Package ‘rstan’

March 5, 2024

Type Package

Title R Interface to Stan

Version 2.32.6

Description User-facing R functions are provided to parse, compile, test, estimate, and analyze Stan models by accessing the header-only Stan library provided by the ‘StanHeaders’ package. The Stan project develops a probabilistic programming language that implements full Bayesian statistical inference via Markov Chain Monte Carlo, rough Bayesian inference via ‘variational’ approximation, and (optionally penalized) maximum likelihood estimation via optimization. In all three cases, automatic differentiation is used to quickly and accurately evaluate gradients without burdening the user with the need to derive the partial derivatives.

License GPL (>= 3)

NeedsCompilation yes

Imports methods, stats4, inline (>= 0.3.19), gridExtra (>= 2.3), Rcpp (>= 1.0.7), RcppParallel (>= 5.1.4), loo (>= 2.4.1), pkgbuild (>= 1.2.0), QuickJSR, ggplot2 (>= 3.3.5)

Depends R (>= 3.4.0), StanHeaders (>= 2.32.0)

LinkingTo Rcpp (>= 1.0.7), RcppEigen (>= 0.3.4.0.0), BH (>= 1.75.0-0), StanHeaders (>= 2.32.0), RcppParallel (>= 5.1.4)

Suggests testthat (>= 3.0.4), parallel, KernSmooth, shinystan, bayesplot, rmarkdown, rstantools, rstudioapi, Matrix, knitr, coda, V8

RStan is the R interface to the Stan C++ package. The RStan interface (rstan R package) provides:

- Full Bayesian inference using the No-U-Turn sampler (NUTS), a variant of Hamiltonian Monte Carlo (HMC)
- Approximate Bayesian inference using automatic differentiation variational inference (ADVI)
- Penalized maximum likelihood estimation using L-BFGS optimization

For documentation on Stan itself, including the manual and user guide for the modeling language, case studies and worked examples, and other tutorial information visit the Users section of the Stan website:

Examples

```r
## Not run:

stanmodelcode <- "
data {
  int<lower=0> N;
  array[N] real y;
}

parameters {
  real mu;
}

model {
  target += normal_lpdf(mu | 0, 10);
  target += normal_lpdf(y | mu, 1);
}
"

y <- rnorm(20)
dat <- list(N = 20, y = y);
```
fit <- stan(model_code = stanmodelcode, model_name = "example",
data = dat, iter = 2012, chains = 3, verbose = TRUE,
sample_file = file.path(tempdir(), 'norm.csv'))
print(fit)

# extract samples
e <- extract(fit, permuted = FALSE) # return a list of arrays
str(e)

arr <- as.array(fit) # return an array
str(arr)

mat <- as.matrix(fit) # return a matrix
str(mat)

## End(Not run)

---

as.array Create array, matrix, or data.frame objects from samples in a stanfit object

Description

The samples (without warmup) included in a stanfit object can be coerced to an array, matrix, or data.frame. Methods are also provided for checking and setting names and dimnames.

Usage

## S3 method for class 'stanfit'
as.array(x, ...)
## S3 method for class 'stanfit'
as.matrix(x, ...)
## S3 method for class 'stanfit'
as.data.frame(x, ...)
## S3 method for class 'stanfit'
is.array(x)
## S3 method for class 'stanfit'
dim(x)
## S3 method for class 'stanfit'
dimnames(x)
## S3 method for class 'stanfit'
names(x)
## S3 replacement method for class 'stanfit'
names(x) <- value

Arguments

x An object of S4 class stanfit.
Additional parameters that can be passed to `extract` for extracting samples from `x`. For now, `pars` is the only additional parameter supported.

For the names replacement method, a character vector to set/replace the parameter names in `x`.

Details

`as.array` and `as.matrix` can be applied to a `stanfit` object to coerce the samples without warmup to array or matrix. The `as.data.frame` method first calls `as.matrix` and then coerces this matrix to a `data.frame`.

The array has three named dimensions: iterations, chains, parameters. For `as.matrix`, all chains are combined, leaving a matrix of iterations by parameters.

Value

`as.array`, `as.matrix`, and `as.data.frame` return an array, matrix, and data.frame, respectively. `dim` and `dimnames` return the dim and dimnames of the array object that could be created, while `names` returns the third element of the dimnames, which are the names of the margins of the posterior distribution. The names assignment method allows for assigning more interpretable names to them.

`is.array` returns `TRUE` for `stanfit` objects that include samples; otherwise `FALSE`.

When the `stanfit` object does not contain samples, empty objects are returned from `as.array`, `as.matrix`, `as.data.frame`, `dim`, `dimnames`, and `names`.

See Also

S4 class `stanfit` and its method `extract`

Examples

```r
## Not run:
ex_model_code <- ' parameters { 
  array[2, 3] real alpha;
  array[2] real beta;
}
model { 
  for (i in 1:2) for (j in 1:3) 
    alpha[i, j] ~ normal(0, 1); 
  for (i in 1:2) 
    beta[i] ~ normal(0, 2); 
  # beta ~ normal(0, 2) // vectorized version
}

## fit the model
fit <- stan(model_code = ex_model_code, chains = 4)

dim(fit)
dimnames(fit)
is.array(fit)
```
a <- as.array(fit)
m <- as.matrix(fit)
d <- as.data.frame(fit)

## End(Not run)

As.mcmc.list

Create an mcmc.list from a stanfit object

Description

Create an mcmc.list (coda) from a stanfit object.

Usage

As.mcmc.list(object, pars, include = TRUE, ...)

Arguments

object object of class "stanfit"
pars optional character vector of parameters to include
include logical scalar indicating whether to include (the default) or exclude the parameters named in pars
... unused

Value

An object of class mcmc.list.

check_hmc_diagnostics

Check HMC diagnostics after sampling

Description

These functions print summaries of important HMC diagnostics or extract those diagnostics from a stanfit object. See the Details section, below.
Usage

check_hmc_diagnostics(object)
check_divergences(object)
check_treedepth(object)
check_energy(object)

get_divergent_iterations(object)
get_max_treedepth_iterations(object)
get_num_leapfrog_per_iteration(object)

get_num_divergent(object)
get_num_max_treedepth(object)

get_bfmi(object)
get_low_bfmi_chains(object)

Arguments

object A stanfit object.

Details

The check_hmc_diagnostics function calls the other check_* functions internally and prints an overall summary, but the other functions can also be called directly:

- check_divergences prints the number (and percentage) of iterations that ended with a divergence,
- check_treedepth prints the number (and percentage) of iterations that saturated the max treedepth,
- check_energy prints E-BFMI values for each chain for which E-BFMI is less than 0.2.

The get_* functions are for programmatic access to the diagnostics.

- get_divergent_iterations and get_max_treedepth_iterations return a logical vector indicating problems for individual iterations,
- get_num_divergent and get_num_max_treedepth return the number of offending iterations,
- get_num_leapfrog_per_iteration returns an integer vector with the number of leapfrog evaluations for each iteration,
- get_bfmi returns per-chain E-BFMI values and get_low_bfmi_chains returns the indices of chains with low E-BFMI.

The following are several of many resources that provide more information on these diagnostics:

- Brief explanations of some of the problems detected by these diagnostics can be found in the Brief Guide to Stan’s Warnings.
- Betancourt (2017) provides much more depth on these diagnostics as well as a conceptual introduction to Hamiltonian Monte Carlo in general.
 Gabry et al. (2018) and the bayesplot package vignettes demonstrate various visualizations of these diagnostics that can be made in R.

Examples

## Not run:
schools <- stan_demo("eight_schools")
check_hmc_diagnostics(schools)
check_divergences(schools)
check_treedepth(schools)
check_energy(schools)
## End(Not run)

### Diagnostic plots

#### RStan Diagnostic plots

**Description**

Diagnostic plots for HMC and NUTS using ggplot2.

**Usage**

```
stan_diag(object, 
  information = c("sample","stepsize", "treedepth","divergence"), 
  chain = 0, ...)
stan_par(object, par, chain = 0, ...)
stan_rhat(object, pars, ...)
stan_ess(object, pars, ...)
stan_mcse(object, pars, ...)
```

**Arguments**

- `object` A stanfit or stanreg object.
- `information` The information to be contained in the diagnostic plot.
Diagnostic plots

par, pars  The name of a single scalar parameter (par) or one or more parameter names (pars).

chain  If chain=0 (the default) all chains are combined. Otherwise the plot for chain is overlaid on the plot for all chains combined.

...  For stan_diag and stan_par, optional arguments to arrangeGrob. For stan_rhat, stan_ess, and stan_mcse, optional arguments to stat_bin in the ggplot2 package.

Details

stan_rhat, stan_ess, stan_mcse  Respectively, these plots show the distribution of the Rhat statistic, the ratio of effective sample size to total sample size, and the ratio of Monte Carlo standard error to posterior standard deviation for the estimated parameters. These plots are not intended to identify individual parameters, but rather to allow for quickly identifying if the estimated values of these quantities are desirable for all parameters.

stan_par  Calling stan_par generates three plots: (i) a scatterplot of par vs. the accumulated log-posterior (lp__), (ii) a scatterplot of par vs. the average Metropolis acceptance rate (accept_stat), and (iii) a violin plot showing the distribution of par at each of the sampled step sizes (one per chain). For the scatterplots, red points are superimposed to indicate which (if any) iterations encountered a divergent transition. Yellow points indicate a transition that hit the maximum treedepth rather than terminated its evolution normally.

stan_diag  The information argument is used to specify which plots stan_diag should generate:

- information='sample' Histograms of lp__ and accept_stat, as well as a scatterplot showing their joint distribution.
- information='stepsize' Violin plots showing the distributions of lp__ and accept_stat at each of the sampled step sizes (one per chain).
- information='treedepth' Histogram of treedepth and violin plots showing the distributions of lp__ and accept_stat for each value of treedepth.
- information='divergence' Violin plots showing the distributions of lp__ and accept_stat for iterations that encountered divergent transitions (divergent=1) and those that did not (divergent=0).

Value

For stan_diag and stan_par, a list containing the ggplot objects for each of the displayed plots. For stan_rhat, stan_ess, and stan_mcse, a single ggplot object.

Examples

## Not run:
fit <- stan_demo("eight_schools")

stan_diag(fit, info = 'sample') # shows three plots together
samp_info <- stan_diag(fit, info = 'sample') # saves the three plots in a list
samp_info[[3]] # access just the third plot

stan_diag(fit, info = 'sample', chain = 1) # overlay chain 1

stan_par(fit, par = "mu")

## End(Not run)

expose_stan_functions  Expose user-defined Stan functions to R for testing and simulation

Description

The Stan modeling language allows users to define their own functions in a functions block at the
top of a Stan program. The expose_stan_functions utility function uses sourceCpp to export	hose user-defined functions to the specified environment for testing inside R or for doing posterior
predictive simulations in R rather than in the generated quantities block of a Stan program.

