

# Package ‘qgcomp’

July 13, 2019

**Title** Quantile G-Computation

**Version** 1.1.0

**Date** 2019-07-13

**Author** Alexander Keil [aut, cre]

**Maintainer** Alexander Keil <akeil@unc.edu>

**Description** G-computation for a set of time-fixed exposures with quantile-based basis functions, possibly under linearity and homogeneity assumptions. This approach estimates a regression line corresponding to the expected change in the outcome (on the link basis) given a simultaneous increase in the quantile-based category for all exposures. Reference: Alexander P. Keil, Jessie P. Buckley, Katie M. O'Brien, Kelly K. Ferguson, Shanshan Zhao Alexandra J. White (2019) A quantile-based g-computation approach to addressing the effects of exposure mixtures; <arXiv:1902.04200> [stat.ME].

**License** GPL (>= 2)

**Depends** ggplot2 (>= 2.5), grDevices, grid, gridExtra, R (>= 3.0), stats (>= 3.0), survival

**Suggests** knitr (>= 1.0)

**VignetteBuilder** knitr

**Encoding** UTF-8

**Language** en-US

**LazyData** true

**RoxygenNote** 6.1.1

**NeedsCompilation** no

**Repository** CRAN

---

coxmsm.fit	<i>fitting marginal structural model (MSM) based on g-computation with quantized exposures</i>
------------	--

---

### Description

this is an internal function called by `qgcomp.cox.noboot`, `qgcomp.cox.boot`, and `qgcomp.cox.noboot`, but is documented here for clarity. Generally, users will not need to call this function directly.

### Usage

```
coxmsm.fit(f, qdata, intvals, expnms, rr = TRUE, main = TRUE,
           degree = 1, id = NULL, ...)
```

### Arguments

f	an r formula representing the conditional model for the outcome, given all exposures and covariates. Interaction terms that include exposure variables should be represented via the <code>I</code> function
qdata	a data frame with quantized exposures
intvals	sequence, the sequence of integer values that the joint exposure is 'set' to for estimating the msm. For quantile g-computation, this is just 0:(q-1), where q is the number of quantiles of exposure.
expnms	a character vector with the names of the columns in qdata that represent the exposures of interest (main terms only!)
rr	logical, estimate log(risk ratio) (family='binomial' only)
main	logical, internal use: produce estimates of exposure effect (psi) and expected outcomes under g-computation and the MSM
degree	polynomial basis function for marginal model (e.g. degree = 2 allows that the relationship between the whole exposure mixture and the outcome is quadratic. Default=1)

```

id          (optional) NULL, or variable name indexing individual units of observation
           (only needed if analyzing data with multiple observations per id/cluster)
...        arguments to coxph (e.g. family)

```

### Details

This function first computes expected outcomes under hypothetical interventions to simultaneously set all exposures to a specific quantile. These predictions are based on g-computation, where the exposures are ‘quantized’, meaning that they take on ordered integer values according to their ranks, and the integer values are determined by the number of quantile cutpoints used. The function then takes these expected outcomes and fits an additional model (a marginal structural model) with the expected outcomes as the outcome and the intervention value of the exposures (the quantile integer) as the exposure. Under causal identification assumptions and correct model specification, the MSM yields a causal exposure-response representing the incremental change in the expected outcome given a joint intervention on all exposures.

### Examples

```
runif(1)
```

---

metals	<i>Simulated well water measurements in North Carolina: 16 metals, 6 water chemistry measures, and 2 health outcomes (y = continuous; disease_state = binary)</i>
--------	---

---

### Description

A dataset containing well water measurements and health outcomes for 253 individuals. All continuous variables are standardized to have mean 0, standard deviation 1.

### Usage

```
metals
```

### Format

A data frame with 253 rows and 24 variables:

```

y      continuous birth outcome
disease_state  binary birth outcome
arsenic  metal
barium   metal
cadmium  metal

```

**calcium** metal  
**chloride** metal  
**chromium** metal  
**copper** metal  
**iron** metal  
**lead** metal  
**magnesium** metal  
**manganese** metal  
**mercury** metal  
**selenium** metal  
**silver** metal  
**sodium** metal  
**zinc** metal  
**mage35** Binary covariate: maternal age > 35  
**nitrate** water chemistry measure  
**nitrite** water chemistry measure  
**sulfate** water chemistry measure  
**ph** water chemistry measure  
**total\_alkalinity** water chemistry measure  
**total\_hardness** water chemistry measure

---

msm.fit

*fitting marginal structural model (MSM) based on g-computation with quantized exposures*

---

## Description

This is an internal function called by `qgcomp`, `qgcomp.boot`, and `qgcomp.noboot`, but is documented here for clarity. Generally, users will not need to call this function directly.

