Package ‘rsample’

August 8, 2022

Title General Resampling Infrastructure
Version 1.1.0
Maintainer Julia Silge <julia.silge@rstudio.com>
Description Classes and functions to create and summarize different types
    of resampling objects (e.g. bootstrap, cross-validation).

.get_fingerprint

Obtain a identifier for the resamples

Description

This function returns a hash (or NA) for an attribute that is created when the rset was initially constructed. This can be used to compare with other resampling objects to see if they are the same.
Usage

.add_resample_id

Arguments

x

An rset or tune_results object.

... Not currently used.

Value

A character value or NA_character_ if the object was created prior to rsample version 0.1.0.

Examples

set.seed(1)
.add_fingerprint(vfold_cv(mtcars))

set.seed(1)
.add_fingerprint(vfold_cv(mtcars))

set.seed(2)
.add_fingerprint(vfold_cv(mtcars))

set.seed(1)
.add_fingerprint(vfold_cv(mtcars, repeats = 2))
Arguments

.data A data frame
.split A single rset object.
dots A single logical: should the id columns be prefixed with a "." to avoid name conflicts with .data?

Value

An updated data frame.

See Also

labels.rsplit

Examples

library(dplyr)

set.seed(363)
car_folds <- vfold_cv(mtcars, repeats = 3)

analysis(car_folds$splits[[1]]) %>%
  add_resample_id(car_folds$splits[[1]]) %>%
  head()

car_bt <- bootstraps(mtcars)

analysis(car_bt$splits[[1]]) %>%
  add_resample_id(car_bt$splits[[1]]) %>%
  head()
as.data.frame.rsplit

Arguments

- **data**: A data frame.
- **...**: Not currently used.

Value

A tibble with a single row and classes `apparent`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and one column called `id` that has a character string with the resample identifier.

Examples

```r
apparent(mtcars)
```

Convert an `rsplit` object to a data frame

Description

The analysis or assessment code can be returned as a data frame (as dictated by the data argument) using `as.data.frame.rsplit`. `analysis` and `assessment` are shortcuts.

Usage

```r
## S3 method for class 'rsplit'
as.data.frame(x, row.names = NULL, optional = FALSE, data = "analysis", ...)
```

```r
analysis(x, ...)
```

```r
assessment(x, ...)
```

Arguments

- **x**: An `rsplit` object.
- **row.names**: NULL or a character vector giving the row names for the data frame. Missing values are not allowed.
- **optional**: A logical: should the column names of the data be checked for legality?
- **data**: Either "analysis" or "assessment" to specify which data are returned.
- **...**: Additional arguments to be passed to or from methods. Not currently used.

Examples

```r
library(dplyr)
set.seed(104)
folds <- vfold_cv(mtcars)
model_data_1 <- folds$splits[[1]] %>% analysis()
holdout_data_1 <- folds$splits[[1]] %>% assessment()
```
Description

A bootstrap sample is a sample that is the same size as the original data set that is made using replacement. This results in analysis samples that have multiple replicates of some of the original rows of the data. The assessment set is defined as the rows of the original data that were not included in the bootstrap sample. This is often referred to as the “out-of-bag” (OOB) sample.

Usage

```r
bootstraps(
  data,
  times = 25,
  strata = NULL,
  breaks = 4,
  pool = 0.1,
  apparent = FALSE,
  ...
)
```

Arguments

- `data`: A data frame.
- `times`: The number of bootstrap samples.
- `strata`: A variable in `data` (single character or name) used to conduct stratified sampling. When not `NULL`, each resample is created within the stratification variable. Numeric `strata` are binned into quartiles.
- `breaks`: A single number giving the number of bins desired to stratify a numeric stratification variable.
- `pool`: A proportion of data used to determine if a particular group is too small and should be pooled into another group. We do not recommend decreasing this argument below its default of 0.1 because of the dangers of stratifying groups that are too small.
- `apparent`: A logical. Should an extra resample be added where the analysis and holdout subset are the entire data set. This is required for some estimators used by the `summary` function that require the apparent error rate.
- `...`: Not currently used.

Details

The argument `apparent` enables the option of an additional “resample” where the analysis and assessment data sets are the same as the original data set. This can be required for some types of analysis of the bootstrap results.
With a strata argument, the random sampling is conducted within the stratification variable. This can help ensure that the resamples have equivalent proportions as the original data set. For a categorical variable, sampling is conducted separately within each class. For a numeric stratification variable, strata is binned into quartiles, which are then used to stratify. Strata below 10% of the total are pooled together; see `make_strata()` for more details.

**Value**

A tibble with classes `bootstraps`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and a column called `id` that has a character string with the resample identifier.

**Examples**

```r
bootstraps(mtcars, times = 2)
bootstraps(mtcars, times = 2, apparent = TRUE)

library(purrr)
library(modeldata)
data(wa_churn)

set.seed(13)
resample1 <- bootstraps(wa_churn, times = 3)
map_dbl(resample1$splits, function(x) {
  dat <- as.data.frame(x)$churn
  mean(dat == "Yes")
})

set.seed(13)
resample2 <- bootstraps(wa_churn, strata = churn, times = 3)
map_dbl(resample2$splits, function(x) {
  dat <- as.data.frame(x)$churn
  mean(dat == "Yes")
})

set.seed(13)
resample3 <- bootstraps(wa_churn, strata = tenure, breaks = 6, times = 3)
map_dbl(resample3$splits, function(x) {
  dat <- as.data.frame(x)$churn
  mean(dat == "Yes")
})
```
complement  

**Determine the Assessment Samples**

**Description**

This method and function help find which data belong in the analysis and assessment sets.

**Usage**

complement(x, ...)

## S3 method for class 'rsplit'
complement(x, ...)

## S3 method for class 'rof_split'
complement(x, ...)

## S3 method for class 'sliding_window_split'
complement(x, ...)

## S3 method for class 'sliding_index_split'
complement(x, ...)

## S3 method for class 'sliding_period_split'
complement(x, ...)

## S3 method for class 'apparent_split'
complement(x, ...)

**Arguments**

- **x**  
  An rsplit object
- **...**  
  Not currently used

**Details**

Given an rsplit object, complement() will determine which of the data rows are contained in the assessment set. To save space, many of the rsplit objects will not contain indices for the assessment split.

**Value**

A integer vector.

**See Also**

populate()
Examples

```r
set.seed(28432)
fold_rs <- vfold_cv(mtcars)
head(fold_rs$splits[[1]]$in_id)
fold_rs$splits[[1]]$out_id
complement(fold_rs$splits[[1]])
```

### form_pred

#### Extract Predictor Names from Formula or Terms

**Description**

`all.vars` returns all variables used in a formula. This function only returns the variables explicitly used on the right-hand side (i.e., it will not resolve dots unless the object is `terms` with a data set specified).