Usage

expose_stan_functions(stanmodel, includes = NULL,
  show_compiler_warnings = FALSE, ...)
get_rng(seed = 0L)
get_stream()

Arguments

stanmodel  A stanmodel object, a stanfit object, a list produced by stanc or the path to
a Stan program (.stan file). In any of these cases, the underlying Stan program
should contain a non-empty functions block.

includes  If not NULL (the default), then a character vector of length one (possibly contain-
ing one or more "\n") of the form '#include "full/path/to/my_header.hpp"',
which will be inserted into the C++ code in the model's namespace and can
be used to provide definitions of functions that are declared but not defined in
stanmodel

show_compiler_warnings  Logical scalar defaulting to FALSE that controls whether compiler warnings,
which can be numerous and have never been relevant, are shown

seed  An integer vector of length one indicating the state of Stan's pseudo-random
number generator

...  Further arguments passed to sourceCpp.
Details

The `expose_stan_functions` function requires as much compliance with the C++14 standard as is implemented in the RTools toolchain for Windows. On Windows, you will likely need to specify `CXX14 = g++ -std=c++1y` in the file whose path is `normalizePath("~/R/Makevars")` in order for `expose_stan_functions` to work. Outside of Windows, the necessary compiler flags are set programatically, which is likely to suffice.

There are a few special types of user-defined Stan functions for which some additional details are relevant:

(P)RNG functions: If a user-defined Stan function ends in `_rng`, then it can use the Boost pseudo-random number generator used by Stan. When exposing such functions to R, `base_rng__` and `pstream__` arguments will be added to the `formals`. The `base_rng__` argument should be passed the result of a call to `get_rng` (perhaps specifying its `seed` argument for reproducibility) and the `pstream__` should be passed the result of a call to `get_stream`, which can be used to see the result of `print` and `reject` calls in the user-defined Stan functions. These arguments default to `get_stream()` and `get_rng()` respectively.

LP functions: If a user-defined Stan function ends in `_lp`, then it can modify the log-probability used by Stan to evaluate Metropolis proposals or as an objective function for optimization. When exposing such functions to R, a `lp__` argument will be added to the `formals`. This `lp__` argument defaults to zero, but a `double` precision scalar may be passed to this argument when the function is called from R. Such a user-defined Stan function can terminate with `return target();` or can execute `print(target());` to verify that the calculation is correct.

Value

The names of the new functions in `env` are returned invisibly.

See Also

`sourceCpp` and the section in the Stan User Manual on user-defined functions

Examples

```r
## Not run:
model_code <-

functions {
  real standard_normal_rng() {
    return normal_rng(0,1);
  }
},

expose_stan_functions(stanc(model_code = model_code))

standard_normal_rng()
PRNG <- get_rng(seed = 3)
o <- get_stream()
standard_normal_rng(PRNG, o)

## End(Not run)
```
Extract samples from a fitted Stan model

### Description

Extract samples from a fitted model represented by an instance of class `stanfit`.

### Usage

```r
## S4 method for signature 'stanfit'
extract(object, pars, permuted = TRUE, inc_warmup = FALSE, include = TRUE)
```

### Arguments

- `object`
  - An object of class `stanfit`.

- `pars`
  - An optional character vector providing the parameter names (or other quantity names) of interest. If not specified, all parameters and other quantities are used. The log-posterior with name `lp__` is also included by default.

- `permuted`
  - A logical scalar indicating whether the draws after the `warmup` period in each chain should be permuted and merged. If `FALSE`, the original order is kept. For each `stanfit` object, the permutation is fixed (i.e., extracting samples a second time will give the same sequence of iterations).

- `inc_warmup`
  - A logical scalar indicating whether to include the warmup draws. This argument is only relevant if `permuted` is `FALSE`.

- `include`
  - A logical scalar indicating whether the parameters named in `pars` should be included (`TRUE`) or excluded (`FALSE`).

### Value

When `permuted = TRUE`, this function returns a named list, every element of which is an array representing samples for a parameter with all chains merged together.

When `permuted = FALSE`, an array is returned; the first dimension is for the iterations, the second for the number of chains, the third for the parameters. Vectors and arrays are expanded to one parameter (a scalar) per cell, with names indicating the third dimension. See the examples (with comments) below. The `monitor` function can be applied to the returned array to obtain a summary (similar to the `print` method for `stanfit` objects).

### Methods

```r
extract signature(object = "stanfit")
```

Extract samples from a fitted model represented by an instance of class `stanfit`.

### See Also

S4 class `stanfit`, `as.array.stanfit`, and `monitor`
Examples

## Not run:
ex_model_code <- 'parameters {
    array[2, 3] real alpha;
    array[2] real beta;
}
model {
    for (i in 1:2) for (j in 1:3)
        alpha[i, j] ~ normal(0, 1);
    for (i in 1:2)
        beta ~ normal(0, 2);
}

## fit the model
fit <- stan(model_code = ex_model_code, chains = 4)

## extract alpha and beta with 'permutated = TRUE'
fit_ss <- extract(fit, permuted = TRUE) # fit_ss is a list
## list fit_ss should have elements with name 'alpha', 'beta', 'lp__'
alpha <- fit_ss$alpha
beta <- fit_ss$beta
## or extract alpha by just specifying pars = 'alpha'
alpha2 <- extract(fit, pars = 'alpha', permuted = TRUE)$alpha
print(identical(alpha, alpha2))

## or extract alpha by excluding beta and lp__
alpha3 <- extract(fit, pars = c('beta', 'lp__'),
    permuted = TRUE, include = FALSE)$alpha
print(identical(alpha, alpha3))

## get the samples for alpha[1,1] and beta[2]
alpha_11 <- alpha[, 1, 1]
beta_2 <- beta[, 2]

## extract samples with 'permutated = FALSE'
fit_ss2 <- extract(fit, permuted = FALSE) # fit_ss2 is an array

## the dimensions of fit_ss2 should be
## "# of iterations * # of chains * # of parameters"
dim(fit_ss2)

## since the third dimension of 'fit_ss2' indicates
## parameters, the names should be
## alpha[1,1], alpha[2,1], alpha[1,2], alpha[2,2],
## alpha[1,2], alpha[2,2], beta[1], beta[2], and lp__
## 'lp__' (the log-posterior) is always included
## in the samples.
dimnames(fit_ss2)

## End(Not run)

    for (i in 1:3)
        z[i] ~ normal(0, 1);
    alpha ~ exponential(2);
}
'

# exfit <- stan(model_code = excode, save_dso = FALSE, iter = 200,
# sample_file = "rstan_doc_ex.csv")
#
exfit <- read_stan_csv(dir(system.file(misc, package = rstan),
    pattern='rstan_doc_ex_[[:digit:]].csv',
    full.names = TRUE))

ee1 <- extract(exfit, permuted = TRUE)
print(names(ee1))
for (name in names(ee1)) {
    cat(name, "\n")
    print(dim(ee1[[name]]))
}

ee2 <- extract(exfit, permuted = FALSE)
print(dim(ee2))
print(dimnames(ee2))
Description

Create a list of vectors that represents a sparse matrix.

Usage

extract_sparse_parts(A)

Arguments

A A matrix or Matrix.

Details

The Stan Math Library has a function called csr_matrix_times_vector, which inputs a matrix in compressed row storage form and a dense vector and returns their product without fillin. To use the csr_matrix_times_vector function with a large sparse matrix, it is optimal in terms of memory to simply pass the three vectors that characterize the compressed row storage form of the matrix to the data block of the Stan program. The extract_sparse_parts function provides a convenient means of obtaining these vectors.

Value

A named list with components

1. w A numeric vector containing the non-zero elements of A.
2. v An integer vector containing the column indices of the non-zero elements of A.
3. u An integer vector indicating where in w a given row’s non-zero values start.

Examples

A <- rbind(
  c(19L, 27L, 0L, 0L),
  c(0L, 0L, 0L, 0L),
  c(0L, 0L, 0L, 52L),
  c(81L, 0L, 95L, 33L)
 )
str(extract_sparse_parts(A))

---

gqs

Draw samples of generated quantities from a Stan model

Description

Draw samples from the generated quantities block of a stanmodel.
Usage

```r
## S4 method for signature 'stanmodel'
gqs(object, data = list(), draws,
    seed = sample.int(.Machine$integer.max, size = 1L))
```

Arguments

- **object**: An object of class `stanmodel`.
- **data**: A named list or environment providing the data for the model or a character vector for all the names of objects used as data. See the **Passing data to Stan** section in `stan`.
- **draws**: A matrix of posterior draws, typically created by calling `as.matrix` on a `stanfit`.
- **seed**: The seed for random number generation. The default is generated from 1 to the maximum integer supported by R on the machine. When a seed is specified by a number, `as.integer` will be applied to it. If `as.integer` produces NA, the seed is generated randomly. The seed can also be specified as a character string of digits, such as "12345", which is converted to integer.

Value

An object of S4 class `stanmodel` representing the fitted results.

Methods

- `object signature(object = "stanmodel")` Evaluate the generated quantities block of a Stan program by supplying data and the draws output from a previous Stan program.

See Also

- `stanmodel`, `stanfit`, `stan`

Examples

```r
## Not run:
m <- stan_model(model_code = 'parameters {real y;} model {y ~ normal(0,1);}')
f <- sampling(m, iter = 300)
m2 <-

  parameters {real y;}
  generated quantities {real y_rep = normal_rng(y, 1);}

m2 <- stan_model(model_code = mc)
f2 <- gqs(m2, draws = as.matrix(f))
f2

## End(Not run)
```
Description

Using model's log_prob and grad_log_prob take values from the unconstrained space of model parameters and (by default) return values in the same space. Sometimes we need to convert the values of parameters from their support defined in the parameters block (which might be constrained, and for simplicity, we call it the constrained space) to the unconstrained space and vice versa. The constrain_pars and unconstrain_pars functions are used for this purpose.

Usage

```r
## S4 method for signature 'stanfit'
log_prob(object, upars, adjust_transform = TRUE, gradient = FALSE)

## S4 method for signature 'stanfit'
grad_log_prob(object, upars, adjust_transform = TRUE)

## S4 method for signature 'stanfit'
get_num_upars(object)

## S4 method for signature 'stanfit'
constrain_pars(object, upars)

## S4 method for signature 'stanfit'
unconstrain_pars(object, pars)
```

Arguments

- **object**: An object of class `stanfit`.
- **pars**: An list specifying the values for all parameters on the constrained space.
- **upars**: A numeric vector for specifying the values for all parameters on the unconstrained space.
- **adjust_transform**: Logical to indicate whether to adjust the log density since Stan transforms parameters to unconstrained space if it is in constrained space. Set to FALSE to make the function return the same values as Stan's `lp__` output.
- **gradient**: Logical to indicate whether gradients are also computed as well as the log density.

Details

Stan requires that parameters be defined along with their support. For example, for a variance parameter, we must define it on the positive real line. But inside Stan's samplers all parameters...
defined on the constrained space are transformed to an unconstrained space amenable to Hamiltonian Monte Carlo. Because of this, Stan adjusts the log density function by adding the log absolute value of the Jacobian determinant. Once a new iteration is drawn, Stan transforms the parameters back to the original constrained space without requiring interference from the user. However, when using the log density function for a model exposed to R, we need to be careful. For example, if we are interested in finding the mode of parameters on the constrained space, we then do not need the adjustment. For this reason, the log_prob and grad_log_prob functions accept an adjust_transform argument.