## Usage

```
msm.fit(f, qdata, intvals, expnms, rr = TRUE, main = TRUE,  
        degree = 1, id = NULL, ...)
```

**Arguments**

f	an r formula representing the conditional model for the outcome, given all exposures and covariates. Interaction terms that include exposure variables should be represented via the <code>I</code> function
qdata	a data frame with quantized exposures
intvals	sequence, the sequence of integer values that the joint exposure is 'set' to for estimating the msm. For quantile g-computation, this is just 0:(q-1), where q is the number of quantiles of exposure.
expnms	a character vector with the names of the columns in qdata that represent the exposures of interest (main terms only!)
rr	logical, estimate log(risk ratio) (family='binomial' only)
main	logical, internal use: produce estimates of exposure effect (psi) and expected outcomes under g-computation and the MSM
degree	polynomial basis function for marginal model (e.g. degree = 2 allows that the relationship between the whole exposure mixture and the outcome is quadratic. Default=1)
id	(optional) NULL, or variable name indexing individual units of observation (only needed if analyzing data with multiple observations per id/cluster)
...	arguments to glm (e.g. family)

**Details**

This function first computes expected outcomes under hypothetical interventions to simultaneously set all exposures to a specific quantile. These predictions are based on g-computation, where the exposures are 'quantized', meaning that they take on ordered integer values according to their ranks, and the integer values are determined by the number of quantile cutpoints used. The function then takes these expected outcomes and fits an additional model (a marginal structural model) with the expected outcomes as the outcome and the intervention value of the exposures (the quantile integer) as the exposure. Under causal identification assumptions and correct model specification, the MSM yields a causal exposure-response representing the incremental change in the expected outcome given a joint intervention on all exposures.

**Examples**

```
set.seed(50)
dat <- data.frame(y=runif(200), x1=runif(200), x2=runif(200), z=runif(200))
X <- c('x1', 'x2')
qdat <- quantize(dat, X, q=4)$data
mod <- qgcomp::msm.fit(f=y ~ z + x1 + x2 + I(x1*x2),
  expnms = c('x1', 'x2'), qdata=qdat, intvals=1:4)
summary(mod$fit) # outcome regression model
summary(mod$msmfit) # msm fit (variance not valid - must be obtained via bootstrap)
```

---

msm.predict	<i>msm.predict: secondary prediction method for the MSM within a qg-compfit object.</i>
-------------	---

---

### Description

Makes predictions from the MSM (rather than the g-computation model) from a "qgcompfit" object. Generally, this should not be used in favor of the default `predict.qgcompfit` function. This function can only be used following the 'qgcomp.boot' function. For the 'qgcomp.noboot' function, `predict.qgcompfit` gives identical inference to predicting from an MSM.

get predicted values from a qgcompfit object from `qgcomp.boot`

### Usage

```
msm.predict(object, newdata = NULL)
```

### Arguments

object	"qgcompfit" object from 'qgcomp.boot' function
newdata	(optional) new set of data (data frame) with a variable called 'psi' representing the joint exposure level of all exposures under consideration

### Examples

```
set.seed(50)
dat <- data.frame(y=runif(50), x1=runif(50), x2=runif(50), z=runif(50))
obj <- qgcomp.boot(y ~ z + x1 + x2 + I(z*x1), exprms = c('x1', 'x2'), data=dat, q=4, B=10, seed=125)
dat2 <- data.frame(psi=seq(1,4, by=0.1))
summary(msm.predict(obj))
summary(msm.predict(obj, newdata=dat2))
```

---

plot.qgcompfit	<i>plot.qgcompfit: default plotting method for a qgcompfit object</i>
----------------	---