**Usage**

```r
form_pred(object, ...)
```

**Arguments**

- `object`: A model formula or `stats::terms()` object.
- `...`: Arguments to pass to `all.vars()`

**Value**

A character vector of names

**Examples**

```r
form_pred(y ~ x + z)
form_pred(terms(y ~ x + z))

form_pred(y ~ x + log(z))
form_pred(log(y) ~ x + z)

form_pred(y1 + y2 ~ x + z)
form_pred(log(y1) + y2 ~ x + z)

# will fail:
# form_pred(y ~ .)

form_pred(terms(mpg ~ (.)^2, data = mtcars))
form_pred(terms(~ (.)^2, data = mtcars))
```
**group_bootstraps**

**Group Bootstraps**

**Description**

Group bootstrapping creates splits of the data based on some grouping variable (which may have more than a single row associated with it). A common use of this kind of resampling is when you have repeated measures of the same subject. A bootstrap sample is a sample that is the same size as the original data set that is made using replacement. This results in analysis samples that have multiple replicates of some of the original rows of the data. The assessment set is defined as the rows of the original data that were not included in the bootstrap sample. This is often referred to as the "out-of-bag" (OOB) sample.

**Usage**

```r
group_bootstraps(data, group, times = 25, apparent = FALSE, ...)
```

**Arguments**

- `data`: A data frame.
- `group`: A variable in `data` (single character or name) used for grouping observations with the same value to either the analysis or assessment set within a fold.
- `times`: The number of bootstrap samples.
- `apparent`: A logical. Should an extra resample be added where the analysis and holdout subset are the entire data set. This is required for some estimators used by the `summary` function that require the apparent error rate.
- `...`: Not currently used.

**Details**

The argument `apparent` enables the option of an additional "resample" where the analysis and assessment data sets are the same as the original data set. This can be required for some types of analysis of the bootstrap results.

**Value**

An tibble with classes `group_bootstraps`, `bootstraps`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and a column called `id` that has a character string with the resample identifier.

**Examples**

```r
data(ames, package = "modeldata")
set.seed(13)
group_bootstraps(ames, Neighborhood, times = 3)
```
group_mc_cv

```r
group_bootstraps(ames, Neighborhood, times = 3, apparent = TRUE)
```

---

**group_mc_cv**  
*Group Monte Carlo Cross-Validation*

**Description**

Group Monte Carlo cross-validation creates splits of the data based on some grouping variable (which may have more than a single row associated with it). One resample of Monte Carlo cross-validation takes a random sample (without replacement) of groups in the original data set to be used for analysis. All other data points are added to the assessment set. A common use of this kind of resampling is when you have repeated measures of the same subject.

**Usage**

```r
group_mc_cv(data, group, prop = 3/4, times = 25, ...)
```

**Arguments**

- **data**: A data frame.
- **group**: A variable in `data` (single character or name) used for grouping observations with the same value to either the analysis or assessment set within a fold.
- **prop**: The proportion of data to be retained for modeling/analysis.
- **times**: The number of times to repeat the sampling.
- ... Not currently used.

**Value**

A tibble with classes `group_mc_cv`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and an identification variable.

**Examples**

```r
data(ames, package = "modeldata")
set.seed(123)
group_mc_cv(ames, group = Neighborhood, times = 5)
```
Group V-Fold Cross-Validation

Description

Group V-fold cross-validation creates splits of the data based on some grouping variable (which may have more than a single row associated with it). The function can create as many splits as there are unique values of the grouping variable or it can create a smaller set of splits where more than one group is left out at a time. A common use of this kind of resampling is when you have repeated measures of the same subject.

Usage

```r
group_vfold_cv(
  data,
  group = NULL,
  v = NULL,
  repeats = 1,
  balance = c("groups", "observations"),
  ...
)
```

Arguments

- `data` A data frame.
- `group` A variable in `data` (single character or name) used for grouping observations with the same value to either the analysis or assessment set within a fold.
- `v` The number of partitions of the data set. If left as `NULL` (the default), `v` will be set to the number of unique values in the grouping variable, creating "leave-one-group-out" splits.
- `repeats` The number of times to repeat the V-fold partitioning.
- `balance` If `v` is less than the number of unique groups, how should groups be combined into folds? Should be one of "groups", which will assign roughly the same number of unique groups to each fold, or "observations", which will assign roughly the same number of observations to each fold.
- `...` Not currently used.

Value

A tibble with classes `group_vfold_cv`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and an identification variable.
Examples

data(ames, package = "modeldata")
set.seed(123)
group_vfold_cv(ames, group = Neighborhood, v = 5)
group_vfold_cv(ames,
  group = Neighborhood,
  v = 5,
  balance = "observations"
)
group_vfold_cv(ames, group = Neighborhood, v = 5, repeats = 2)

# Leave-one-group-out CV
group_vfold_cv(ames, group = Neighborhood)

initial_split

Simple Training/Test Set Splitting

Description

initial_split creates a single binary split of the data into a training set and testing set. initial_time_split does the same, but takes the first prop samples for training, instead of a random selection. group_initial_split creates splits of the data based on some grouping variable, so that all data in a "group" is assigned to the same split. training and testing are used to extract the resulting data.

Usage

initial_split(data, prop = 3/4, strata = NULL, breaks = 4, pool = 0.1, ...)
initial_time_split(data, prop = 3/4, lag = 0, ...)
training(x)
testing(x)
group_initial_split(data, group, prop = 3/4, ...)

Arguments

data A data frame.
prop The proportion of data to be retained for modeling/analysis.
strata A variable in data (single character or name) used to conduct stratified sampling. When not NULL, each resample is created within the stratification variable. Numeric strata are binned into quartiles.
breaks  A single number giving the number of bins desired to stratify a numeric stratification variable.

pool  A proportion of data used to determine if a particular group is too small and should be pooled into another group. We do not recommend decreasing this argument below its default of 0.1 because of the dangers of stratifying groups that are too small.

... Not currently used.

lag  A value to include a lag between the assessment and analysis set. This is useful if lagged predictors will be used during training and testing.

x  An rsplit object produced by initial_split() or initial_time_split().

group  A variable in data (single character or name) used for grouping observations with the same value to either the analysis or assessment set within a fold.

Details

With a strata argument, the random sampling is conducted within the stratification variable. This can help ensure that the resamples have equivalent proportions as the original data set. For a categorical variable, sampling is conducted separately within each class. For a numeric stratification variable, strata is binned into quartiles, which are then used to stratify. Strata below 10% of the total are pooled together; see make_strata() for more details.

Value

An rsplit object that can be used with the training and testing functions to extract the data in each split.