Value

log_prob returns a value (up to an additive constant) the log posterior. If gradient is TRUE, the gradients are also returned as an attribute with name gradient.

grad_log_prob returns a vector of the gradients. Additionally, the vector has an attribute named log_prob being the value the same as log_prob is called for the input parameters.

get_num_upars returns the number of parameters on the unconstrained space.

constrain_pars returns a list and unconstrain_pars returns a vector.

Methods

log_prob signature(object = "stanfit") Compute \( \log p(\cdot) \), the log posterior (up to an additive constant) for the model represented by a stanfit object. Note that, by default, log_prob returns the log posterior in the unconstrained space Stan works in internally. set adjust_transform = FALSE to make the values match Stan’s output.

grad_log_prob signature(object = "stanfit") Compute the gradients for log_prob as well as the log posterior. The latter is returned as an attribute.

get_num_upars signature(object = "stanfit") Get the number of unconstrained parameters.

constrain_pars signature(object = "stanfit") Convert values of the parameter from unconstrained space (given as a vector) to their constrained space (returned as a named list).

unconstrain_pars signature(object = "stanfit") Contrary to constrained, convert values of the parameters from constrained to unconstrained space.

Examples

```r
## Not run:
# see the examples in the help for stanfit as well
# do a simple optimization problem
opcode <- "
parameters {
```
```r
real y;
}
model {
  target += log(square(y - 5) + 1);
}

opfit <- stan(model_code = opcode, chains = 0)
tfun <- function(y) log_prob(opfit, y)
tgrfun <- function(y) grad_log_prob(opfit, y)
or <- optim(1, tfun, tgrfun, method = 'BFGS')
print(or)

# return the gradient as an attribute
tfun2 <- function(y) {
  g <- grad_log_prob(opfit, y)
  lp <- attr(g, "log_prob")
  attr(lp, "gradient") <- g
  lp
}

or2 <- nlm(tfun2, 10)
or2
## End(Not run)
```

### loo.stanfit

**Approximate leave-one-out cross-validation**

**Description**

A `loo` method that is customized for `stanfit` objects. The `loo` method for `stanfit` objects — a wrapper around the array method for `loo` in the `loo` package — computes PSIS-LOO CV, approximate leave-one-out cross-validation using Pareto smoothed importance sampling (Vehtari, Gelman, and Gabry, 2017a, 2017b).

**Usage**

```r
## S3 method for class 'stanfit'
loo(x, pars = "log_lik", save_psis = FALSE, cores =getOption("mc.cores", 1), moment_match = FALSE, k_threshold = 0.7, ...)
```

**Arguments**

- **x** An object of S4 class `stanfit`.  

pars  Name of transformed parameter or generated quantity in the Stan program corresponding to the pointwise log-likelihood. If not specified the default behavior is to look for "log_lik".

save_psis  Should the intermediate results from psis be saved in the returned object? The default is FALSE. This can be useful to avoid repeated computation when using other functions in the loo and bayesplot packages.

cores  Number of cores to use for parallelization. The default is 1 unless cores is specified or the mc.cores option has been set.

moment_match  Logical; Whether to use the moment matching algorithm for observations with high Pareto k values to improve accuracy. Note: because the moment matching algorithm relies on the unconstrain_pars method in RStan it is only available if run in the same R session as fitting the model.

k_threshold  Threshold value for Pareto k values above which the moment matching algorithm is used. If moment_match is FALSE, this is ignored.

...  Ignored.

Details

Stan does not automatically compute and store the log-likelihood. It is up to the user to incorporate it into the Stan program if it is to be extracted after fitting the model. In a Stan program, the pointwise log likelihood can be coded as a vector in the transformed parameters block (and then summed up in the model block) or it can be coded entirely in the generated quantities block. We recommend using the generated quantities block so that the computations are carried out only once per iteration rather than once per HMC leapfrog step.

For example, the following is the generated quantities block for computing and saving the log-likelihood for a linear regression model with N data points, outcome y, predictor matrix X (including column of 1s for intercept), coefficients beta, and standard deviation sigma:

```stan
vector[N] log_lik;
for (n in 1:N) log_lik[n] = normal_lpdf(y[n] | X[n, ] * beta, sigma);
```

This function automatically uses Pareto k diagnostics for assessing the accuracy of importance sampling for each observation. When the diagnostics indicate that importance sampling for certain observations is inaccurate, a moment matching algorithm can be used, which can improve the accuracy (Paananen et al., 2020).

Value

A list with class c("psis_loo", "loo"). as detailed in the loo documentation.

References

See Also

- The loo package documentation, including the vignettes for many examples (https://mc-stan.org/loo/).
- loo_moment_match for the moment matching algorithm.
- loo_model_weights for model averaging/weighting via stacking or pseudo-BMA weighting.

Examples

```r
## Not run:
# Generate a dataset from N(0,1)
N <- 100
y <- rnorm(N, 0, 1)

# Suppose we have three models for y:
# 1) y ~ N(-1, sigma)
# 2) y ~ N(0.5, sigma)
# 3) y ~ N(0.6,sigma)
#
# stan_code <- 
data {
  int N;
  vector[N] y;
  real mu_fixed;
}
parameters {
  real<lower=0> sigma;
}
model {
  sigma ~ exponential(1);
  y ~ normal(mu_fixed, sigma);
}
generated quantities {
  vector[N] log_lik;
  for (n in 1:N) log_lik[n] = normal_lpdf(y[n]| mu_fixed, sigma);
}

mod <- stan_model(model_code = stan_code)
fit1 <- sampling(mod, data=list(N=N, y=y, mu_fixed=-1))
fit2 <- sampling(mod, data=list(N=N, y=y, mu_fixed=0.5))
fit3 <- sampling(mod, data=list(N=N, y=y, mu_fixed=0.6))

# use the loo method for stanfit objects
loo1 <- loo(fit1, pars = "log_lik")
print(loo1)
```
# which is equivalent to
LL <- as.array(fit1, pars = "log_lik")
r_eff <- loo::relative_eff(exp(LL))
loo1b <- loo::loo.array(LL, r_eff = r_eff)
print(loo1b)

# compute loo for the other models
loo2 <- loo(fit2)
loo3 <- loo(fit3)

# stacking weights
wts <- loo::loo_model_weights(list(loo1, loo2, loo3), method = "stacking")
print(wts)

# use the moment matching for loo with a stanfit object
loo_mm <- loo(fit1, pars = "log_lik", moment_match = TRUE)
print(loo_mm)

### End(Not run)

## End(Not run)

---

### lookup

*Look up the Stan function that corresponds to a R function or name.*

#### Description

This function helps to map between R functions and Stan functions.

#### Usage

```r
lookup(FUN, ReturnType = character())
```

#### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FUN</td>
<td>A character string naming a R function or a R function for which the (near) equivalent Stan function is sought. If no matching R function is found, FUN is reinterpreted as a regexp and matches are sought.</td>
</tr>
<tr>
<td>ReturnType</td>
<td>A character string of positive length naming a valid return type for a Stan function: <code>int</code>, <code>int[]</code>, <code>matrix</code>, <code>real</code>, <code>real[]</code>, <code>real[,]</code>, <code>row_vector</code>, <code>T[]</code>, <code>vector</code>, or <code>void</code>. If &quot;ANY&quot; is passed, then the entire <code>data.frame</code> is returned and can be inspected with the <code>View</code> function, for example.</td>
</tr>
</tbody>
</table>

#### Value

Ordinarily, a `data.frame` with rows equal to the number of partial matches and four columns:

1. **StanFunction** Character string for the Stan function’s name.
2. **Arguments** Character string indicating the arguments to that Stan function.
3. **ReturnType** Character string indicating the return type of that Stan function.
4. Page Integer indicating the page of the Stan reference manual where that Stan function is defined.

If there are no matching Stan functions, a character string indicating so is returned.

References

Examples

```r
lookup(dnorm)       # Stan equivalents for the normal PDF (in log form)
lookup("foo")      # fails
lookup("Student")  # succeeds even though there is no such R function
lookup("^poisson") # every Stan function that starts with poisson
```

---

**loo_moment_match.stanfit**

*Moment matching for efficient approximate leave-one-out cross-validation (LOO)*

Description

A `loo_moment_match` method that is customized for stanfit objects. The `loo_moment_match` method for stanfit objects —a wrapper around the `loo_moment_match` (`loo` package)— updates a loo object using moment matching (Paananen et al., 2020).

Usage

```r
## S3 method for class 'stanfit'
loo_moment_match(x, 
    loo = loo, 
    ...)
```

Arguments

- **x** An object of S4 class stanfit.
- **loo** A loo object that is modified.
- **...** Further arguments.

Value

The `loo_moment_match()` methods return an updated loo object.
References

loo(), loo_moment_match()

makeconf_path

Obtain the full path of file Makeconf

Description

Obtain the full path of file Makeconf, in which, for example the flags for compiling C/C++ code are configured.

Usage

makeconf_path()

Details

The configuration for compiling shared objects using R CMD SHLIB are set in file Makeconf. To change how the C++ code is compiled, modify this file. For RStan, package inline compiles the C++ code using R CMD SHLIB. To speed up compiled Stan models, increase the optimization level to -O3 defined in property CXXFLAGS in the file Makeconf. This file may also be modified to specify alternative C++ compilers, such as clang++ or later versions of g++.

Value

An character string for the full path of file Makeconf.

See Also

stan

Examples

makeconf_path()
**monitor**

*Compute summaries of MCMC draws and monitor convergence*

**Description**

Similar to the print method for stanfit objects, but monitor takes an array of simulations as its argument rather than a stanfit object. For a 3-D array (iterations * chains * parameters) of MCMC draws, monitor computes means, standard deviations, quantiles, Monte Carlo standard errors, split Rhats, and effective sample sizes. By default, half of the iterations are considered warmup and are excluded.

**Usage**

```r
monitor(sims, warmup = floor(dim(sims)[1]/2),
        probs = c(0.025, 0.25, 0.5, 0.75, 0.975),
        digits_summary = 1, print = TRUE, ...)
```

**Arguments**

- **sims**: A 3-D array (iterations * chains * parameters) of MCMC simulations from any MCMC algorithm.
- **warmup**: The number of warmup iterations to be excluded when computing the summaries. The default is half of the total number of iterations. If `sims` doesn’t include the warmup iterations then `warmup` should be set to zero.
- **probs**: A numeric vector specifying quantiles of interest. The defaults is `c(0.025, 0.25, 0.5, 0.75, 0.975)`.
- **digits_summary**: The number of significant digits to use when printing the summary, defaulting to 1. Applies to the quantities other than the effective sample size, which is always rounded to the nearest integer.
- **print**: Logical, indicating whether to print the summary after the computations are performed.
- **...**: Additional arguments passed to the underlying print method.
- **x**: An object of class `simsummary` created by monitor
- **digits**: An integer scalar defaulting to 3 for the number of decimal places to print
- **se**: A logical scalar defaulting to `FALSE` indicating whether to print the estimated standard errors of the estimates
- **i**: A vector indicating which rows of the object created by monitor to select
- **j**: A vector indicating which columns of the object created by monitor to select
- **drop**: A logical scalar indicating whether the resulting object should return a vector where possible
Value

A 2-D array with rows corresponding to parameters and columns to the summary statistics that can be printed and subset.

