPed(children = c("tw1", "tw2", "tw3"))
plot(x, twins = data.frame(id1 = "tw1", id2 = "tw2", code = 1)) # MZ
plot(x, twins = data.frame(id1 = "tw1", id2 = "tw2", code = 2)) # DZ

# Triplets
```

```

plot(x, twins = data.frame(id1 = c("tw1", "tw2"),
                           id2 = c("tw2", "tw3"),
                           code = 2))

# Selfing
plot(selfingPed(2))

# Complex pedigree: Quadruple half first cousins
plot(quadHalfFirstCousins())

# Straight legs
plot(quadHalfFirstCousins(), align = c(0,0))

# Use of `drawPed()`
dat = plot(nuclearPed(), draw = FALSE)
drawPed(dat$alignment, dat$annotation, dat$scaling)

```

plotPedList

Plot a collection of pedigrees.

Description

This function creates a row of pedigree plots, each created by `plot.ped()`. Any parameter accepted by `plot.ped()` can be applied, either to all plots simultaneously, or to individual plots. Some effort is made to guess a reasonable window size and margins, but in general the user must be prepared to do manual resizing of the plot window. See various examples in the Examples section below.

Usage

```

plotPedList(
  plots,
  widths = NULL,
  groups = NULL,
  titles = NULL,
  frames = TRUE,
  fmar = NULL,
  source = NULL,
  dev.height = NULL,
  dev.width = NULL,
  newdev = !is.null(dev.height) || !is.null(dev.width),
  verbose = FALSE,
  ...
)

```

Arguments

plots A list of lists. Each element of `plots` is a list, where the first element is a pedigree, and the remaining elements are passed on to `plot.ped`. These elements must be correctly named. See examples below.

widths	A numeric vector of relative widths of the subplots. Recycled to length(plots) if necessary, before passed on to <code>layout()</code> . Note that the vector does not need to sum to 1.
groups	A list of vectors, each consisting of consecutive integers, indicating subplots to be grouped. By default the grouping follows the list structure of plots.
titles	A character vector of titles for each group. Overrides titles given in individuals subplots.
frames	A logical indicating if groups should be framed.
fmar	A single number in the interval $[0, 0.5)$ controlling the position of the frames.
source	NULL (default), or the name or index of an element of plots. If given, marker data is temporarily transferred from this to all the other pedigrees. This may save some typing when plotting the same genotypes on several pedigrees.
dev.height, dev.width	The dimensions of the new plot window. If these are NA suitable values are guessed from the pedigree sizes.
newdev	A logical, indicating if a new plot window should be opened.
verbose	A logical.
...	Further arguments passed on to each call to <code>plot.ped()</code> .

Details

Note that for tweaking dev.height and dev.width the function `dev.size()` is useful to determine the size of the active device.

dev.off()

```

print.nucleus	<i>S3 methods</i>
---------------	-------------------

Description

S3 methods

Usage

```
## S3 method for class 'nucleus'
print(x, ...)
```

Arguments

x	An object
...	Not used

print.ped	<i>Printing pedigrees</i>
-----------	---------------------------

Description

Print a ped object using original labels.

Usage

```
## S3 method for class 'ped'
print(x, ..., markers, verbose = TRUE)
```

Arguments

x	object of class ped.
...	(optional) arguments passed on to <code>print.data.frame()</code> .
markers	(optional) vector of marker indices. If missing, and x has less than 10 markers, they are all displayed. If x has 10 or more markers, the first 5 are displayed.
verbose	If TRUE, a message is printed if only the first 5 markers are printed. (See above).

Details

This first calls `as.data.frame.ped()` and then prints the resulting data.frame. The data.frame is returned invisibly.

randomPed

Random pedigree

Description

Generate a random connected pedigree by applying random mating starting from a finite population.

Usage

```
randomPed(
  n,
  f = 2,
  maxDirectGap = 1,
  selfing = FALSE,
  seed = NULL,
  g = NULL,
  founders = NULL
)
```

Arguments

n	A positive integer: the total number of individuals. Must be at least 3.
f	A positive integer: the number of founders. Must be at least 2 unless selfing is allowed.
maxDirectGap	An integer; the maximum distance between direct descendants allowed to mate. For example, the default value of 1 allows parent-child mating, but not grandparent-grandchild. Set to Inf or NULL to remove all restrictions.
selfing	A logical indicating if selfing is allowed. Default: FALSE.
seed	An integer seed for the random number generator (optional).
g, founders	Deprecated arguments.