Examples

```r
set.seed(1353)
car_split <- initial_split(mtcars)
train_data <- training(car_split)
test_data <- testing(car_split)

data(drinks, package = "modeldata")
drinks_split <- initial_time_split(drinks)
train_data <- training(drinks_split)
test_data <- testing(drinks_split)
c(max(train_data$date), min(test_data$date)) # no lag

# With 12 period lag
drinks_lag_split <- initial_time_split(drinks, lag = 12)
train_data <- training(drinks_lag_split)
test_data <- testing(drinks_lag_split)
c(max(train_data$date), min(test_data$date)) # 12 period lag

set.seed(1353)
car_split <- group_initial_split(mtcars, cyl)
train_data <- training(car_split)
```
test_data <- testing(car_split)

int_pctl

### Bootstrap confidence intervals

#### Description
Calculate bootstrap confidence intervals using various methods.

#### Usage
- `int_pctl(.data, statistics, alpha = 0.05)`
- `int_t(.data, statistics, alpha = 0.05)`
- `int_bca(.data, statistics, alpha = 0.05, .fn, ...)`

#### Arguments
- `.data` A data frame containing the bootstrap resamples created using `bootstraps()`. For t- and BCA-intervals, the apparent argument should be set to `TRUE`. Even if the apparent argument is set to `TRUE` for the percentile method, the apparent data is never used in calculating the percentile confidence interval.
- `statistics` An unquoted column name or `dplyr` selector that identifies a single column in the data set containing the individual bootstrap estimates. This must be a list column of tidy tibbles (with columns `term` and `estimate`). For t-intervals, a standard tidy column (usually called `std.err`) is required. See the examples below.
- `alpha` Level of significance
- `.fn` A function to calculate statistic of interest. The function should take an `rsplit` as the first argument and the ... are required.
- `...` Arguments to pass to `.fn`.

#### Details
Percentile intervals are the standard method of obtaining confidence intervals but require thousands of resamples to be accurate. T-intervals may need fewer resamples but require a corresponding variance estimate. Bias-corrected and accelerated intervals require the original function that was used to create the statistics of interest and are computationally taxing.

#### Value
Each function returns a tibble with columns `.lower`, `.estimate`, `.upper`, `.alpha`, `.method`, and `.term`. `.method` is the type of interval (eg. "percentile", "student-t", or "BCa"). `.term` is the name of the estimate. Note the `.estimate` returned from `int_pctl()` is the mean of the estimates from the bootstrap resamples and not the estimate from the apparent model.

reg_intervals()

Examples

```r
library(broom)
library(dplyr)
library(purrr)
library(tibble)

lm_est <- function(split, ...) {
  lm(mpg ~ disp + hp, data = analysis(split)) %>%
  tidy()
}

set.seed(52156)
car_rs <-
  bootstraps(mtcars, 500, apparent = TRUE) %>%
  mutate(results = map(splits, lm_est))

int_pctl(car_rs, results)
int_t(car_rs, results)
int_bca(car_rs, results, .fn = lm_est)

# putting results into a tidy format
rank_corr <- function(split) {
  dat <- analysis(split)
  tibble(
    term = "corr",
    estimate = cor(dat$sqft, dat$price, method = "spearman"),
    # don't know the analytical std.err so no t-intervals
    std.err = NA_real_
  )
}

set.seed(69325)
data(Sacramento, package = "modeldata")
bootstraps(Sacramento, 1000, apparent = TRUE) %>%
  mutate(correlations = map(splits, rank_corr)) %>%
  int_pctl(correlations)
```
**labels.rset**  
*Find Labels from rset Object*

**Description**

Produce a vector of resampling labels (e.g. "Fold1") from an rset object. Currently, nested_cv is not supported.

**Usage**

```r
## S3 method for class 'rset'
labels(object, make_factor = FALSE, ...)

## S3 method for class 'vfold_cv'
labels(object, make_factor = FALSE, ...)
```

**Arguments**

- `object` An rset object
- `make_factor` A logical for whether the results should be a character or a factor.
- `...` Not currently used.

**Value**

A single character or factor vector.

**Examples**

```r
labels(vfold_cv(mtcars))
```

---

**labels.rsplit**  
*Find Labels from rsplit Object*

**Description**

Produce a tibble of identification variables so that single splits can be linked to a particular resample.

**Usage**

```r
## S3 method for class 'rsplit'
labels(object, ...)
```

**Arguments**

- `object` An rsplit object
- `...` Not currently used.
Value

A tibble.

See Also

add_resample_id

Examples

```r
cv_splits <- vfold_cv(mtcars)
labels(cv_splits$splits[[1]])
```

---

**Description**

Leave-one-out (LOO) cross-validation uses one data point in the original set as the assessment data and all other data points as the analysis set. A LOO resampling set has as many resamples as rows in the original data set.

**Usage**

```r
loo_cv(data, ...)
```

**Arguments**

- `data` A data frame.
- `...` Not currently used.

**Value**

An tibble with classes `loo_cv`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and one column called `id` that has a character string with the resample identifier.

**Examples**

```r
loo_cv(mtcars)
```
make_splits

Constructors for split objects

Description

Constructors for split objects

Usage

make_splits(x, ...)

## Default S3 method:
make_splits(x, ...)

## S3 method for class 'list'
make_splits(x, data, class = NULL, ...)

## S3 method for class 'data.frame'
make_splits(x, assessment, ...)

Arguments

x                  A list of integers with names "analysis" and "assessment", or a data frame of analysis or training data.
...
                    Further arguments passed to or from other methods (not currently used).
data
                    A data frame.
class
                    An optional class to give the object.
asessment
                    A data frame of assessment or testing data, which can be empty.

make_strata

Create or Modify Stratification Variables

Description

This function can create strata from numeric data and make non-numeric data more conducive for stratification.

Usage

make_strata(x, breaks = 4, nunique = 5, pool = 0.1, depth = 20)
Arguments

- **x**: An input vector.
- **breaks**: A single number giving the number of bins desired to stratify a numeric stratification variable.
- **nunique**: An integer for the number of unique value threshold in the algorithm.
- **pool**: A proportion of data used to determine if a particular group is too small and should be pooled into another group. We do not recommend decreasing this argument below its default of 0.1 because of the dangers of stratifying groups that are too small.
- **depth**: An integer that is used to determine the best number of percentiles that should be used. The number of bins are based on \( \min(5, \text{floor}(n / \text{depth})) \) where \( n = \text{length}(x) \). If \( x \) is numeric, there must be at least 40 rows in the data set (when depth = 20) to conduct stratified sampling.

Details

For numeric data, if the number of unique levels is less than **nunique**, the data are treated as categorical data.

For categorical inputs, the function will find levels of \( x \) than occur in the data with percentage less than **pool**. The values from these groups will be randomly assigned to the remaining strata (as will data points that have missing values in \( x \)).

For numeric data with more unique values than **nunique**, the data will be converted to being categorical based on percentiles of the data. The percentile groups will have no more than 20 percent of the data in each group. Again, missing values in \( x \) are randomly assigned to groups.

Value

- A factor vector.