S4 class stanfit and particularly its print method.

Examples

csvfiles <- dir(system.file('misc', package = 'rstan'),
pattern = 'rstan_doc_ex_[0-9].csv', full.names = TRUE)
fit <- read_stan_csv(csvfiles)
# The following is just for the purpose of giving an example
# since print can be used for a stanfit object.
monitor(extract(fit, permuted = FALSE, inc_warmup = TRUE))

nlist (Created named lists)

Description

Create a named list using specified names or, if names are omitted, using the names of the objects in the list. The code list(a = a, b = b) becomes nlist(a, b) and list(a = a, b = 2) becomes nlist(a, b = 2), etc. This is convenient when creating the list of data to pass to Stan.

Usage

nlist(...)

Arguments

... The objects to include in the list.

Value

A named list.
Examples

# All variables already defined
x <- 1
y <- 2
nlist(x, y)

# Define some variables in the call and take the rest from the environment
nlist(x, y, z = 3)

optimizing

Obtain a point estimate by maximizing the joint posterior

Description

Obtain a point estimate by maximizing the joint posterior from the model defined by class `stanmodel`.

Usage

```r
## S4 method for signature 'stanmodel'
optimizing(object, data = list(),
            seed = sample.int(.Machine$integer.max, 1), init = 'random',
            check_data = TRUE, sample_file = NULL,
            algorithm = c("LBFGS", "BFGS", "Newton"),
            verbose = FALSE, hessian = FALSE, as_vector = TRUE,
            draws = 0, constrained = TRUE, importance_resampling = FALSE, ...)
```

Arguments

- **object**: An object of class `stanmodel`.
- **data**: A named list or environment providing the data for the model or a character vector for all the names of objects used as data. See the **Passing data to Stan** section in `stan`.
- **seed**: The seed for random number generation. The default is generated from 1 to the maximum integer supported by R on the machine. Even if multiple chains are used, only one seed is needed, with other chains having seeds derived from that of the first chain to avoid dependent samples. When a seed is specified by a number, `as.integer` will be applied to it. If `as.integer` produces NA, the seed is generated randomly. The seed can also be specified as a character string of digits, such as "12345", which is converted to integer.
- **init**: Initial values specification. See the detailed documentation for the `init` argument in `stan` with one exception. If specifying inits using a list then only a single named list of values should be provided. For example, to initialize a parameter alpha to value1 and beta to value2 you can specify `list(alpha = value1, beta = value2)`.
check_data Logical, defaulting to TRUE. If TRUE the data will be preprocessed; otherwise not. See the Passing data to Stan section in stan.

sample_file A character string of file name for specifying where to write samples for all parameters and other saved quantities. If not provided, files are not created. When the folder specified is not writable, tempdir() is used.

algorithm One of "Newton", "BFGS", and "LBFGS" (the default) indicating which optimization algorithm to use.

verbose TRUE or FALSE (the default): flag indicating whether to print intermediate output from Stan on the console, which might be helpful for model debugging.

hessian TRUE or FALSE (the default): flag indicating whether to calculate the Hessian (via numeric differentiation of the gradient function in the unconstrained parameter space).

as_vector TRUE (the default) or FALSE: flag indicating whether a vector is used to store the point estimate found. A list can be used instead by specifying it to be FALSE.

draws A non-negative integer (that defaults to zero) indicating how many times to draw from a multivariate normal distribution whose parameters are the mean vector and the inverse negative Hessian in the unconstrained space. If draws > 0 and importance_resampling=TRUE then log_p and log_g will be computed and returned (see description in the Value section).

constrained A logical scalar indicating, if draws > 0, whether the draws should be transformed to the constrained space defined in the parameters block of the Stan program. Defaults to TRUE.

importance_resampling A logical scalar (defaulting to FALSE) indicating whether to do importance resampling to compute diagnostics on the draws from the normal approximation to the posterior distribution. If TRUE and draws > 0 then log_p and log_g will be computed and returned (see description in the Value section).

... Other optional parameters:

• iter (integer), the maximum number of iterations, defaulting to 2000.
• save_iterations (logical), a flag indicating whether to save the iterations, defaulting to FALSE.
• refresh (integer), the number of interations between screen updates, defaulting to 100.
• init_alpha (double), for BFGS and LBFGS, the line search step size for first iteration, defaulting to 0.001.
• tol_obj (double), for BFGS and LBFGS, the convergence tolerance on changes in objective function value, defaulting to 1e-12.
• tol_rel_obj (double), for BFGS and LBFGS, the convergence tolerance on relative changes in objective function value, defaulting to 1e-4.
• tol_grad (double), for BFGS and LBFGS, the convergence tolerance on the norm of the gradient, defaulting to 1e-8.
• tol_rel_grad (double), for BFGS and LBFGS, the convergence tolerance on the relative norm of the gradient, defaulting to 1e7.
• tol_param (double), for BFGS and LBFGS, the convergence tolerance on changes in parameter value, defaulting to 1e-8.
• history_size (integer), for LBFGS, the number of update vectors to use in Hessian approximations, defaulting to 5.

Refer to the manuals for both CmdStan and Stan for more details.

Value

A list with components:

- `par` The point estimate found. Its form (vector or list) is determined by the `as_vector` argument.
- `value` The value of the log-posterior (up to an additive constant, the “lp__” in Stan) corresponding to `par`.
- `return_code` The value of the return code from the optimizer; anything that is not zero is problematic.
- `hessian` The Hessian matrix if `hessian` is TRUE
- `theta_tilde` If `draws > 0`, the matrix of parameter draws in the constrained or unconstrained space, depending on the value of the `constrained` argument.
- `log_p` If `draws > 0` and `importance_resampling=TRUE`, a vector of length `draws` that contains the value of the log-posterior evaluated at each row of `theta_tilde`.
- `log_g` If `draws > 0`, a vector of length `draws` that contains the value of the logarithm of the multivariate normal density evaluated at each row of `theta_tilde`.

If the optimization is not completed for reasons such as feeding wrong data, it returns NULL.

Methods

`optimizing` signature(object = "stanmodel") Call Stan's optimization methods to obtain a point estimate for the model defined by S4 class `stanmodel` given the data, initial values, etc.

See Also

`stanmodel`

Examples

```r
## Not run:
m <- stan_model(model_code = 'parameters {real y;} model {y ~ normal(0,1);}')
f <- optimizing(m, hessian = TRUE)
## End(Not run)
```
pairs.stanfit

Create a matrix of output plots from a stanfit object

Description

A pairs method that is customized for MCMC output

Usage

```r
## S3 method for class 'stanfit'
pairs(x, labels = NULL, panel = NULL, ...,
lower.panel = NULL,
upper.panel = NULL, diag.panel = NULL, text.panel = NULL,
label.pos = 0.5 + 1/3, cex.labels = NULL, font.labels = 1,
rowlattop = TRUE, gap = 1, log = "", pars = NULL, include = TRUE,
condition = "accept_stat__")
```

Arguments

- `x` An object of S4 class stanfit
- `labels, panel, ..., lower.panel, upper.panel, diag.panel`
  Same as in `pairs` syntactically but see the Details section for different default arguments
- `text.panel, label.pos, cex.labels, font.labels, rowlattop, gap`
  Same as in `pairs.default`
- `log`
  Same as in `pairs.default`, which makes it possible to utilize logarithmic axes and additionally accepts `log = TRUE`. See the Details section.
- `pars`
  If not NULL, a character vector indicating which quantities to include in the plots, which is passed to `extract`. Thus, by default, all unknown quantities are included, which may be far too many to visualize on a small computer screen. If `include = FALSE`, then the named parameters are excluded from the plot.
- `condition`
  If NULL, it will plot roughly half of the chains in the lower panel and the rest in the upper panel. An integer vector can be passed to select some subset of the chains, of which roughly half will be plotted in the lower panel and the rest in the upper panel. A list of two integer vectors can be passed, each specifying a subset of the chains to be plotted in the lower and upper panels respectively. A single number between zero and one exclusive can be passed, which is interpreted as the proportion of realizations (among all chains) to plot in the lower panel starting with the first realization in each chain, with the complement (from the end of each chain) plotted in the upper panel. A (possibly abbreviated) character vector of length one can be passed among "accept_stat__", "stepsize__", "treedept__", "n_leapfrog__", "divergent__", "energy__", or "lp__", which are the variables produced by `get_sampler_params` and `get_logposterior`. In that case the lower panel will plot realizations that are below the median of the indicated variable (or are zero in the case
of "divergent__") and the upper panel will plot realizations that are greater than or equal to the median of the indicated variable (or are one in the case of "divergent__"). Finally, any logical vector whose length is equal to the product of the number of iterations and the number of chains can be passed, in which case realizations corresponding to FALSE and TRUE will be plotted in the lower and upper panel respectively. The default is "accept_stat__".

include Logical scalar indicating whether to include (the default) or exclude the parameters named in the pars argument from the plot.

Details

This method differs from the default pairs method in the following ways. If unspecified, the smoothScatter function is used for the off-diagonal plots, rather than points, since the former is more appropriate for visualizing thousands of draws from a posterior distribution. Also, if unspecified, histograms of the marginal distribution of each quantity are placed on the diagonal of the plot, after pooling all of the chains specified by the chain\_id argument.

The draws from the warmup phase are always discarded before plotting.

By default, the lower (upper) triangle of the plot contains draws with below (above) median acceptance probability. Also, if condition is not "divergent__", red points will be superimposed onto the smoothed density plots indicating which (if any) iterations encountered a divergent transition. Otherwise, yellow points indicate a transition that hit the maximum treedepth rather than terminated its evolution normally.

You may very well want to specify the log argument for non-negative parameters. However, the pairs function will drop (with a message) parameters that are either constant or duplicative with previous parameters. For example, if a correlation matrix is included among pars, then neither its diagonal elements (which are always 1) nor its upper triangular elements (which are the same as the corresponding lower triangular elements) will be included. Thus, if log is an integer vector, it needs to pertain to the parameters after constant and duplicative ones are dropped. It is perhaps easiest to specify log = TRUE, which will utilize logarithmic axes for all non-negative parameters, except lp__ and any integer valued quantities.

See Also

S4 class stanfit and its method extract as well as the pairs generic function. Also, see get_sampler_params and get_logposterior.

Examples

element(read_stan_csv)
pairs(fit, pars = c("mu", "sigma", "alpha", "lp__"), log = TRUE, las = 1)
# sigma and alpha will have logarithmic axes
Plots for stanfit objects

Description

The default plot shows posterior uncertainty intervals and point estimates for parameters and generated quantities. The plot method can also be used to call the other rstan plotting functions via the plotfun argument (see Examples).