Details

Starting from an initial set of f singletons, a sequence of $n-f$ random matings is performed. The sampling of parents in each mating is set up to ensure that the final result is connected.

Value

A connected pedigree returned as a ped object.

Examples

```
plot(randomPed(7, f = 2, seed = 12))

# Disallow mating between direct descendants
plot(randomPed(7, f = 2, seed = 12, maxDirectGap = 0))

# No restrictions on mating between direct descendants
plot(randomPed(7, f = 2, seed = 12, maxDirectGap = Inf))

# Allow selfing
y = randomPed(5, f = 2, seed = 2, selfing = TRUE)
hasSelfing(y)
y
plot(y, arrows = TRUE)
```

readPed

Read a pedigree from file

Description

Reads a text file in pedigree format, or something fairly close to it.

Usage

```
readPed(
  pedfile,
  colSep = "",
  header = NA,
  famid_col = NA,
  id_col = NA,
  fid_col = NA,
  mid_col = NA,
  sex_col = NA,
  marker_col = NA,
  locusAttributes = NULL,
  missing = 0,
  sep = NULL,
  validate = TRUE,
```

```
    ...
  )
```

Arguments

pedfile	A file name
colSep	A column separator character, passed on as the sep argument of <code>read.table()</code> . The default is to separate on white space, that is, one or more spaces, tabs, newlines or carriage returns. (Note: the parameter sep is used to indicate allele separation in genotypes.)
header	A logical. If NA, the program will interpret the first line as a header line it contains both "id" and "sex" as part of some entries (ignoring case).
famid_col	Index of family ID column. If NA, the program looks for a column named "famid" (ignoring case).
id_col	Index of individual ID column. If NA, the program looks for a column named "id" (ignoring case).
fid_col	Index of father ID column. If NA, the program looks for a column named "fid" (ignoring case).
mid_col	Index of mother ID column. If NA, the program looks for a column named "mid" (ignoring case).
sex_col	Index of column with gender codes (0 = unknown; 1 = male; 2 = female). If NA, the program looks for a column named "sex" (ignoring case). If this is not found, genders of parents are deduced from the data, leaving the remaining as unknown.
marker_col	Index vector indicating columns with marker alleles. If NA, all columns to the right of all pedigree columns are used. If sep (see below) is non-NULL, each column is interpreted as a genotype column and split into separate alleles with <code>strsplit(..., split = sep, fixed = TRUE)</code> .
locusAttributes	Passed on to <code>setMarkers()</code> (see explanation there).
missing	Passed on to <code>setMarkers()</code> (see explanation there).
sep	Passed on to <code>setMarkers()</code> (see explanation there).
validate	A logical indicating if the pedigree structure should be validated.
...	Further parameters passed on to <code>read.table()</code> , e.g. <code>comment.char</code> and <code>quote</code> .

Details

If there are no headers, and no column information is provided by the user, the program assumes the following column order:

- family ID (optional; guessed from the data)
- individual ID
- father's ID
- mother's ID

- sex
- marker data (remaining columns)

Reading SNP data:

Adding the argument `locusAttributes = "snp-AB"`, sets all markers to be equiprequent SNPs with alleles A and B. Moreover, the letters A and B may be replaced by other single-character letters or numbers, e.g., "snp-12" gives alleles 1 and 2.

Value

A `ped` object or a list of such.

Examples

```
tf = tempfile()

### Write and read a trio
trio = data.frame(id = 1:3, fid = c(0,0,1), mid = c(0,0,2), sex = c(1,2,1))
write.table(trio, file = tf, row.names = FALSE)
readPed(tf)

# With marker data in one column
trio.marker = cbind(trio, M = c("1/1", "2/2", "1/2"))
write.table(trio.marker, file = tf, row.names = FALSE)
readPed(tf)

# With marker data in two allele columns
trio.marker2 = cbind(trio, M.1 = c(1,2,1), M.2 = c(1,2,2))
write.table(trio.marker2, file = tf, row.names = FALSE)
readPed(tf)

### Two singletons in the same file
singles = data.frame(id = c("S1", "S2"),
                    fid = c(0,0), mid = c(0,0), sex = c(2,1),
                    M = c("9/14.2", "9/9"))
write.table(singles, file = tf, row.names = FALSE)
readPed(tf)

### Two trios in the same file
trio2 = cbind(famid = rep(c("trio1", "trio2"), each = 3), rbind(trio, trio))

# Without column names
write.table(trio2, file = tf, row.names = FALSE)
readPed(tf)

# With column names
write.table(trio2, file = tf, col.names = FALSE, row.names = FALSE)
readPed(tf, famid = 1, id = 2, fid = 3, mid = 4, sex = 5)

# Cleanup
unlink(tf)
```