---

### Description

Plot a quantile g-computation object. For `qgcomp.noboot`, this function will create a butterfly plot of weights. For `qgcomp.boot`, this function will create a box plot with smoothed line overlaying that represents a non-parametric fit of a model to the expected outcomes in the population at each quantile of the joint exposures (e.g. '1' represents 'at the first quantile for every exposure')

### Usage

```
## S3 method for class 'qgcompfit'
plot(x, suppressprint = FALSE, ...)
```

**Arguments**

x	"qgcompfit" object from 'qgcomp.noboot' or 'qgcomp.boot' functions
suppressprint	If TRUE, suppresses the plot, rather than printing it by default (it can be saved as a ggplot2 object and used programmatically) (default = FALSE)
...	unused

**See Also**

[qgcomp.noboot](#), [qgcomp.boot](#), and [qgcomp](#)

**Examples**

```
set.seed(12)
dat <- data.frame(x1=(x1 <- runif(100)), x2=runif(100), x3=runif(100), z=runif(100),
                 y=runif(100)+x1+x1^2)
ft <- qgcomp.noboot(y ~ z + x1 + x2 + x3, expnms=c('x1','x2','x3'), data=dat, q=4)
ft
plot(ft)
# examining fit
plot(ft$fit, which=1) # residual vs. fitted is not straight line!

# using non-linear outcome model
ft2 <- qgcomp.boot(y ~ z + x1 + x2 + x3 + I(x1*x1), expnms=c('x1','x2','x3'),
                 data=dat, q=4, B=10)
ft2
plot(ft2$fit, which=1) # much better looking fit diagnostics suggests
# it is better to include interaction term for x
plot(ft2) # the msm predictions don't match up with a smooth estimate
# of the expected outcome, so we should consider a non-linear MSM
# using non-linear marginal structural model
ft3 <- qgcomp.boot(y ~ z + x1 + x2 + x3 + I(x1*x1), expnms=c('x1','x2','x3'),
                 data=dat, q=4, B=10, degree=2)
# plot(ft3$fit, which=1) - not run - this is identical to ft2 fit
plot(ft3) # the MSM estimates look much closer to the smoothed estimates
# suggesting the non-linear MSM fits the data better and should be used
# for inference about the effect of the exposure
```

---

predict.qgcompfit      *predict.qgcompfit: default prediction method for a qgcompfit object*

---

**Description**

get predicted values from a qgcompfit object, or make predictions in a new set of data based on the qgcompfit object. Note that when making predictions from an object from qgcomp.boot, the predictions are made from the g-computation model rather than the marginal structural model. Predictions from the marginal structural model can be obtained via [msm.predict](#)

**Usage**

```
## S3 method for class 'qgcompfit'
predict(object, expnms = NULL, newdata = NULL,
        type = "response", ...)
```

**Arguments**

object	"qgcompfit" object from 'qgcomp.noboot' or 'qgcomp.boot' functions
expnms	character vector of exposures of interest
newdata	(optional) new set of data with all predictors from "qgcompfit" object
type	(from predict.glm) the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.
...	arguments to predict.glm

**Examples**

```
set.seed(50)
dat <- data.frame(y=runif(50), x1=runif(50), x2=runif(50), z=runif(50))
obj1 <- qgcomp.noboot(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2)
obj2 <- qgcomp.boot(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2, B=10, seed=125)
set.seed(52)
dat2 <- data.frame(y=runif(50), x1=runif(50), x2=runif(50), z=runif(50))
summary(predict(obj1, expnms = c('x1', 'x2'), newdata=dat2))
summary(predict(obj2, expnms = c('x1', 'x2'), newdata=dat2))
```

---

print.qgcompfit      *default printing method for a qgcompfit object*

---

**Description**

Gives variable output depending on whether 'qgcomp.noboot' or 'qgcomp.boot' is called. For 'qgcomp.noboot' will output final estimate of joint exposure effect (similar to the 'index' effect in weighted quantile sums), as well as estimates of the 'weights' (standardized coefficients). For 'qgcomp.boot', the marginal effect is given, but no weights are reported since this approach generally incorporates non-linear models with interaction terms among exposures, which preclude weights with any useful interpretation.