Usage

```r
## S4 method for signature 'stanfit,missing'
plot(x, ..., plotfun)
```

Arguments

- `x` An instance of class `stanfit`.
- `plotfun` A character string naming the plotting function to apply to the stanfit object. If `plotfun` is missing, the default is to call `stan_plot`, which generates a plot of credible intervals and point estimates. See `rstan-plotting-functions` for the names and descriptions of the other plotting functions. `plotfun` can be either the full name of the plotting function (e.g. "stan_hist") or can be abbreviated to the part of the name following the underscore (e.g. "hist").
- `...` Optional arguments to `plotfun`.

Value

A `ggplot` object that can be further customized using the `ggplot2` package.

Note

Because the rstan plotting functions use `ggplot2` (and thus the resulting plots behave like `ggplot` objects), when calling a plotting function within a loop or when assigning a plot to a name (e.g., `graph <- plot(fit, plotfun = "rhat"),` if you also want the side effect of the plot being displayed you must explicitly print it (e.g., `(graph <- plot(fit, plotfun = "rhat")), print(graph <- plot(fit, plotfun = "rhat"))`).

Examples

```r
## Not run:
library(rstan)
fit <- stan_demo("eight_schools")
plot(fit)
plot(fit, show_density = TRUE, ci_level = 0.5, fill_color = "purple")
```
```r
plot(fit, plotfun = "hist", pars = "theta", include = FALSE)
plot(fit, plotfun = "trace", pars = c("mu", "tau"), inc_warmup = TRUE)
plot(fit, plotfun = "rhat") + ggtitle("Example of adding title to plot")
```

### ggplot2 for RStan

#### Description

Visual posterior analysis using ggplot2.

#### Usage

```r
stan_plot(object, pars, include = TRUE, unconstrain = FALSE, ...)
stan_trace(object, pars, include = TRUE, unconstrain = FALSE,
           inc_warmup = FALSE, nrow = NULL, ncol = NULL, ...,
           window = NULL)
stan_scat(object, pars, unconstrain = FALSE,
           inc_warmup = FALSE, nrow = NULL, ncol = NULL, ...)
stan_hist(object, pars, include = TRUE, unconstrain = FALSE,
           inc_warmup = FALSE, nrow = NULL, ncol = NULL, ...)
stan_dens(object, pars, include = TRUE, unconstrain = FALSE,
           inc_warmup = FALSE, nrow = NULL, ncol = NULL, ..., separate_chains = FALSE)
stan_ac(object, pars, include = TRUE, unconstrain = FALSE,
           inc_warmup = FALSE, nrow = NULL, ncol = NULL, ..., separate_chains = FALSE, lags = 25, partial = FALSE)
quietgg(gg)
```

#### Arguments

- **object**: A stanfit or stanreg object.
- **pars**: Optional character vector of parameter names. If object is a stanfit object, the default is to show all user-defined parameters or the first 10 (if there are more than 10). If object is a stanreg object, the default is to show all (or the first 10) regression coefficients (including the intercept). For `stan_scat` only, `pars` should not be missing and should contain exactly two parameter names.
- **include**: Should the parameters given by the `pars` argument be included (the default) or excluded from the plot?
- **unconstrain**: Should parameters be plotted on the unconstrained space? Defaults to `FALSE`. Only available if `object` is a stanfit object.
- **inc_warmup**: Should warmup iterations be included? Defaults to `FALSE`.
- **nrow,ncol**: Passed to `facet_wrap`.
... Optional additional named arguments passed to geoms (e.g. for stan_trace the geom is geom_path and we could specify linetype, size, alpha, etc.). For stan_plot there are also additional arguments that can be specified in ... (see Details).

window For stan_trace window is used to control which iterations are shown in the plot. See traceplot.

separate_chains For stan_dens, should the density for each chain be plotted? The default is FALSE, which means that for each parameter the draws from all chains are combined. For stan_ac, if separate_chains=FALSE (the default), the autocorrelation is averaged over the chains. If TRUE each chain is plotted separately.

lags For stan_ac, the maximum number of lags to show.

partial For stan_ac, should partial autocorrelations be plotted instead? Defaults to FALSE.

gg A ggplot object or an expression that creates one.

Details

For stan_plot, there are additional arguments that can be specified in ... The optional arguments and their default values are:

point_est = "median" The point estimate to show. Either "median" or "mean".

show_density = FALSE Should kernel density estimates be plotted above the intervals?

cl_level = 0.8 The posterior uncertainty interval to highlight. Central 100*cl_level% intervals are computed from the quantiles of the posterior draws.

outer_level = 0.95 An outer interval to also draw as a line (if show_outer_line is TRUE) but not highlight.

show_outer_line = TRUE Should the outer_level interval be shown or hidden? Defaults to = TRUE (to plot it).

fill_color, outline_color, est_color Colors to override the defaults for the highlighted interval, the outer interval (and density outline), and the point estimate.

Value

A ggplot object that can be further customized using the ggplot2 package.

Note

Because the rstan plotting functions use ggplot2 (and thus the resulting plots behave like ggplot objects), when calling a plotting function within a loop or when assigning a plot to a name (e.g., graph <- plot(fit, plotfun = "rhat")), if you also want the side effect of the plot being displayed you must explicitly print it (e.g., (graph <- plot(fit, plotfun = "rhat")), print(graph <- plot(fit, plotfun = "rhat"))).

---

**Print a summary for a fitted model represented by a stanfit object**

### Description

Print basic information regarding the fitted model and a summary for the parameters of interest estimated by the samples included in a stanfit object.

### Usage

```r
## S3 method for class 'stanfit'
print(x, pars = x@sim$pars_oi,
     probs = c(0.025, 0.25, 0.5, 0.75, 0.975),
     digits_summary = 2, include = TRUE, ...)
```

### Arguments

- `x` An object of S4 class stanfit.
- `pars` A character vector of parameter names. The default is all parameters for which samples are saved. If `include = FALSE`, then the specified parameters are excluded from the printed summary.
- `probs` A numeric vector of quantiles of interest. The default is `c(0.025, 0.25, 0.5, 0.75, 0.975)`. Applies to the quantities other than the effective sample size, which is always rounded to the nearest integer.
- `digits_summary` The number of significant digits to use when printing the summary, defaulting to 2.
- `include` Logical scalar (defaulting to `TRUE`) indicating whether to include or exclude the parameters named by the `pars` argument.
- `...` Additional arguments passed to the `summary` method for stanfit objects.

### Details

The information regarding the fitted model includes the number of iterations, the number of chains, the total number of saved iterations, the estimation algorithm used, and the timestamp indicating when sampling finished.

The parameter summaries computed include means, standard deviations (sd), quantiles, Monte Carlo standard errors (se_mean), split Rhats, and effective sample sizes (n_eff). The summaries are computed after dropping the warmup iterations and merging together the draws from all chains.

In addition to the model parameters, summaries for the log-posterior (lp__) are also reported.
read_rdump

Read data in an R dump file to a list

Description

Create an R list from an R dump file

Usage

read_rdump(f, keep.source = FALSE, ...)

Arguments

f
A character string providing the dump file name.

keep.source
logical: should the source formatting be retained when echoing expressions, if possible?

...
passed to source

Details

The R dump file can be read directly by R function source, which by default would read the data into the user's workspace (the global environment). This function instead read the data to a list, making it convenient to prepare data for the stan model-fitting function.

Value

A list containing all the data defined in the dump file with keys corresponding to variable names.

See Also

stan_rdump; dump

Examples

x <- 1; y <- 1:10; z <- array(1:10, dim = c(2,5))
stan_rdump(ls(pattern = "^[xyz]"), file.path(tempdir(), "xyz.Rdump"))
l <- read_rdump(file.path(tempdir(), "xyz.Rdump"))
print(l)
unlink(file.path(tempdir(), "xyz.Rdump"))

See Also

S4 class stanfit and particularly its method summary, which is used to obtain the values that are printed.
read_stan_csv

Read CSV files of samples generated by (R)Stan into a stanfit object

Description

Create a stanfit object from the saved CSV files that are created by Stan or RStan and that include the samples drawn from the distribution of interest to facilitate analysis of samples using RStan.

Usage

read_stan_csv(csvfiles, col_major = TRUE)

Arguments

csvfiles A character vector providing CSV file names

col_major The order for array parameters; default to TRUE

Details

Stan and RStan could save the samples to CSV files. This function reads the samples and using the comments (beginning with "#") to create a stanfit object. The model name is derived from the first CSV file.

col_major specifies how array parameters are ordered in each row of the CSV files. For example, parameter "a[2,2]" would be ordered as "a[1,1], a[2,1], a[1,2], a[2,2]" if col_major is TRUE.

Value

A stanfit object (with invalid stanmodel slot). This stanfit object cannot be used to re-run the sampler.

See Also

stanfit

Examples

csvfiles <- dir(system.file('misc', package = 'rstan'),
               pattern = 'rstan_doc_ex_[0-9].csv', full.names = TRUE)
fit <- read_stan_csv(csvfiles)
Description

These functions are improved versions of the traditional Rhat (for convergence) and Effective Sample Size (for efficiency).

Usage

\[
\text{Rhat}(sims)
\]
\[
\text{ess\_bulk}(sims)
\]
\[
\text{ess\_tail}(sims)
\]

Arguments

\text{sims} \quad \text{A two-dimensional array whose rows are equal to the number of iterations of the Markov Chain(s) and whose columns are equal to the number of Markov Chains (preferably more than one). The cells are the realized draws for a particular parameter or function of parameters.}

Value

The Rhat function produces R-hat convergence diagnostic, which compares the between- and within-chain estimates for model parameters and other univariate quantities of interest. If chains have not mixed well (i.e., the between- and within-chain estimates don't agree), R-hat is larger than 1. We recommend running at least four chains by default and only using the sample if R-hat is less than 1.05. Stan reports R-hat which is the maximum of rank normalized split-R-hat and rank normalized folded-split-R-hat, which works for thick-tailed distributions and is sensitive also to differences in scale.

The ess\_bulk function produces an estimated Bulk Effective Sample Size (bulk-ESS) using rank normalized draws. Bulk-ESS is a useful measure for sampling efficiency in the bulk of the distribution (related e.g., to efficiency of mean and median estimates), and is well defined even if the chains do not have finite mean or variance.

The ess\_tail function produces an estimated Tail Effective Sample Size (tail-ESS) by computing the minimum of effective sample sizes for 5% and 95% quantiles. Tail-ESS is a useful measure for sampling efficiency in the tails of the distribution (related e.g., to efficiency of variance and tail quantile estimates).

Both bulk-ESS and tail-ESS should be at least 100 (approximately) per Markov Chain in order to be reliable and indicate that estimates of respective posterior quantiles are reliable.

rstan_options

Set and read options used in RStan

Description

Set and read options used in RStan. Some settings as options can be controlled by the user.

Usage

rstan_options(...)

Arguments

...  Arguments of the form opt = val set option opt to value val. Arguments of the form opt set the function to return option opt’s value. Each argument must be a character string.