relabel	<i>Get or modify pedigree labels</i>
---------	--------------------------------------

Description

Functions for getting or changing the ID labels of pedigree members.

Usage

```
relabel(
  x,
  new = "asPlot",
  old = labels(x),
  reorder = FALSE,
  returnLabs = FALSE,
  .alignment = NULL
)

## S3 method for class 'ped'
labels(object, ...)

## S3 method for class 'list'
labels(object, ...)
```

Arguments

x	A ped object or a list of such.
new	Either a character vector containing new labels, or one of the special words "asPlot" (default) or "generations". See Details and Examples.
old	A vector of ID labels, of the same length as new. (Ignored if new is one of the special words.)
reorder	A logical. If TRUE, <code>reorderPed()</code> is called on x after relabelling. Default: FALSE.
returnLabs	A logical. If TRUE, the new labels are returned as a named character vector.
.alignment	A list of alignment details for x, used if new equals "asPlot" or "generations". If not supplied, this is computed internally with <code>.pedAlignment()</code> .
object	A ped object
...	Not used

Details

By default, `relabel(x)` relabels everyone as 1, 2, ..., in the order given by the plot (top to bottom; left to right).

Alternatively, `relabel(x, "generations")` labels the members in the top generation I-1, I-2, ..., in the second generation II-1, II-2, ..., etc.

Value

- `labels()` returns a character vector containing the ID labels of all pedigree members. If the input is a list of ped objects, the output is a list of character vectors.
- `relabel()` by default returns a ped object similar to `x`, but with modified labels. If `returnLabs` is `TRUE`, the new labels are returned as a named character vector

See Also

[ped\(\)](#)

Examples

```
x = nuclearPed()
x
labels(x)

y = relabel(x, new = "girl", old = 3)
y

# Back to the numeric labels
z = relabel(y)
stopifnot(identical(x,z))

# Generation labels
relabel(x, "generations")
```

setMutmod

Set a mutation model

Description

This function offers a convenient way to set or modify mutation models to markers attached to a pedigree. It wraps `pedmut::mutationModel()`, which does the main work of creating the models, but relieves the user from having to loop through the markers in order to supply the correct alleles and frequencies for each marker. (This function supersedes `pedprobr::setMutationModel()`.)

Usage

```
setMutmod(x, markers = NULL, ..., update = FALSE)
```

Arguments

<code>x</code>	A ped object or a list of such.
<code>markers</code>	A vector of names or indices referring to markers attached to <code>x</code> . (Default: All markers.)
<code>...</code>	Arguments forwarded to <code>pedmut::mutationModel()</code> , e.g., <code>model</code> , <code>rate</code> , etc.

update A logical. If TRUE, existing mutation models (if present) are updated with the parameters specified in If FALSE (default), any previous models are ignored, and new mutation models are created from the parameters in

Details

Currently, the following models are implemented in the pedmut package:

- equal : All mutations equally likely; probability $1 - rate$ of no mutation
- proportional : Mutation probabilities are proportional to the target allele frequencies
- onestep: A mutation model for microsatellite markers, allowing mutations only to the nearest neighbours in the allelic ladder. For example, '10' may mutate to either '9' or '11', unless '10' is the lowest allele, in which case '11' is the only option. This model is not applicable to loci with non-integral microvariants.
- stepwise: A common model in forensic genetics, allowing different mutation rates between integer alleles (like '16') and non-integer "microvariants" like '9.3'). Mutations also depend on the size of the mutation if the parameter 'range' differs from 1.
- custom : Allows any mutation matrix to be provided by the user, in the matrix parameter
- random : This produces a matrix of random numbers, where each row is normalised so that it sums to 1
- trivial : The identity matrix; i.e. no mutations are possible.