**Usage**

```
## S3 method for class 'qgcompfit'
print(x, ...)
```

**Arguments**

x "qgcompfit" object from 'qgcomp', 'qgcomp.noboot' or 'qgcomp.boot' function  
 ... unused

**See Also**

[qgcomp.noboot](#), [qgcomp.boot](#), and [qgcomp](#)

**Examples**

```
set.seed(50)
dat <- data.frame(y=runif(50), x1=runif(50), x2=runif(50), z=runif(50))
obj1 <- qgcomp.noboot(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2)
obj2 <- qgcomp.boot(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2, B=10, seed=125)
# does not need to be explicitly called, but included here for clarity
print(obj1)
print(obj2)
```

---

qgcomp

*estimation of quantile g-computation fit*

---

**Description**

This function automatically selects between `qgcomp.noboot` and `qgcomp.boot` to select the most efficient approach to estimate the average expected change in the (log) outcome per quantile increase in the joint exposure to all exposures in 'expnms'

**Usage**

```
qgcomp(f, data = data, family = gaussian(), rr = TRUE, ...)
```

**Arguments**

f R style formula  
 data data frame  
 family 'gaussian()' or 'binomial()'  
 rr logical: if using binary outcome and `rr=TRUE`, `qgcomp.boot` will estimate risk ratio rather than odds ratio. Note, to get population average effect estimates for a binary outcome, set `rr=TRUE` (default: ORs are generally not of interest as population average effects, so if `rr=FALSE` then a conditional OR will be estimated, which cannot be interpreted as a population average effect  
 ... arguments to `qgcomp.noboot` or `qgcomp.boot` (e.g. q)

**Value**

a qgcompfit object, which contains information about the effect measure of interest ( $\psi$ ) and associated variance ( $\text{var}(\psi)$ ), as well as information on the model fit ( $\text{fit}$ ) and possibly information on the marginal structural model ( $\text{msmfit}$ ) used to estimate the final effect estimates (qgcomp.boot only). If appropriate, weights are also reported.

**See Also**

[qgcomp.noboot](#) and [qgcomp.boot](#)

**Examples**

```
set.seed(50)
dat <- data.frame(y=runif(50), x1=runif(50), x2=runif(50), z=runif(50))
qgcomp.noboot(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2)
qgcomp.boot(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2, B=10, seed=125)
# automatically selects appropriate method
qgcomp(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2)
# note for binary outcome this will
dat <- data.frame(y=rbinom(50, 1, 0.5), x1=runif(50), x2=runif(50), z=runif(50))
qgcomp.noboot(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2, family=binomial())
qgcomp.boot(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2, B=10, seed=125,
  family=binomial())
# automatically selects appropriate method
qgcomp(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2, family=binomial())
qgcomp(y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2, family=binomial(), rr=TRUE)
```

---

qgcomp.boot	<i>estimation of quantile g-computation fit, using bootstrap confidence intervals</i>
-------------	---

---

**Description**

This function yields population average effect estimates for both continuous and binary outcomes

**Usage**

```
qgcomp.boot(f, data, expnms = NULL, q = 4, breaks = NULL,
  id = NULL, alpha = 0.05, B = 200, rr = TRUE, degree = 1,
  seed = NULL, ...)
```

**Arguments**

f	R style formula
data	data frame
expnms	character vector of exposures of interest

q	NULL or number of quantiles used to create quantile indicator variables representing the exposure variables. If NULL, then gcomp proceeds with untransformed version of exposures in the input datasets (useful if data are already transformed, or for performing standard g-computation)
breaks	(optional) NULL, or a list of (equal length) numeric vectors that characterize the minimum value of each category for which to break up the variables named in expnms. This is an alternative to using 'q' to define cutpoints.
id	(optional) NULL, or variable name indexing individual units of observation (only needed if analyzing data with multiple observations per id/cluster)
alpha	alpha level for confidence limit calculation
B	integer: number of bootstrap iterations (this should typically be $\geq 200$ , though it is set lower in examples to improve run-time).
rr	logical: if using binary outcome and rr=TRUE, qgcomp.boot will estimate risk ratio rather than odds ratio
degree	polynomial basis function for marginal model (e.g. degree = 2 allows that the relationship between the whole exposure mixture and the outcome is quadratic).
seed	integer or NULL: random number seed for replicable bootstrap results
...	arguments to glm (e.g. family)

### Details

Estimates correspond to the average expected change in the (log) outcome per quantile increase in the joint exposure to all exposures in 'expnms'. Test statistics and confidence intervals are based on a non-parametric bootstrap, using the standard deviation of the bootstrap estimates to estimate the standard error. The bootstrap standard error is then used to estimate Wald-type confidence intervals. Note that no bootstrapping is done on estimated quantiles of exposure, so these are treated as fixed quantities

### Value

a qgcompfit object, which contains information about the effect measure of interest (psi) and associated variance (var.psi), as well as information on the model fit (fit) and information on the marginal structural model (msmfit) used to estimate the final effect estimates.