Examples

```r
set.seed(61)
x1 <- rpois(100, lambda = 5)
table(x1)
table(make_strata(x1))

set.seed(554)
x2 <- rpois(100, lambda = 1)
table(x2)
table(make_strata(x2))

# small groups are randomly assigned
x3 <- factor(x2)
table(x3)
table(make_strata(x3))

# `oilType` data from `caret`
x4 <- rep(LETTERS[1:7], c(37, 26, 3, 7, 11, 10, 2))
```
# Manual resampling

---

### Description

`manual_rset()` is used for constructing the most minimal rset possible. It can be useful when you have custom rsplit objects built from `make_splits()`, or when you want to create a new rset from splits contained within an existing rset.

### Usage

```r
manual_rset(splits, ids)
```

### Arguments

- **splits**: A list of "rsplit" objects. It is easiest to create these using `make_splits()`.
- **ids**: A character vector of ids. The length of ids must be the same as the length of splits.

### Examples

```r
df <- data.frame(x = c(1, 2, 3, 4, 5, 6))

# Create an rset from custom indices
indices <- list(
  list(analys = c(1L, 2L), assessment = 3L),
  list(analys = c(4L, 5L), assessment = 6L)
)

splits <- lapply(indices, make_splits, data = df)

manual_rset(splits, c("Split 1", "Split 2"))
```

# You can also use this to create an rset from a subset of an existing rset
resamples <- vfold_cv(mtcars)
best_split <- resamples[5, ]
manual_rset(best_split$splits, best_split$id)

---

mc_cv

Monte Carlo Cross-Validation

Description

One resample of Monte Carlo cross-validation takes a random sample (without replacement) of the original data set to be used for analysis. All other data points are added to the assessment set.

Usage

mc_cv(data, prop = 3/4, times = 25, strata = NULL, breaks = 4, pool = 0.1, ...)

Arguments

data A data frame.
prop The proportion of data to be retained for modeling/analysis.
times The number of times to repeat the sampling.
strata A variable in data (single character or name) used to conduct stratified sampling. When not NULL, each resample is created within the stratification variable. Numeric strata are binned into quartiles.
breaks A single number giving the number of bins desired to stratify a numeric stratification variable.
pool A proportion of data used to determine if a particular group is too small and should be pooled into another group. We do not recommend decreasing this argument below its default of 0.1 because of the dangers of stratifying groups that are too small.
... Not currently used.

Details

With a strata argument, the random sampling is conducted within the stratification variable. This can help ensure that the resamples have equivalent proportions as the original data set. For a categorical variable, sampling is conducted separately within each class. For a numeric stratification variable, strata is binned into quartiles, which are then used to stratify. Strata below 10% of the total are pooled together; see make_strata() for more details.

Value

An tibble with classes mc_cv, rset, tbl_df, tbl, and data.frame. The results include a column for the data split objects and a column called id that has a character string with the resample identifier.
Examples

```r
mc_cv(mtcars, times = 2)
mc_cv(mtcars, prop = .5, times = 2)

library(purrr)
data(wa_churn, package = "modeldata")

set.seed(13)
resample1 <- mc_cv(wa_churn, times = 3, prop = .5)
map_dbl(resample1$splits,
    function(x) {
        dat <- as.data.frame(x)$churn
        mean(dat == "Yes")
    } )

set.seed(13)
resample2 <- mc_cv(wa_churn, strata = churn, times = 3, prop = .5)
map_dbl(resample2$splits,
    function(x) {
        dat <- as.data.frame(x)$churn
        mean(dat == "Yes")
    } )

set.seed(13)
resample3 <- mc_cv(wa_churn, strata = tenure, breaks = 6, times = 3, prop = .5)
map_dbl(resample3$splits,
    function(x) {
        dat <- as.data.frame(x)$churn
        mean(dat == "Yes")
    } )
```

---

**nested_cv**

**Nested or Double Resampling**

**Description**

`nested_cv` can be used to take the results of one resampling procedure and conduct further resamples within each split. Any type of resampling used in `rsample` can be used.

**Usage**

`nested_cv(data, outside, inside)`
**Arguments**

- `data`: A data frame.
- `outside`: The initial resampling specification. This can be an already created object or an expression of a new object (see the examples below). If the latter is used, the `data` argument does not need to be specified and, if it is given, will be ignored.
- `inside`: An expression for the type of resampling to be conducted within the initial procedure.

**Details**

It is a bad idea to use bootstrapping as the outer resampling procedure (see the example below)

**Value**

An tibble with `nested_cv` class and any other classes that outer resampling process normally contains. The results include a column for the outer data split objects, one or more id columns, and a column of nested tibbles called `inner_resamples` with the additional resamples.

**Examples**

```r
## Using expressions for the resampling procedures:
nested_cv(mtcars, outside = vfold_cv(v = 3), inside = bootstraps(times = 5))

## Using an existing object:
folds <- vfold_cv(mtcars)
nested_cv(mtcars, folds, inside = bootstraps(times = 5))

## The dangers of outer bootstraps:
set.seed(2222)
bad_idea <- nested_cv(mtcars, 
                      outside = bootstraps(times = 5), 
                      inside = vfold_cv(v = 3))

first_outer_split <- bad_idea$splits[[1]]
outer_analysis <- as.data.frame(first_outer_split)
sum(grepl("Volvo 142E", rownames(outer_analysis)))

## For the 3-fold CV used inside of each bootstrap, how are the replicated
## 'Volvo 142E' data partitioned?
first_inner_split <- bad_idea$inner_resamples[[1]]$splits[[1]]
inner_analysis <- as.data.frame(first_inner_split)
inner_assess <- as.data.frame(first_inner_split, data = "assessment")

sum(grepl("Volvo 142E", rownames(inner_analysis)))
sum(grepl("Volvo 142E", rownames(inner_assess)))
```
permutations

Description

A permutation sample is the same size as the original data set and is made by permuting/shuffling one or more columns. This results in analysis samples where some columns are in their original order and some columns are permuted to a random order. Unlike other sampling functions in rsample, there is no assessment set and calling assessment() on a permutation split will throw an error.

Usage

permutations(data, permute = NULL, times = 25, apparent = FALSE, ...)

Arguments

data A data frame.
permute One or more columns to shuffle. This argument supports tidyselect selectors. Multiple expressions can be combined with c(). Variable names can be used as if they were positions in the data frame, so expressions like x:y can be used to select a range of variables. See language for more details.
times The number of permutation samples.
apparent A logical. Should an extra resample be added where the analysis is the standard data set.
...

Details

The argument apparent enables the option of an additional "resample" where the analysis data set is the same as the original data set. Permutation-based resampling can be especially helpful for computing a statistic under the null hypothesis (e.g. t-statistic). This forms the basis of a permutation test, which computes a test statistic under all possible permutations of the data.

Value

A tibble with classes permutations, rset, tbl_df, tbl, and data.frame. The results include a column for the data split objects and a column called id that has a character string with the resample identifier.