Value

An object similar to x.

Examples

```
### Example requires the pedmut package ###

if (requireNamespace("pedmut", quietly = TRUE)){

# A pedigree with 1 empty marker; attach 'equal' mutation model
x = nuclearPed(1) |>
  addMarker() |>
  setMutmod(model = "equal", rate = 0.01)

mutmod(x, 1)

# Update rate (but still "equal" model)
y = setMutmod(x, rate = 0.05, update = TRUE)
mutmod(y, 1)

# Change to stepwise model
z = setMutmod(x, model = "stepwise",
              rate = list(female = 0.01, male = 0.02),
              range = 0.1, rate2 = 1e-6)
mutmod(z, 1)
```

```
# Remove mutation model
w = setMutmod(x, model = NULL)
mutmod(w, 1)

}
```

setSNPs

Attach SNP loci to a pedigree

Description

Create and attach a list of empty SNP markers with specified position and allele frequencies.

Usage

```
setSNPs(x, snpData)
```

Arguments

x	A ped object.
snpData	A data frame with 6 columns. See Details.

Details

The data frame snpData should contain the following columns, in order:

- CHROM: Chromosome (character)
- MARKER: Marker name (character)
- MB: Physical position in megabases (numeric)
- A1: First allele (single-letter character)
- A2: Second allele (single-letter character)
- FREQ1: Allele frequency of A1 (number in $[\emptyset, 1]$)

The actual column names do not matter.

Each column must be of the stated type, or coercible to it. (For example, CHROM, A1 and A2 may be given as numbers, but will be internally converted to characters.)

Value

A copy of x with the indicated SNP markers attached.

Examples

```
snps = data.frame(
  CHROM = 1:2,
  MARKER = c("M1", "M2"),
  MB     = c(1.23, 2.34),
  A1     = c("A", "G"),
  A2     = c("C", "C"),
  FREQ1  = c(0.7, 0.12))

x = setSNPs(nuclearPed(), snpData = snps)

# Inspect the results:
getMap(x)
getFreqDatabase(x)
```

<code>sortGenotypes</code>	<i>Sort the alleles in each genotype</i>
----------------------------	--

Description

Ensure that all genotypes are sorted internally. For example, if a marker attached to `x` has alleles 1 and 2, then running this function will replace all genotypes "2/1" by "1/2".

Usage

```
sortGenotypes(x)
```

Arguments

`x` A ped object or a list of such

Value

An object identical to `x` except that the all genotypes are sorted.

Examples

```
x = singleton(1)

# Various markers with misordered genotypes
m1 = marker(x, `1` = "2/1")
m2 = marker(x, `1` = "b/a")
m3 = marker(x, `1` = "100.3/99.1")
x = setMarkers(x, list(m1, m2, m3))
x

# Sort all genotypes
```

```

y = sortGenotypes(x)
y

# Also works when input is a list of peds
sortGenotypes(list(x, x))

```

transferMarkers	<i>Transfer marker data</i>
-----------------	-----------------------------

Description

Transfer marker data between pedigrees. Any markers attached to the target are overwritten.

Usage

```

transferMarkers(
  from,
  to,
  ids = NULL,
  idsFrom = ids,
  idsTo = ids,
  erase = TRUE,
  matchNames = TRUE,
  checkSex = FALSE
)

```

Arguments

from	A ped or singleton object, or a list of such objects.
to	A ped or singleton object, or a list of such objects.
ids	A vector of ID labels. This should be used only if the individuals have the same name in both pedigrees; otherwise use <code>idsFrom</code> and <code>idsTo</code> instead.
idsFrom, idsTo	Vectors of equal length, denoting source individuals (in the <code>from</code> pedigree) and target individuals (in the <code>to</code> pedigree), respectively.
erase	A logical. If <code>TRUE</code> (default), all markers attached to <code>to</code> are erased prior to transfer, and new marker objects are created with the same attributes as in <code>from</code> . If <code>FALSE</code> no new marker objects are attached to <code>to</code> . Only the genotypes of the <code>ids</code> individuals are modified, while genotypes for other pedigree members - and marker attributes - remain untouched.
matchNames	A logical, only relevant if <code>erase = FALSE</code> . If <code>matchNames = TRUE</code> (default) marker names are used to ensure genotypes are transferred into the right markers. The output contains only markers present in <code>from</code> , in the same order. (An error is raised if the markers are not named.)
checkSex	A logical. If <code>TRUE</code> , it is checked that <code>fromIds</code> and <code>toIds</code> have the same sex. Default: <code>FALSE</code> .