**Examples**

```
runif(1)
```

---

qgcomp.cox.noboot

*estimation of quantile g-computation fit for a survival outcome*

---

## Description

This function performs quantile g-computation in a survival setting. The approach estimates the covariate-conditional hazard ratio for a joint change of 1 quantile in each exposure variable specified in `expnms` parameter

## Usage

```
qgcomp.cox.noboot(f, data, expnms = NULL, q = 4, breaks = NULL,
  id = NULL, alpha = 0.05, ...)
```

## Arguments

<code>f</code>	R style formula
<code>data</code>	data frame
<code>expnms</code>	character vector of exposures of interest
<code>q</code>	NULL or number of quantiles used to create quantile indicator variables representing the exposure variables. If NULL, then <code>gcomp</code> proceeds with untransformed version of exposures in the input datasets (useful if data are already transformed, or for performing standard g-computation)
<code>breaks</code>	(optional) NULL, or a list of (equal length) numeric vectors that characterize the minimum value of each category for which to break up the variables named in <code>expnms</code> . This is an alternative to using <code>'q'</code> to define cutpoints.
<code>id</code>	(optional) NULL, or variable name indexing individual units of observation (only needed if analyzing data with multiple observations per <code>id</code> /cluster)
<code>alpha</code>	alpha level for confidence limit calculation
<code>...</code>	arguments to <code>glm</code> (e.g. family)

## Details

For survival outcomes (as specified using methods from the `survival` package), this yields a conditional log hazard ratio representing a change in the expected conditional hazard (conditional on covariates) from increasing every exposure by 1 quantile. In general, this quantity is not equivalent to g-computation estimates. Hypothesis test statistics and 95 estimate variance of a linear combination of random variables.

## Value

a `qgcompfit` object, which contains information about the effect measure of interest (`psi`) and associated variance (`var.psi`), as well as information on the model fit (`fit`) and information on the weights/standardized coefficients in the positive (`pweights`) and negative (`nweight`) directions.

**Examples**

```
runif(1)
```

---

qgcomp.noboot	<i>estimation of quantile g-computation fit (continuous outcome) or conditional quantile odds ratio (binary outcome)</i>
---------------	--

---

**Description**

This function mimics the output of a weighted quantile sums regression in large samples.

**Usage**

```
qgcomp.noboot(f, data, expnms = NULL, q = 4, breaks = NULL,
  id = NULL, alpha = 0.05, ...)
```

**Arguments**

f	R style formula
data	data frame
expnms	character vector of exposures of interest
q	NULL or number of quantiles used to create quantile indicator variables representing the exposure variables. If NULL, then gcomp proceeds with untransformed version of exposures in the input datasets (useful if data are already transformed, or for performing standard g-computation)
breaks	(optional) NULL, or a list of (equal length) numeric vectors that characterize the minimum value of each category for which to break up the variables named in expnms. This is an alternative to using 'q' to define cutpoints.
id	(optional) NULL, or variable name indexing individual units of observation (only needed if analyzing data with multiple observations per id/cluster)
alpha	alpha level for confidence limit calculation
...	arguments to glm (e.g. family)

**Details**

For continuous outcomes, under a linear model with no interaction terms, this is equivalent to g-computation of the effect of increasing every exposure by 1 quantile. For binary outcomes, this yields a conditional log odds ratio representing the change in the expected conditional odds (conditional on covariates) from increasing every exposure by 1 quantile. In general, the latter quantity is not equivalent to g-computation estimates. Hypothesis test statistics and 95 estimate variance of a linear combination of random variables.