Examples

permutations(mtcars, mpg, times = 2)
permutations(mtcars, mpg, times = 2, apparent = TRUE)

library(purrr)
resample1 <- permutations(mtcars, starts_with("c"), times = 1)
resample1$splits[[1]] %>% analysis()

resample2 <- permutations(mtcars, hp, times = 10, apparent = TRUE)
map_dbl(resample2$splits, function(x) {
  t.test(hp ~ vs, data = analysis(x))$statistic
})

---

**populate**

### Add Assessment Indices

**Description**

Many `rsplit` and `rset` objects do not contain indicators for the assessment samples. `populate()` can be used to fill the slot for the appropriate indices.

**Usage**

`populate(x, ...)`

**Arguments**

- **x**: A `rsplit` and `rset` object.
- **...**: Not currently used

**Value**

An object of the same kind with the integer indices.

**Examples**

```r
set.seed(28432)
fold_rs <- vfold_cv(mtcars)
fold_rs$splits[[1]]$out_id
complement(fold_rs$splits[[1]])

populate(fold_rs$splits[[1]])$out_id

fold_rs_all <- populate(fold_rs)
fold_rs_all$splits[[1]]$out_id
```
**reg_intervals**  
A convenience function for confidence intervals with linear-ish parametric models

**Description**
A convenience function for confidence intervals with linear-ish parametric models

**Usage**
```
reg_intervals(
  formula,  
data,  
model_fn = "lm",  
type = "student-t",  
times = NULL,  
alpha = 0.05,  
filter = term != "(Intercept)",  
keep_reps = FALSE,  
...
)
```

**Arguments**
- **formula**: An R model formula with one outcome and at least one predictor.
- **data**: A data frame.
- **model_fn**: The model to fit. Allowable values are "lm", "glm", "survreg", and "coxph". The latter two require that the survival package be installed.
- **type**: The type of bootstrap confidence interval. Values of "student-t" and "percentile" are allowed.
- **times**: A single integer for the number of bootstrap samples. If left NULL, 1,001 are used for t-intervals and 2,001 for percentile intervals.
- **alpha**: Level of significance.
- **filter**: A logical expression used to remove rows from the final result, or NULL to keep all rows.
- **keep_reps**: Should the individual parameter estimates for each bootstrap sample be retained?
- **...**: Options to pass to the model function (such as family for glm()).

**Value**
A tibble with columns "term", ".lower", ".estimate", ".upper", ".alpha", and ".method". If keep_reps = TRUE, an additional list column called ".replicates" is also returned.
**References**

*Bootstrap Confidence Intervals*, [https://rsample.tidymodels.org/articles/Applications/Intervals.html](https://rsample.tidymodels.org/articles/Applications/Intervals.html)

**See Also**

`int_pctl()`, `int_t()`

**Examples**

```r
set.seed(1)
reg_intervals(mpg ~ I(1 / sqrt(disp)), data = mtcars)

set.seed(1)
reg_intervals(mpg ~ I(1 / sqrt(disp)), data = mtcars, keep_reps = TRUE)
```

---

**reshuffle_rset**

"Reshuffle" an rset to re-generate a new rset with the same parameters

**Description**

This function re-generates an rset object, using the same arguments used to generate the original.

**Usage**

`reshuffle_rset(rset)`

**Arguments**

- `rset` The rset object to be reshuffled

**Value**

An rset of the same class as `rset`.

**Examples**

```r
set.seed(123)
(starting_splits <- group_vfold_cv(mtcars, cyl, v = 3))
reshuffle_rset(starting_splits)
```
reverse_splits

Reverse the analysis and assessment sets

Description

This function "swaps" the analysis and assessment sets of either a single rsplit or all rsplit in the splits column of an rset object.

Usage

reverse_splits(x, ...)

## Default S3 method:
reverse_splits(x, ...)

## S3 method for class 'permutations'
reverse_splits(x, ...)

## S3 method for class 'perm_split'
reverse_splits(x, ...)

## S3 method for class 'rsplit'
reverse_splits(x, ...)

## S3 method for class 'rset'
reverse_splits(x, ...)

Arguments

x

An rset or rsplit object.

... These dots are for future extensions and must be empty.

Value

An object of the same class as x

Examples

set.seed(123)
starting_splits <- vfold_cv(mtcars, v = 3)
reverse_splits(starting_splits)
reverse_splits(starting_splits$splits[[1]])
Description
This resampling method is useful when the data set has a strong time component. The resamples are not random and contain data points that are consecutive values. The function assumes that the original data set are sorted in time order.

Usage
```
rolling_origin(
  data,
  initial = 5,
  assess = 1,
  cumulative = TRUE,
  skip = 0,
  lag = 0,
  ...
)
```

Arguments
- `data`: A data frame.
- `initial`: The number of samples used for analysis/modeling in the initial resample.
- `assess`: The number of samples used for each assessment resample.
- `cumulative`: A logical. Should the analysis resample grow beyond the size specified by `initial` at each resample?.
- `skip`: A integer indicating how many (if any) additional resamples to skip to thin the total amount of data points in the analysis resample. See the example below.
- `lag`: A value to include a lag between the assessment and analysis set. This is useful if lagged predictors will be used during training and testing.
- `...`: Not currently used.

Details
The main options, `initial` and `assess`, control the number of data points from the original data that are in the analysis and assessment set, respectively. When `cumulative = TRUE`, the analysis set will grow as resampling continues while the assessment set size will always remain static. `skip` enables the function to not use every data point in the resamples. When `skip = 0`, the resampling data sets will increment by one position. Suppose that the rows of a data set are consecutive days. Using `skip = 5` will make the analysis data set to operate on `weeks` instead of days. The assessment set size is not affected by this option.
Value

An tibble with classes `rolling_origin`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and a column called `id` that has a character string with the resample identifier.

See Also

`sliding_window()`, `sliding_index()`, and `sliding_period()` for additional time based resampling functions.

Examples

```r
set.seed(1131)
ex_data <- data.frame(row = 1:20, some_var = rnorm(20))
dim(rolling_origin(ex_data))
dim(rolling_origin(ex_data, skip = 2))
dim(rolling_origin(ex_data, skip = 2, cumulative = FALSE))

# You can also roll over calendar periods by first nesting by that period,
# which is especially useful for irregular series where a fixed window
# is not useful. This example slides over 5 years at a time.
library(dplyr)
library(tidyr)
data(drinks, package = "modeldata")

drinks_annual <- drinks %>%
  mutate(year = as.POSIXlt(date)$year + 1900) %>%
  nest(data = c(-year))
multi_year_roll <- rolling_origin(drinks_annual, cumulative = FALSE)

analysis(multi_year_roll$splits[[1]])
assessment(multi_year_roll$splits[[1]])
```

---

**rsample-dplyr**

**Compatibility with dplyr**

**Description**

rsample should be fully compatible with dplyr 1.0.0.