Details

The available options are:

1. plot_rhat_breaks: The cut off points for Rhat for which we would indicate using a different color. This is a numeric vector, defaulting to c(1.1, 1.2, 1.5, 2). The value for this option will be sorted in ascending order, so for example plot_rhat_breaks = c(1.2, 1.5) is equivalent to plot_rhat_breaks = c(1.5, 1.2).
2. plot_rhat_cols: A vector of the same length as plot_rhat_breaks that indicates the colors for the breaks.
3. plot_rhat_nan_col: The color for Rhat when it is Inf or NaN.
4. plot_rhat_large_col: The color for Rhat when it is larger than the largest value of plot_rhat_breaks.
5. rstan_alert_col: The color used in method plot of S4 class stanfit to show that the vector/array parameters are truncated.
6. rstan_chain_cols: The colors used in methods plot and traceplot of S4 class stanfit for coloring different chains.
7. rstan_warmup_bg_col: The background color for the warmup area in the traceplots.
8. boost_lib: The path for the Boost C++ library used to compile Stan models. This option is valid for the whole R session if not changed again.
9. eigen_lib: The path for the Eigen C++ library used to compile Stan models. This option is valid for the whole R session if not changed again.
10. auto_write: A logical scalar (defaulting to FALSE) that controls whether a compiled instance of a stanmodel-class is written to the hard disk in the same directory as the .stan program.
11. threads_per_chain: A positive integer (defaulting to 1). If the model was compiled with threading support, the number of threads to use in parallelized sections _within_ an MCMC chain (e.g., when using the Stan functions ‘reduce_sum()’ or ‘map_rect()’). The actual number of CPU cores used is ‘chains * threads_per_chain’ where ‘chains’ is the number of parallel chains. For an example of using threading, see the Stan case study [Reduce Sum: A Minimal Example](https://mc-stan.org/users/documentation/case-studies/reduce_sum_tutorial.html).
Value

The values as a list for existing options and NA for non-existent options. When only one option is specified, its old value is returned.

---

sampling

Draw samples from a Stan model

Description

Draw samples from the model defined by class stanmodel.

Usage

```r
## S4 method for signature 'stanmodel'
sampling(object, data = list(), pars = NA,
          chains = 4, iter = 2000, warmup = floor(iter/2), thin = 1,
          seed = sample.int(.Machine$integer.max, 1),
          init = 'random', check_data = TRUE,
          sample_file = NULL, diagnostic_file = NULL, verbose = FALSE,
          algorithm = c("NUTS", "HMC", "Fixed_param"),
          control = NULL, include = TRUE,
          cores = getOption("mc.cores", 1L),
          open_progress = interactive() && !isatty(stdout()) &&
                          !identical(Sys.getenv("RSTUDIO"), "1"),
          show_messages = TRUE, ...)
```

Arguments

- `object` An object of class `stanmodel`.
- `data` A named list or environment providing the data for the model or a character vector for all the names of objects used as data. See the Passing data to Stan section in `stan`.
- `pars` A vector of character strings specifying parameters of interest. The default is NA indicating all parameters in the model. If `include = TRUE`, only samples for parameters named in `pars` are stored in the fitted results. Conversely, if `include = FALSE`, samples for all parameters except those named in `pars` are stored in the fitted results.
- `chains` A positive integer specifying the number of Markov chains. The default is 4.
- `iter` A positive integer specifying the number of iterations for each chain (including warmup). The default is 2000.
- `warmup` A positive integer specifying the number of warmup (aka burnin) iterations per chain. If step-size adaptation is on (which it is by default), this also controls the number of iterations for which adaptation is run (and hence these warmup samples should not be used for inference). The number of warmup iterations should be smaller than `iter` and the default is `iter/2`. 
### sampling

**thin**
A positive integer specifying the period for saving samples. The default is 1, which is usually the recommended value.

**seed**
The seed for random number generation. The default is generated from 1 to the maximum integer supported by R on the machine. Even if multiple chains are used, only one seed is needed, with other chains having seeds derived from that of the first chain to avoid dependent samples. When a seed is specified by a number, `as.integer` will be applied to it. If `as.integer` produces `NA`, the seed is generated randomly. The seed can also be specified as a character string of digits, such as "12345", which is converted to integer.

**init**
Initial values specification. See the detailed documentation for the init argument in `stan`.

**check_data**
Logical, defaulting to `TRUE`. If `TRUE` the data will be preprocessed; otherwise not. See the **Passing data to Stan** section in `stan`.

**sample_file**
An optional character string providing the name of a file. If specified the draws for all parameters and other saved quantities will be written to the file. If not provided, files are not created. When the folder specified is not writable, `tempdir()` is used. When there are multiple chains, an underscore and chain number are appended to the file name prior to the `.csv` extension.

**diagnostic_file**
An optional character string providing the name of a file. If specified the diagnostics data for all parameters will be written to the file. If not provided, files are not created. When the folder specified is not writable, `tempdir()` is used. When there are multiple chains, an underscore and chain number are appended to the file name prior to the `.csv` extension.

**verbose**
`TRUE` or `FALSE`: flag indicating whether to print intermediate output from Stan on the console, which might be helpful for model debugging.

**algorithm**
One of sampling algorithms that are implemented in Stan. Current options are "NUTS" (No-U-Turn sampler, Hoffman and Gelman 2011, Betancourt 2017), "HMC" (static HMC), or "Fixed_param". The default and preferred algorithm is "NUTS".

**control**
A named list of parameters to control the sampler’s behavior. See the details in the documentation for the control argument in `stan`.

**include**
Logical scalar defaulting to `TRUE` indicating whether to include or exclude the parameters given by the `pars` argument. If `FALSE`, only entire multidimensional parameters can be excluded, rather than particular elements of them.

**cores**
Number of cores to use when executing the chains in parallel, which defaults to 1 but we recommend setting the `mc.cores` option to be as many processors as the hardware and RAM allow (up to the number of chains).

**open_progress**
Logical scalar that only takes effect if `cores > 1` but is recommended to be `TRUE` in interactive use so that the progress of the chains will be redirected to a file that is automatically opened for inspection. For very short runs, the user might prefer `FALSE`.

**show_messages**
Either a logical scalar (defaulting to `TRUE`) indicating whether to print the summary of Informational Messages to the screen after a chain is finished or a character string naming a path where the summary is stored. Setting to `FALSE` is not
recommended unless you are very sure that the model is correct up to numerical error.

Additional arguments can be chain_id, init_r, test_grad, append_samples, refresh, enable_random_init. See the documentation in stan.

Value

An object of S4 class stanfit representing the fitted results. Slot mode for this object indicates if the sampling is done or not.

Methods

sampling signature(object = "stanmodel") Call a sampler (NUTS, HMC, or Fixed_param depending on parameters) to draw samples from the model defined by S4 class stanmodel given the data, initial values, etc.

See Also

stanmodel, stanfit, stan

Examples

## Not run:
m <- stan_model(model_code = "parameters {real y;} model {y ~ normal(0,1);}")
f <- sampling(m, iter = 100)

## End(Not run)

sbc Simulation Based Calibration (sbc)

Description

Check whether a model is well-calibrated with respect to the prior distribution and hence possibly amenable to obtaining a posterior distribution conditional on observed data.

Usage

sbc(stanmodel, data, M, ..., save_progress, load_incomplete=FALSE)

### S3 method for class 'sbc'
plot(x, thin = 3, ...)

### S3 method for class 'sbc'
print(x, ...)

Arguments

- **stanmodel**: An object of `stanmodel-class` that is first created by calling the `stan_model` function.
- **data**: A named list or environment providing the data for the model, or a character vector for all the names of objects to use as data. This is the same format as in `stan` or `sampling`.
- **M**: The number of times to condition on draws from the prior predictive distribution.
- **...**: Additional arguments that are passed to `sampling`, such as `refresh = 0` when calling `sbc`. For the `plot` and `print` methods, the additional arguments are not used.
- **x**: An object produced by `sbc`.
- **thin**: An integer vector of length one indicating the thinning interval when plotting, which defaults to 3.
- **save_progress**: If a directory is provided, stanfit objects are saved to disk making it easy to resume a partial `sbc` run after interruption.
- **load_incomplete**: When `save_progress` is used, load whatever runs have been saved to disk and ignore argument `M`.

Details

This function assumes adherence to the following conventions in the underlying Stan program:

1. Realizations of the unknown parameters are drawn in the transformed data block of the Stan program and are postfixed with an underscore, such as `theta_`. These are considered the “true” parameters being estimated by the corresponding symbol declared in the parameters block, which should have the same name except for the trailing underscore, such as `theta`.
2. The realizations of the unknown parameters are then conditioned on when drawing from the prior predictive distribution, also in the transformed data block. There is no restriction on the symbol name that holds the realizations from the prior predictive distribution but for clarity, it should not end with a trailing underscore.
3. The realizations of the unknown parameters should be copied into a vector in the generated quantities block named `pars_`.
4. The realizations from the prior predictive distribution should be copied into an object (of the same type) in the generated quantities block named `y_`. Technically, this step is optional and could be omitted to conserve RAM, but inspecting the realizations from the prior predictive distribution is a good way to judge whether the priors are reasonable.
5. The generated quantities block must contain an integer array named `ranks_` whose only values are zero or one, depending on whether the realization of a parameter from the posterior distribution exceeds the corresponding “true” realization, such as `theta > theta_`. These are not actually "ranks" but can be used afterwards to reconstruct (thinned) ranks.
6. The generated quantities block may contain a vector named `log_lik` whose values are the contribution to the log-likelihood by each observation. This is optional but facilitates calculating Pareto k shape parameters to judge whether the posterior distribution is sensitive to particular observations.
Although the user can pass additional arguments to `sampling` through the ..., the following arguments are hard-coded and should not be passed through the ...:

1. `pars = "ranks_"` because nothing else needs to be stored for each posterior draw
2. `include = TRUE` to ensure that "ranks_" is included rather than excluded
3. `chains = 1` because only one chain is run for each integer less than \( M \)
4. `seed` because a sequence of seeds is used across the \( M \) runs to preserve independence across runs
5. `save_warmup = FALSE` because the warmup realizations are not relevant
6. `thin = 1` because thinning can and should be done after the Markov Chain is finished, as is done by the thin argument to the plot method in order to make the histograms consist of approximately independent realizations

Other arguments will take the default values used by `sampling` unless passed through the .... Specifying `refresh = 0` is recommended to avoid printing a lot of intermediate progress reports to the screen. It may be necessary to pass a list to the control argument of `sampling` with elements `adapt_delta` and / or `max_treedepth` in order to obtain adequate results.

Ideally, users would want to see the absence of divergent transitions (which is shown by the `print` method) and other warnings, plus an approximately uniform histogram of the ranks for each parameter (which are shown by the plot method). See the vignette for more details.