Details

By default, genotypes are transferred between all individuals present in both pedigrees.

Value

A ped object (or a list of such) similar to `to`, but where all individuals also present in `from` have marker genotypes copied over. Any previous marker data is erased.

Examples

```
x = nuclearPed(fa = "A", mo = "B", child = "C")
x = addMarker(x, A = "1/2", B = "1/1", C = "1/2", name = "M1")

y = list(singleton("A"), nuclearPed(fa = "D", mo = "B", child = "C"))

# By default all common individuals are transferred
transferMarkers(x, y)

# Transfer data for the boy only
transferMarkers(x, y, ids = "C")

# Transfer without first erasing the target markers
z = nuclearPed(fa = "A", mo = "B", child = "C")
z = addMarker(z, A = "1/1", alleles = 1:2, name = "M1")

transferMarkers(x, z, ids = "C", erase = FALSE)
transferMarkers(x, z, ids = "C", erase = TRUE) # note the difference
```

 validatePed

Pedigree errors

Description

Validate the internal pedigree structure. The input may be either a (possibly malformed) `ped()` object, or its defining vectors `id`, `fid`, `mid`, `sex`.

Usage

```
validatePed(x = NULL, id = NULL, fid = NULL, mid = NULL, sex = NULL)
```

Arguments

<code>x</code>	A ped object.
<code>id</code>	A vector (numeric or character) of individual ID labels.
<code>fid</code>	A vector of the same length as <code>id</code> , containing the labels of the fathers. In other words <code>fid[i]</code> is the father of <code>id[i]</code> , or 0 if <code>id[i]</code> is a founder.

mid	A vector of the same length as id, containing the labels of the mothers. In other words mid[i] is the mother of id[i], or 0 if id[i] is a founder.
sex	A numeric of the same length as id, describing the genders of the individuals (in the same order as id.) Each entry must be either 1 (=male), 2 (=female) or 0 (=unknown).

Value

If no errors are detected, the function returns NULL invisibly. Otherwise, messages describing the errors are printed to the screen and an error is raised.

Examples

```
x = nuclearPed()
validatePed(x)

# Various errors
# validatePed(id = c(1,2), fid = c(2,0), mid = c(0,1), sex = c(1,2))
```

writePed	<i>Write a pedigree to file</i>
----------	---------------------------------

Description

Write a pedigree to file

Usage

```
writePed(
  x,
  prefix,
  what = "ped",
  famid = is.pedList(x),
  header = TRUE,
  merlin = FALSE,
  verbose = TRUE
)
```

Arguments

x	A ped object
prefix	A character string giving the prefix of the files. For instance, if prefix = "myped" and what = c("ped", "map"), the output files are "myped.ped" and "myped.map" in the current directory. Paths to other folder may be included, e.g. prefix = "path-to-my-dir/myped".

what	A subset of the character vector <code>c("ped", "map", "dat", "freq")</code> , indicating which files should be created. By default only the "ped" file is created. This option is ignored if <code>merlin = TRUE</code> .
famid	A logical indicating if family ID should be included as the first column in the ped file. The family ID is taken from <code>famid(x)</code> . If <code>x</code> is a list of pedigrees, the family IDs are taken from <code>names(x)</code> , or if this is <code>NULL</code> , the component-wise <code>famid()</code> values. Missing values are replaced by natural numbers. This option is ignored if <code>merlin = TRUE</code> .
header	A logical indicating if column names should be included in the ped file. This option is ignored if <code>merlin = TRUE</code> .
merlin	A logical. If <code>TRUE</code> , "ped", "map", "dat" and "freq" files are written in a format readable by the MERLIN software. In particular MERLIN requires non-numerical allele labels in the frequency file.
verbose	A logical.

Value

A character vector with the file names.

Examples

```
x = nuclearPed(1)
x = addMarker(x, "3" = "a/b", name = "m1")

# Write to file
fn = writePed(x, prefix = tempfile("test"))

# Read
y = readPed(fn)

stopifnot(identical(x, y))
```