With older versions of dplyr, there is partial support for the following verbs: `mutate()`, `arrange()`, `filter()`, `rename()`, `select()`, and `slice()`. We strongly recommend updating to dplyr 1.0.0 if possible to get more complete integration with dplyr.
**Version Specific Behavior**

rsample performs somewhat differently depending on whether you have dplyr >= 1.0.0 (new) or dplyr < 1.0.0 (old). Additionally, version 0.0.7 of rsample (new) introduced some changes to how rsample objects work with dplyr, even on old dplyr. Most of these changes influence the return value of a dplyr verb and determine whether it will be a tibble or an rsample rset subclass.

The table below attempts to capture most of these changes. These examples are not exhaustive and may not capture some edge-cases.

### Joins:
The following affect all of the dplyr joins, such as `left_join()`, `right_join()`, `full_join()`, and `inner_join()`.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Old Rsample + Old Dplyr</th>
<th>New Rsample + Old Dplyr</th>
<th>New Rsample + New Dplyr</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>join(rset, tbl)</code></td>
<td>error</td>
<td>error</td>
<td>tibble</td>
</tr>
</tbody>
</table>

The idea here is that, if there are less rows in the result, the result should not be an rset object. For example, you can’t have a 10-fold CV object without 10 rows.

### Joins that keep the rows of the original rset object:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Old Rsample + Old Dplyr</th>
<th>New Rsample + Old Dplyr</th>
<th>New Rsample + New Dplyr</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>join(rset, tbl)</code></td>
<td>error</td>
<td>error</td>
<td>rset</td>
</tr>
</tbody>
</table>

As with the logic above, if the original rset object (defined by the split column and the id column(s)) is left intact, the results should be an rset.

### Row Subsetting:
As mentioned above, this should result in a tibble if any rows are removed or added. Simply reordering rows still results in a valid rset with new rsample.

### Cases where rows are removed or added:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Old Rsample + Old Dplyr</th>
<th>New Rsample + Old Dplyr</th>
<th>New Rsample + New Dplyr</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rset[inds,]</code></td>
<td>tibble</td>
<td>tibble</td>
<td>tibble</td>
</tr>
<tr>
<td><code>slice(rset)</code></td>
<td>rset</td>
<td>tibble</td>
<td>tibble</td>
</tr>
<tr>
<td><code>filter(rset)</code></td>
<td>rset</td>
<td>tibble</td>
<td>tibble</td>
</tr>
</tbody>
</table>

### Cases where all rows are kept, but are possibly reordered:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Old Rsample + Old Dplyr</th>
<th>New Rsample + Old Dplyr</th>
<th>New Rsample + New Dplyr</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rset[inds,]</code></td>
<td>tibble</td>
<td>rset</td>
<td>rset</td>
</tr>
<tr>
<td><code>slice(rset)</code></td>
<td>rset</td>
<td>rset</td>
<td>rset</td>
</tr>
<tr>
<td><code>filter(rset)</code></td>
<td>rset</td>
<td>rset</td>
<td>rset</td>
</tr>
<tr>
<td><code>arrange(rset)</code></td>
<td>rset</td>
<td>rset</td>
<td>rset</td>
</tr>
</tbody>
</table>
Column Subsetting:
When the splits column or any id columns are dropped or renamed, the result should no longer be considered a valid rset.

Cases when the required columns are removed or renamed:

<table>
<thead>
<tr>
<th>operation</th>
<th>old rsample + old dplyr</th>
<th>new rsample + old dplyr</th>
<th>new rsample + new dplyr</th>
</tr>
</thead>
<tbody>
<tr>
<td>rset[,ind]</td>
<td>tibble</td>
<td>tibble</td>
<td>tibble</td>
</tr>
<tr>
<td>select(rset)</td>
<td>rset</td>
<td>tibble</td>
<td>tibble</td>
</tr>
<tr>
<td>rename(rset)</td>
<td>tibble</td>
<td>tibble</td>
<td>tibble</td>
</tr>
</tbody>
</table>

Cases when no required columns are affected:

<table>
<thead>
<tr>
<th>operation</th>
<th>old rsample + old dplyr</th>
<th>new rsample + old dplyr</th>
<th>new rsample + new dplyr</th>
</tr>
</thead>
<tbody>
<tr>
<td>rset[,ind]</td>
<td>tibble</td>
<td>rset</td>
<td>rset</td>
</tr>
<tr>
<td>select(rset)</td>
<td>rset</td>
<td>rset</td>
<td>rset</td>
</tr>
<tr>
<td>rename(rset)</td>
<td>rset</td>
<td>rset</td>
<td>rset</td>
</tr>
</tbody>
</table>

Other Column Operations:

Cases when the required columns are altered:

<table>
<thead>
<tr>
<th>operation</th>
<th>old rsample + old dplyr</th>
<th>new rsample + old dplyr</th>
<th>new rsample + new dplyr</th>
</tr>
</thead>
<tbody>
<tr>
<td>mutate(rset)</td>
<td>rset</td>
<td>tibble</td>
<td>tibble</td>
</tr>
</tbody>
</table>

Cases when no required columns are affected:

<table>
<thead>
<tr>
<th>operation</th>
<th>old rsample + old dplyr</th>
<th>new rsample + old dplyr</th>
<th>new rsample + new dplyr</th>
</tr>
</thead>
<tbody>
<tr>
<td>mutate(rset)</td>
<td>rset</td>
<td>rset</td>
<td>rset</td>
</tr>
</tbody>
</table>

rsample2caret

Convert Resampling Objects to Other Formats

Description
These functions can convert resampling objects between rsample and caret.

Usage
rsample2caret(object, data = c("analysis", "assessment"))
caret2rsample(ctrl, data = NULL)
Arguments

object  An rset object. Currently, nested_cv is not supported.
data  The data that was originally used to produce the ctrl object.
ctrl  An object produced by trainControl that has had the index and indexOut elements populated by integers. One method of getting this is to extract the control objects from an object produced by train.

Value

rsample2caret returns a list that mimics the index and indexOut elements of a trainControl object. caret2rsample returns an rset object of the appropriate class.

rset_reconstruct  Extending rsample with new rset subclasses

Description

rset_reconstruct() encapsulates the logic for allowing new rset subclasses to work properly with vctrs (through vctrs::vec_restore()) and dplyr (through dplyr::dplyr_reconstruct()). It is intended to be a developer tool, and is not required for normal usage of rsample.

Usage

rset_reconstruct(x, to)

Arguments

x  A data frame to restore to an rset subclass.
to  An rset subclass to restore to.

Details

rset objects are considered "reconstructable" after a vctrs/dplyr operation if:

- x and to both have an identical column named "splits" (column and row order do not matter).
- x and to both have identical columns prefixed with "id" (column and row order do not matter).

Value

x restored to the rset subclass of to.
Examples

to <- bootstraps(mtcars, times = 25)

# Imitate a vctrs/dplyr operation,
# where the class might be lost along the way
x <- tibble::as_tibble(to)

# Say we added a new column to `x`. Here we mock a `mutate()`.
x$foo <- "bar"

# This is still reconstructable to `to`
rset_reconstruct(x, to)

# Say we lose the first row
x <- x[-1,]

# This is no longer reconstructable to `to`, as `x` is no longer an rset
# bootstraps object with 25 bootstraps if one is lost!
rset_reconstruct(x, to)

Description

These resampling functions are focused on various forms of time series resampling.