### Value

The `sbc` function outputs a list of S3 class "sbc", which contains the following elements:

1. `ranks` A list of \( M \) matrices, each with number of rows equal to the number of saved iterations and number of columns equal to the number of unknown parameters. These matrices contain the realizations of the `ranks_` object from the generated quantities block of the Stan program.
2. `Y` If present, a matrix of realizations from the prior predictive distribution whose rows are equal to the number of observations and whose columns are equal to \( M \), which are taken from the `y_` object in the generated quantities block of the Stan program.
3. `pars` A matrix of realizations from the prior distribution whose rows are equal to the number of parameters and whose columns are equal to \( M \), which are taken from the `pars_` object in the generated quantities block of the Stan program.
4. `pareto_k` A matrix of Pareto k shape parameter estimates or `NULL` if there is no `log_lik` symbol in the generated quantities block of the Stan program.
5. `sampler_params` A three-dimensional array that results from combining calls to `get_sampler_params` for each of the \( M \) runs. The resulting matrix has rows equal to the number of post-warmup iterations, columns equal to six, and \( M \) floors. The columns are named "accept_stat__", "stepsize__", "treedepth__", "n_leapfrog__", "divergent__", and "energy__". The most important of which is "divergent__", which should be all zeros and perhaps "treedepth__", which should only rarely get up to the value of `max_treedepth` passed as an element of the control list to `sampling` or otherwise defaults to 10.

The `print` method outputs the number of divergent transitions and returns `NULL` invisibly. The plot method returns a `ggplot` object with histograms whose appearance can be further customized.

"

---

set_cppo

Defunct function to set the compiler optimization level

Description

This function returns nothing and does nothing except throw a warning. See https://cran.r-project.org/doc/manuals/r-release/R-admin.html#Customizing-package-compilation for information on customizing the compiler options, but doing so should be unnecessary for normal usage.
Usage

\texttt{sflist2stanfit(...)}

Arguments

\textbf{...} \hspace{1cm} \text{Any input is ignored}

Value

An invisible NULL

\begin{quote}
\textbf{sflist2stanfit} \hspace{1cm} \textit{Merge a list of \texttt{stanfit} objects into one}
\end{quote}

Description

This function takes a list of \texttt{stanfit} objects and returns a consolidated \texttt{stanfit} object. The \texttt{stanfit} objects to be merged need to have the same configuration of iteration, warmup, and thin, besides being from the same model. This could facilitate some parallel usage of RStan. For example, if we call \texttt{stan} by parallel and it returns a list of \texttt{stanfit} objects, this function can be used to create one \texttt{stanfit} object from the list.

Usage

\texttt{sflist2stanfit(sflist)}

Arguments

\texttt{sflist} \hspace{1cm} A list of \texttt{stanfit} objects.

Value

An S4 object of \texttt{stanfit} consolidated from all the input \texttt{stanfit} objects.

Note

This function should be called in rare circumstances because \texttt{sampling} has a \texttt{cores} argument that allows multiple chains to be executed in parallel. However, if you need to depart from that, the best practice is to use \texttt{sflist2stanfit} on a list of \texttt{stanfit} objects created with the same seed but different \texttt{chain_id} (see example below). Using the same seed but different \texttt{chain_id} can make sure the random number generations for all chains are not correlated.

This function would do some check to see if the \texttt{stanfit} objects in the input list can be merged. But the check is not sufficient. So generally, it is the user’s responsibility to make sure the input is correct so that the merging makes sense.

The date in the new \texttt{stanfit} object is when it is merged.

\texttt{get_seed} function for the new consolidated \texttt{stanfit} object only returns the seed used in the first chain of the new object.
The sampler such as NUTS2 that is displayed in the printout by \texttt{print} is the sampler used for the first chain. The \texttt{print} method assumes the samplers are the same for all chains.

The included \texttt{stanmodel} object, which includes the compiled model, in the new \texttt{stanfit} object is from the first element of the input list.

fit <- sflist2stanfit(sflist1)
print(fit)
stopCluster(CL)
} # end example for Windows

## End(Not run)

---

**stan**

*Fit a model with Stan*

---

**Description**

Fit a model defined in the Stan modeling language and return the fitted result as an instance of stanfit.

**Usage**

```r
stan(file, model_name = "anon_model", model_code = ",", fit = NA,
    data = list(), pars = NA,
    chains = 4, iter = 2000, warmup = floor(iter/2), thin = 1,
    init = "random", seed = sample.int(.Machine$integer.max, 1),
    algorithm = c("NUTS", "HMC", "Fixed_param"),
    control = NULL, sample_file = NULL, diagnostic_file = NULL,
    save_dso = TRUE, verbose = FALSE, include = TRUE,
    cores = getOption("mc.cores", 1L),
    open_progress = interactive() && !isatty(stdout()) &&
        !identical(Sys.getenv("RSTUDIO"), "1"),
    ...,
    boost_lib = NULL, eigen_lib = NULL
)
```

**Arguments**

- **file**: The path to the Stan program to use. `file` should be a character string file name or a connection that R supports containing the text of a model specification in the Stan modeling language.

- **model_name**: A model may also be specified directly as a character string using the `model_code` argument, but we recommend always putting Stan programs in separate files with a .stan extension.

- **model_code**: The `stan` function can also use the Stan program from an existing stanfit object via the `fit` argument. When `fit` is specified, the `file` argument is ignored.
model_code A character string either containing the model definition or the name of a character string object in the workspace. This argument is used only if arguments file and fit are not specified.

fit An instance of S4 class stanfit derived from a previous fit; defaults to NA. If fit is not NA, the compiled model associated with the fitted result is re-used; thus the time that would otherwise be spent recompiling the C++ code for the model can be saved.

model_name A string to use as the name of the model; defaults to "anon_model". However, the model name will be derived from file or model_code (if model_code is the name of a character string object) if model_name is not specified. This is not a particularly important argument, although since it affects the name used in printed messages, developers of other packages that use rstan to fit models may want to use informative names.

data A named list or environment providing the data for the model, or a character vector for all the names of objects to use as data. See the **Passing data to Stan** section below.

pars A character vector specifying parameters of interest to be saved. The default is to save all parameters from the model. If include = TRUE, only samples for parameters named in pars are stored in the fitted results. Conversely, if include = FALSE, samples for all parameters except those named in pars are stored in the fitted results.

include Logical scalar defaulting to TRUE indicating whether to include or exclude the parameters given by the pars argument. If FALSE, only entire multidimensional parameters can be excluded, rather than particular elements of them.

iter A positive integer specifying the number of iterations for each chain (including warmup). The default is 2000.

warmup A positive integer specifying the number of warmup (aka burnin) iterations per chain. If step-size adaptation is on (which it is by default), this also controls the number of iterations for which adaptation is run (and hence these warmup samples should not be used for inference). The number of warmup iterations should be smaller than iter and the default is iter/2.

chains A positive integer specifying the number of Markov chains. The default is 4.

cores The number of cores to use when executing the Markov chains in parallel. The default is to use the value of the "mc.cores" option if it has been set and otherwise to default to 1 core. However, we recommend setting it to be as many processors as the hardware and RAM allow (up to the number of chains). See detectCores if you don’t know this number for your system.

thin A positive integer specifying the period for saving samples. The default is 1, which is usually the recommended value. Unless your posterior distribution takes up too much memory we do not recommend thinning as it throws away information. The tradition of thinning when running MCMC stems primarily from the use of samplers that require a large number of iterations to achieve the desired effective sample size. Because of the efficiency (effective samples per second) of Hamiltonian Monte Carlo, rarely should this be necessary when using Stan.
init Specification of initial values for all or some parameters. Can be the digit 0, the strings "0" or "random", a function that returns a named list, or a list of named lists:

init="random" (default): Let Stan generate random initial values for all parameters. The seed of the random number generator used by Stan can be specified via the seed argument. If the seed for Stan is fixed, the same initial values are used. The default is to randomly generate initial values between -2 and 2 on the unconstrained support. The optional additional parameter init_r can be set to some value other than 2 to change the range of the randomly generated inits.

init="0", init=0: Initialize all parameters to zero on the unconstrained support.

inits via list: Set initial values by providing a list equal in length to the number of chains. The elements of this list should themselves be named lists, where each of these named lists has the name of a parameter and is used to specify the initial values for that parameter for the corresponding chain.

inits via function: Set initial values by providing a function that returns a list for specifying the initial values of parameters for a chain. The function can take an optional parameter chain_id through which the chain_id (if specified) or the integers from 1 to chains will be supplied to the function for generating initial values. See the Examples section below for examples of defining such functions and using a list of lists for specifying initial values.

When specifying initial values via a list or function, any parameters for which values are not specified will receive initial values generated as described in the init="random" description above.

seed The seed for random number generation. The default is generated from 1 to the maximum integer supported by R on the machine. Even if multiple chains are used, only one seed is needed, with other chains having seeds derived from that of the first chain to avoid dependent samples. When a seed is specified by a number, as.integer will be applied to it. If as.integer produces NA, the seed is generated randomly. The seed can also be specified as a character string of digits, such as "12345", which is converted to integer.

Using R's set.seed function to set the seed for Stan will not work.

algorithm One of the sampling algorithms that are implemented in Stan. The default and preferred algorithm is "NUTS", which is the No-U-Turn sampler variant of Hamiltonian Monte Carlo (Hoffman and Gelman 2011, Betancourt 2017). Currently the other options are "HMC" (Hamiltonian Monte Carlo), and "Fixed_param". When "Fixed_param" is used no MCMC sampling is performed (e.g., for simulating with in the generated quantities block).

sample_file An optional character string providing the name of a file. If specified the draws for all parameters and other saved quantities will be written to the file. If not provided, files are not created. When the folder specified is not writable, tempdir() is used. When there are multiple chains, an underscore and chain number are appended to the file name.

diagnostic_file An optional character string providing the name of a file. If specified the diagnostics data for all parameters will be written to the file. If not provided, files
are not created. When the folder specified is not writable, `tempdir()` is used.

When there are multiple chains, an underscore and chain number are appended to the file name.

**save_dso**

Logical, with default `TRUE`, indicating whether the dynamic shared object (DSO) compiled from the C++ code for the model will be saved or not. If `TRUE`, we can draw samples from the same model in another R session using the saved DSO (i.e., without compiling the C++ code again). This parameter only takes effect if `fit` is not used; with `fit` defined, the DSO from the previous run is used. When `save_dso=TRUE`, the fitted object can be loaded from what is saved previously and used for sampling, if the compiling is done on the same platform, that is, same operating system and same architecture (32bits or 64bits).

**verbose**

`TRUE` or `FALSE`: flag indicating whether to print intermediate output from Stan on the console, which might be helpful for model debugging.

**control**

A named list of parameters to control the sampler’s behavior. It defaults to `NULL` so all the default values are used. First, the following are adaptation parameters for sampling algorithms. These are parameters used in Stan with similar names here.