**Value**

a `qgcompfit` object, which contains information about the effect measure of interest ( $\psi$ ) and associated variance ( $\text{var}(\psi)$ ), as well as information on the model fit (`fit`) and information on the weights/standardized coefficients in the positive (`pweights`) and negative (`nweight`) directions.

**See Also**

[qgcomp.boot](#), and [qgcomp](#)

**Examples**

```
set.seed(50)
dat <- data.frame(y=runif(50), x1=runif(50), x2=runif(50), z=runif(50))
qgcomp.noboot(f=y ~ z + x1 + x2, expnms = c('x1', 'x2'), data=dat, q=2)
```

---

quantize	<i>create variables representing indicator functions with cutpoints defined by quantiles</i>
----------	--

---

**Description**

This function creates categorical variables in place of the exposure variables named in `'expnms.'` For example, a continuous exposure `'x1'` will be replaced in the output data by another `'x1'` that takes on values  $0:(q-1)$ , where, for example, the value 1 indicates that the original `x1` value falls between the first and the second quantile.

**Usage**

```
quantize(data, expnms, q = 4, breaks = NULL)
```

**Arguments**

<code>data</code>	a data frame
<code>expnms</code>	a character vector with the names of the columns to be quantized
<code>q</code>	integer, number of quantiles used in creating quantized variables
<code>breaks</code>	(optional) list of (equal length) numeric vectors that characterize the minimum value of each category for which to break up the variables named in <code>expnms</code> . This is an alternative to using <code>'q'</code> to define cutpoints.

**Details**

This function is a vectorized version of `'quantile_f'` from the `'gWQS'` package that also allows the use of externally defined breaks

**Examples**

```

set.seed(1232)
dat = data.frame(y=runif(100), x1=runif(100), x2=runif(100), z=runif(100))
qdata = quantize(data=dat, expnms=c("x1", "x2"), q=4)
table(qdata$data$x1)
table(qdata$data$x2)
summary(dat[c("y", "z")]);summary(qdata$data[c("y", "z")]) # not touched
dat = data.frame(y=runif(100), x1=runif(100), x2=runif(100), z=runif(100))
# using 'breaks' requires specifying min and max (the qth quantile)
# example with theoretical quartiles (could be other relevant values)
qdata2 = quantize(data=dat, expnms=c("x1", "x2"),
  breaks=list(c(-1e64, .25, .5, .75, 1e64),
    c(-1e64, .25, .5, .75, 1e64)
  ))
table(qdata2$data$x1)
table(qdata2$data$x2)

```

---

se_comb	<i>Calculate standard error of weighted linear combination of random variables</i>
---------	--

---

**Description**

This function uses the Delta method to calculate standard errors that

**Usage**

```
se_comb(expnms, covmat, grad = NULL)
```

**Arguments**

expnms	a character vector with the names of the columns to be of interest in the covariance matrix for a which a standard error will be calculated (e.g. same as expnms in qgcomp fit)
covmat	covariance matrix for parameters, e.g. from a model or bootstrap procedure
grad	the "weight" vector for calculating the contribution of each variable in expnms to the final standard error. For a linear combination, this is equal to a vector of ones (and is set automatically). Or can be calculated via the grad.poly procedure, in the case of coming up with proper weights when the combination of expnms derives from a polynomial function (as in qgcomp.boot with degree>1).

**Details**

This function is a vectorized version of 'quantile\_f' from the 'gWQS' package that also allows the use of externally defined breaks usage: qgcomp:::se\_comb(expnms='x', covmat=summary(lmfit)\$cov.scaled) E.g. here is simple version of the delta method for a linear combination:  $f(x) = x_1 + x_2 + x_3$  given gradient vector  $G = [d(f(x))/dx_1 = 1, d(f(x))/dx_2 = 1, d(f(x))/dx_3 = 1]$  t(G)

**Examples**

```
vcov = rbind(c(1.2, .9),c(.9, 2.0))
colnames(vcov) <- rownames(vcov) <- expnms <- c("x1", "x2")
qgcomp:::se_comb(expnms, vcov, c(1, 0))^2 # returns the given variance
qgcomp:::se_comb(expnms, vcov, c(1, 1)) # default linear MSM fit: all exposures
# have equal weight
qgcomp:::se_comb(expnms, vcov, c(.3, .1)) # used when one exposure contributes
# to the overall fit more than others = d(msmeffect)/dx
```