- **sliding_window()** uses the row number when computing the resampling indices. It is independent of any time index, but is useful with completely regular series.
- **sliding_index()** computes resampling indices relative to the index column. This is often a Date or POSIXct column, but doesn’t have to be. This is useful when resampling irregular series, or for using irregular lookback periods such as `lookback = lubridate::years(1)` with daily data (where the number of days in a year may vary).
- **sliding_period()** first breaks up the index into less granular groups based on period, and then uses that to construct the resampling indices. This is extremely useful for constructing rolling monthly or yearly windows from daily data.

Usage

```
sliding_window(
  data,
  ..., 
  lookback = 0L,
  assess_start = 1L,
  assess_stop = 1L,
  complete = TRUE,
  step = 1L,
  skip = 0L
)```

sliding_index(
  data,
  index,
  ...,  
  lookback = 0L,
  assess_start = 1L,
  assess_stop = 1L,
  complete = TRUE,
  step = 1L,
  skip = 0L
)

sliding_period(
  data,
  index,
  period,
  ..., 
  lookback = 0L,
  assess_start = 1L,
  assess_stop = 1L,
  complete = TRUE,
  step = 1L,
  skip = 0L,
  every = 1L,
  origin = NULL
)

**Arguments**

- **data**
  - A data frame.

- **...**
  - These dots are for future extensions and must be empty.

- **lookback**
  - The number of elements to look back from the current element when computing the resampling indices of the analysis set. The current row is always included in the analysis set.

  - For **sliding_window()**, a single integer defining the number of rows to look back from the current row.
  - For **sliding_index()**, a single object that will be subtracted from the `index` as `index - lookback` to define the boundary of where to start searching for rows to include in the current resample. This is often an integer value corresponding to the number of days to look back, or a lubridate `Period` object.
  - For **sliding_period()**, a single integer defining the number of groups to look back from the current group, where the groups were defined from breaking up the index according to the `period`.

  - In all cases, `Inf` is also allowed to force an expanding window.
assess_start, assess_stop

This combination of arguments determines how far into the future to look when constructing the assessment set. Together they construct a range of \([\text{index} + \text{assess_start}, \text{index} + \text{assess_stop}]\) to search for rows to include in the assessment set.

Generally, assess_start will always be 1 to indicate that the first value to potentially include in the assessment set should start one element after the current row, but it can be increased to a larger value to create "gaps" between the analysis and assessment set if you are worried about high levels of correlation in short term forecasting.

- For `sliding_window()`, these are both single integers defining the number of rows to look forward from the current row.
- For `sliding_index()`, these are single objects that will be added to the index to compute the range to search for rows to include in the assessment set. This is often an integer value corresponding to the number of days to look forward, or a lubridate Period object.
- For `sliding_period()`, these are both single integers defining the number of groups to look forward from the current group, where the groups were defined from breaking up the index according to the period.

complete

A single logical. When using lookback to compute the analysis sets, should only complete windows be considered? If set to `FALSE`, partial windows will be used until it is possible to create a complete window (based on lookback). This is a way to use an expanding window up to a certain point, and then switch to a sliding window.

step

A single positive integer. After computing the resampling indices, step is used to thin out the results by selecting every step-th result by subsetting the indices with `seq(1L, n_indices, by = step)`. step is applied after skip. Note that step is independent of any time index used.

skip

A single positive integer, or zero. After computing the resampling indices, the first skip results will be dropped by subsetting the indices with `seq(skip + 1L, n_indices)`. This can be especially useful when combined with lookback = Inf, which creates an expanding window starting from the first row. By skipping forward, you can drop the first few windows that have very few data points. skip is applied before step. Note that skip is independent of any time index used.

index

The index to compute resampling indices relative to, specified as a bare column name. This must be an existing column in data.

- For `sliding_index()`, this is commonly a date vector, but is not required.
- For `sliding_period()`, it is required that this is a Date or POSIXct vector.

The index must be an increasing vector, but duplicate values are allowed. Additionally, the index cannot contain any missing values.

period

The period to group the index by. This is specified as a single string, such as "year" or "month". See the .period argument of `slider::slide_period()` for the full list of options and further explanation.

ever

A single positive integer. The number of periods to group together.

For example, if the period was set to "year" with an every value of 2, then the years 1970 and 1971 would be placed in the same group.
The reference date time value. The default when left as NULL is the epoch time of 1970-01-01 00:00:00, in the time zone of the index.
This is generally used to define the anchor time to count from, which is relevant when the every value is > 1.

See Also
- `rolling_origin()`
- `slider::slide()`, `slider::slide_index()`, and `slider::slide_period()`, which power these resamplers.

Examples

```r
library(vctrs)
library(tibble)
library(modeldata)
data("Chicago")

index <- new_date(c(1, 3, 4, 7, 8, 9, 13, 15, 16, 17))
df <- tibble(x = 1:10, index = index)
df

# Look back two rows beyond the current row, for a total of three rows
# in each analysis set. Each assessment set is composed of the two rows after
# the current row.
sliding_window(df, lookback = 2, assess_stop = 2)

# Same as before, but step forward by 3 rows between each resampling slice,
# rather than just by 1.
rset <- sliding_window(df, lookback = 2, assess_stop = 2, step = 3)
rset

analysis(rset$splits[[1]])
analysis(rset$splits[[2]])

# Now slide relative to the `index` column in `df`. This time we look back
# 2 days from the current row's `index` value, and 2 days forward from
# it to construct the assessment set. Note that this series is irregular,
# so it produces different results than `sliding_window()`. Additionally,
# note that it is entirely possible for the assessment set to contain no
# data if you have a highly irregular series and "look forward" into a
# date range where no data points actually exist!
sliding_index(df, index, lookback = 2, assess_stop = 2)

# With `sliding_period()`, we can break up our date index into less granular
# chunks, and slide over them instead of the index directly. Here we'll use
# the Chicago data, which contains daily data spanning 16 years, and we'll
# break it up into rolling yearly chunks. Three years worth of data will
# be used for the analysis set, and one years worth of data will be held out
# for performance assessment.
sliding_period(}
tidy.rspli

Chicago,
date,
"year",
lookback = 2,
assess_stop = 1
)

# Because `lookback = 2`, three years are required to form a "complete"
# window of data. To allow partial windows, set `complete = FALSE`.
# Here that first constructs two expanding windows until a complete three
# year window can be formed, at which point we switch to a sliding window.
sliding_period(
    Chicago,
date,
    "year",
    lookback = 2,
    assess_stop = 1,
    complete = FALSE
)

# Alternatively, you could break the resamples up by month. Here we'll
# use an expanding monthly window by setting `lookback = Inf`, and each
# assessment set will contain two months of data. To ensure that we have
# enough data to fit our models, we'll `skip` the first 4 expanding windows.
# Finally, to thin out the results, we'll `step` forward by 2 between
# each resample.
sliding_period(

tidy.rspli

**Tidy Resampling Object**

**Description**

The tidy function from the **broom** package can be used on `rset` and `rsplit` objects to generate

tibbles with which rows are in the analysis and assessment sets.

**Usage**

```r
## S3 method for class 'rsplit'
tidy(x, unique_ind = TRUE, ...)
```
## S3 method for class 'rset'
tidy(x, ...)

## S3 method for class 'vfold_cv'
tidy(x, ...)

## S3 method for class 'nested_cv'
tidy(x, ...)

### Arguments

- **x**
  - A rset or rsplit object

- **unique_ind**
  - Should unique row identifiers be returned? For example, if FALSE then bootstrapping results will include multiple rows in the sample for the same row in the original data.

- **...**
  - Not currently used.

### Details

Note that for nested resampling, the rows of the inner resample, named `inner_Row`, are relative row indices and do not correspond to the rows in the original data set.

### Value

A tibble with columns `Row` and `Data`. The latter has possible values "Analysis" or "Assessment". For rset inputs, identification columns are also returned but their names and values depend on the type of resampling. vfold_cv contains a column "Fold" and, if repeats are used, another called "Repeats". bootstraps and mc_cv use the column "Resample".

### Examples

```r
library(ggplot2)
theme_set(theme_bw())
set.seed(4121)
cv <- tidy(vfold_cv(mtcars, v = 5))
ggplot(cv, aes(x = Fold, y = Row, fill = Data)) +
  geom_tile() +
  scale_fill_brewer()

set.seed(4121)
rcv <- tidy(vfold_cv(mtcars, v = 5, repeats = 2))
ggplot(rcv, aes(x = Fold, y = Row, fill = Data)) +
  geom_tile() +
  facet_wrap(~Repeat) +
  scale_fill_brewer()

set.seed(4121)
mccv <- tidy(mc_cv(mtcars, times = 5))
```
validation_split

Create a Validation Set

Description

validation_split() takes a single random sample (without replacement) of the original data set to be used for analysis. All other data points are added to the assessment set (to be used as the validation set). validation_time_split() does the same, but takes the first prop samples for training, instead of a random selection. group_validation_split() creates splits of the data based on some grouping variable, so that all data in a “group” is assigned to the same split.

Usage

validation_split(data, prop = 3/4, strata = NULL, breaks = 4, pool = 0.1, ...)

validation_time_split(data, prop = 3/4, lag = 0, ...)

group_validation_split(data, group, prop = 3/4, ...)

Arguments

data A data frame.

prop The proportion of data to be retained for modeling/analysis.

strata A variable in data (single character or name) used to conduct stratified sampling. When not NULL, each resample is created within the stratification variable. Numeric strata are binned into quartiles.
breaks: A single number giving the number of bins desired to stratify a numeric stratification variable.

pool: A proportion of data used to determine if a particular group is too small and should be pooled into another group. We do not recommend decreasing this argument below its default of 0.1 because of the dangers of stratifying groups that are too small.

... Not currently used.

lag: A value to include a lag between the assessment and analysis set. This is useful if lagged predictors will be used during training and testing.

group: A variable in `data` (single character or name) used for grouping observations with the same value to either the analysis or assessment set within a fold.

Details

With a `strata` argument, the random sampling is conducted within the stratification variable. This can help ensure that the resamples have equivalent proportions as the original data set. For a categorical variable, sampling is conducted separately within each class. For a numeric stratification variable, `strata` is binned into quartiles, which are then used to stratify. Strata below 10% of the total are pooled together; see `make_strata()` for more details.

Value

An tibble with classes `validation_split`, `rset`, `tbl_df`, `tbl`, and `data.frame`. The results include a column for the data split objects and a column called `id` that has a character string with the resample identifier.

Examples

```r
validation_split(mtcars, prop = .9)
data(drinks, package = "modeldata")validation_time_split(drinks)group_validation_split(mtcars, cyl)
```

---

### Vfold_cv

<table>
<thead>
<tr>
<th>vfold_cv</th>
<th>V-Fold Cross-Validation</th>
</tr>
</thead>
</table>

Description

V-fold cross-validation (also known as k-fold cross-validation) randomly splits the data into V groups of roughly equal size (called "folds"). A resample of the analysis data consists of V-1 of the folds while the assessment set contains the final fold. In basic V-fold cross-validation (i.e. no repeats), the number of resamples is equal to V.
Usage

vfold_cv(data, v = 10, repeats = 1, strata = NULL, breaks = 4, pool = 0.1, ...)

Arguments

data  A data frame.

v    The number of partitions of the data set.

repeats  The number of times to repeat the V-fold partitioning.

strata  A variable in data (single character or name) used to conduct stratified sampling. When not NULL, each resample is created within the stratification variable. Numeric strata are binned into quartiles.

breaks  A single number giving the number of bins desired to stratify a numeric stratification variable.

pool  A proportion of data used to determine if a particular group is too small and should be pooled into another group. We do not recommend decreasing this argument below its default of 0.1 because of the dangers of stratifying groups that are too small.

...  Not currently used.

Details

With more than one repeat, the basic V-fold cross-validation is conducted each time. For example, if three repeats are used with v = 10, there are a total of 30 splits: three groups of 10 that are generated separately.

With a strata argument, the random sampling is conducted within the stratification variable. This can help ensure that the resamples have equivalent proportions as the original data set. For a categorical variable, sampling is conducted separately within each class. For a numeric stratification variable, strata is binned into quartiles, which are then used to stratify. Strata below 10% of the total are pooled together; see make_strata() for more details.

Value

A tibble with classes vfold_cv, rset, tbl_df, tbl, and data.frame. The results include a column for the data split objects and one or more identification variables. For a single repeat, there will be one column called id that has a character string with the fold identifier. For repeats, id is the repeat number and an additional column called id2 that contains the fold information (within repeat).

Examples

vfold_cv(mtcars, v = 10)
vfold_cv(mtcars, v = 10, repeats = 2)

library(purrr)
data(wa_churn, package = "modeldata")

set.seed(13)
folds1 <- vfold_cv(wa_churn, v = 5)
map_dbl(folds1$splits, function(x) {
  dat <- as.data.frame(x)$churn
  mean(dat == "Yes")
})

set.seed(13)
folds2 <- vfold_cv(wa_churn, strata = churn, v = 5)
map_dbl(folds2$splits, function(x) {
  dat <- as.data.frame(x)$churn
  mean(dat == "Yes")
})

set.seed(13)
folds3 <- vfold_cv(wa_churn, strata = tenure, breaks = 6, v = 5)
map_dbl(folds3$splits, function(x) {
  dat <- as.data.frame(x)$churn
  mean(dat == "Yes")
})