- `adapt_engaged` (logical)
- `adapt_gamma` (double, positive, defaults to 0.05)
- `adapt_delta` (double, between 0 and 1, defaults to 0.8)
- `adapt_kappa` (double, positive, defaults to 0.75)
- `adapt_t0` (double, positive, defaults to 10)
- `adapt_init_buffer` (integer, positive, defaults to 75)
- `adapt_term_buffer` (integer, positive, defaults to 50)
- `adapt_window` (integer, positive, defaults to 25)

In addition, algorithm HMC (called 'static HMC' in Stan) and NUTS share the following parameters:

- `stepsize` (double, positive, defaults to 1) Note: this controls the initial stepsize only, unless `adapt_engaged=FALSE`.
- `stepsize_jitter` (double, [0,1], defaults to 0)
- `metric` (string, one of "unit_e", "diag_e", "dense_e", defaults to "diag_e")

For algorithm NUTS, we can also set:

- `max_treedepth` (integer, positive, defaults to 10)

For algorithm HMC, we can also set:

- `int_time` (double, positive)

For test_grad mode, the following parameters can be set:

- `epsilon` (double, defaults to 1e-6)
- `error` (double, defaults to 1e-6)

**open_progress**

Logical scalar that only takes effect if `cores > 1` but is recommended to be `TRUE` in interactive use so that the progress of the chains will be redirected to a file that is automatically opened for inspection. For very short runs, the user might prefer `FALSE`.

... Other optional parameters:
• chain_id (integer)
• init_r (double, positive)
• test_grad (logical)
• append_samples (logical)
• refresh (integer)
• save_warmup (logical)
• deprecated: enable_random_init (logical)

chain_id can be a vector to specify the chain_id for all chains or an integer. For
the former case, they should be unique. For the latter, the sequence of integers
starting from the given chain_id are used for all chains.

init_r is used only for generating random initial values, specifically when
init="random" or not all parameters are initialized in the user-supplied list
or function. If specified, the initial values are simulated uniformly from interval
[-init_r, init_r] rather than using the default interval (see the manual of
(cmd)Stan).

test_grad (logical). If test_grad=TRUE, Stan will not do any sampling. In-
stead, the gradient calculation is tested and printed out and the fitted stanfit
object is in test gradient mode. By default, it is FALSE.

append_samples (logical). Only relevant if sample_file is specified and is
an existing file. In that case, setting append_samples=TRUE will append the
samples to the existing file rather than overwriting the contents of the file.

refresh (integer) can be used to control how often the progress of the sam-
ping is reported (i.e. show the progress every refresh iterations). By default,
refresh = max(iter/10, 1). The progress indicator is turned off if refresh
<= 0.

Deprecated: enable_random_init (logical) being TRUE enables specifying
initial values randomly when the initial values are not fully specified from the
user.

save_warmup (logical) indicates whether to save draws during the warmup
phase and defaults to TRUE. Some memory related problems can be avoided by
setting it to FALSE, but some diagnostics are more limited if the warmup draws
are not stored.

boost_lib The path for an alternative version of the Boost C++ to use instead of the one in
the BH package.

eigen_lib The path for an alternative version of the Eigen C++ library to the one in RcppEigen.

Details

The stan function does all of the work of fitting a Stan model and returning the results as an instance
of stanfit. The steps are roughly as follows:

1. Translate the Stan model to C++ code. (stanc)
2. Compile the C++ code into a binary shared object, which is loaded into the current R session
(an object of S4 class stanmodel is created). (stan_model)
3. Draw samples and wrap them in an object of S4 class stanfit. (sampling)
The returned object can be used with methods such as print, summary, and plot to inspect and retrieve the results of the fitted model.

`stan` can also be used to sample again from a fitted model under different settings (e.g., different iter, data, etc.) by using the fit argument to specify an existing `stanfit` object. In this case, the compiled C++ code for the model is reused.

**Value**

An object of S4 class `stanfit`. However, if cores > 1 and there is an error for any of the chains, then the error(s) are printed. If all chains have errors and an error occurs before or during sampling, the returned object does not contain samples. But the compiled binary object for the model is still included, so we can reuse the returned object for another sampling.

**Passing data to Stan**

The data passed to `stan` are preprocessed before being passed to Stan. If data is not a character vector, the data block of the Stan program is parsed and R objects of the same name are searched starting from the calling environment. Then, if data is list-like but not a data.frame the elements of data take precedence. This behavior is similar to how a formula is evaluated by the `lm` function when data is supplied. In general, each R object being passed to Stan should be either a numeric vector (including the special case of a 'scalar') or a numeric array (matrix). The first exception is that an element can be a logical vector: TRUE’s are converted to 1 and FALSE’s to 0. An element can also be a data frame or a specially structured list (see details below), both of which will be converted into arrays in the preprocessing. Using a specially structured list is not encouraged though it might be convenient sometimes; and when in doubt, just use arrays.

This preprocessing for each element mainly includes the following:

1. Change the data of type from double to integer if no accuracy is lost. The main reason is that by default, R uses double as data type such as in a <- 3. But Stan will not read data of type int from real and it reads data from int if the data type is declared as real.
2. Check if there is NA in the data. Unlike BUGS, Stan does not allow missing data. Any NA values in supplied data will cause the function to stop and report an error.
3. Check data types. Stan allows only numeric data, that is, doubles, integers, and arrays of these. Data of other types (for example, characters and factors) are not passed to Stan.
4. Check whether there are objects in the data list with duplicated names. Duplicated names, if found, will cause the function to stop and report an error.
5. Check whether the names of objects in the data list are legal Stan names. If illegal names are found, it will stop and report an error. See (Cmd)Stan’s manual for the rules of variable names.
6. When an element is of type data.frame, it will be converted to matrix by function `data.matrix`.
7. When an element is of type list, it is supposed to make it easier to pass data for those declared in Stan code such as "vector[J] y1[I]" and "matrix[J,K] y2[I]". Using the latter as an example, we can use a list for `y2` if the list has "I" elements, each of which is an array (matrix) of dimension "J*K". However, it is not possible to pass a list for data declared such as "vector[K] y3[I,J]"; the only way for it is to use an array with dimension "I*J*K". In addition, technically a data.frame in R is also a list, but it should not be used for the purpose here since a data.frame will be converted to a matrix as described above.
Stan treats a vector of length 1 in R as a scalar. So technically if, for example, "array[1] real y;" is defined in the data block, an array such as "y = array(1.0, dim = 1)" in R should be used. This is also the case for specifying initial values since the same underlying approach for reading data from R in Stan is used, in which vector of length 1 is treated as a scalar.

In general, the higher the optimization level is set, the faster the generated binary code for the model runs, which can be set in a Makevars file. However, the binary code generated for the model runs fast by using a higher optimization level at the cost of longer times to compile the C++ code.

Examples

```r
## Not run:
#### example 1
library(rstan)
scode <- "
parameters {
    array[2] real y;
}
model {
    y[1] ~ normal(0, 1);
    y[2] ~ double_exponential(0, 2);
}
"
fit1 <- stan(model_code = scode, iter = 10, verbose = FALSE)
print(fit1)
fit2 <- stan(fit = fit1, iter = 10000, verbose = FALSE)

## using as.array on the stanfit object to get samples
a2 <- as.array(fit2)

## extract samples as a list of arrays
e2 <- extract(fit2, permuted = FALSE)

#### example 2
#### the result of this package is included in the package
excode <- '```
transformed data {
  array[20] real y;
  y[1] = 0.5796; y[2] = 0.2276; y[3] = -0.2959;
  y[10] = 0.3746; y[11] = 0.4773; y[12] = 0.1803;
  y[16] = 0.9459; y[17] = -0.382; y[18] = 0.7619;
  y[19] = 0.1006; y[20] = -1.7461;
}
parameters {
  real mu;
  real<lower=0, upper=10> sigma;
  vector[2] z[3];
  real<lower=0> alpha;
}
model {
  y ~ normal(mu, sigma);
  for (i in 1:3)
    z[i] ~ normal(0, 1);
  alpha ~ exponential(2);
}

exfit <- stan(model_code = excode, save_dso = FALSE, iter = 500)
print(exfit)
plot(exfit)

# define a function to generate initial values that can
# be fed to function stan's argument `init`
# function form 1 without arguments
initf1 <- function() {
  list(mu = 1, sigma = 4, z = array(rnorm(6), dim = c(3,2)), alpha = 1)
}
# function form 2 with an argument named `chain_id`
initf2 <- function(chain_id = 1) {
  # cat("chain_id =", chain_id, "\n")
  list(mu = 1, sigma = 4, z = array(rnorm(6), dim = c(3,2)), alpha = chain_id)
}

# generate a list of lists to specify initial values
n_chains <- 4
init_ll <- lapply(1:n_chains, function(id) initf2(chain_id = id))

exfit0 <- stan(model_code = excode, init = initf1)
stan(fit = exfit0, init = initf2)
stan(fit = exfit0, init = init_ll, chains = n_chains)
Description

Translate a model specification in Stan code to C++ code, which can then be compiled and loaded for sampling.

Usage

```r
stanc(file, model_code = '', model_name = "anon_model", verbose = FALSE,
      obfuscate_model_name = TRUE,
      allow_undefined = isTRUE(getOption("stanc.allow_undefined", FALSE)),
      allow_optimizations = isTRUE(getOption("stanc.allow_optimizations", FALSE)),
      standalone_functions = isTRUE(getOption("stanc.standalone_functions", FALSE)),
      use_opencl = isTRUE(getOption("stanc.use_opencl", FALSE)),
      warn_pedantic = isTRUE(getOption("stanc.warn_pedantic", FALSE)),
      warn_uninitialized = isTRUE(getOption("stanc.warn_uninitialized", FALSE)),
      isystem = c(if (!missing(file)) dirname(file), getwd())
)
```

```r
stanc_builder(file, isystem = c(dirname(file), getwd()),
              verbose = FALSE, obfuscate_model_name = FALSE,
              allow_undefined = isTRUE(getOption("stanc.allow_undefined", FALSE)),
              allow_optimizations = isTRUE(getOption("stanc.allow_optimizations", FALSE)),
              standalone_functions = isTRUE(getOption("stanc.standalone_functions", FALSE)),
              use_opencl = isTRUE(getOption("stanc.use_opencl", FALSE)),
              warn_pedantic = isTRUE(getOption("stanc.warn_pedantic", FALSE)),
              warn_uninitialized = isTRUE(getOption("stanc.warn_uninitialized", FALSE)))
```

Arguments

- **file**: A character string or a connection that R supports specifying the Stan model specification in Stan’s modeling language.
- **model_code**: Either a character string containing a Stan model specification or the name of a character string object in the workspace. This parameter is used only if parameter file is not specified, so it defaults to the empty string.
- **model_name**: A character string naming the model. The default is “anon_model”. However, the model name will be derived from file or model_code (if model_code is the name of a character string object) if model_name is not specified.
- **verbose**: Logical, defaulting to FALSE. If TRUE more intermediate information is printed during the translation procedure.
- **obfuscate_model_name**: Logical, defaulting to TRUE, indicating whether to use a randomly-generated character string for the name of the C++ class. This prevents name clashes when compiling multiple models in the same R session.
isystem
A character vector naming a path to look for file paths in file that are to be included within the Stan program named by file. See the Details section below.

allow_undefined
A logical scalar defaulting to FALSE indicating whether to allow Stan functions to be declared but not defined in file or model_code. If TRUE, then it is the caller’s responsibility to provide a function definition in another header file or linked shared object.

allow_optimizations
A logical scalar defaulting to FALSE indicating whether to allow level-1 compiler optimization to the Stan code.

standalone_functions
A logical scalar defaulting to FALSE indicating whether to generate the standalone functions C++ code.

use_opencl
A logical scalar defaulting to FALSE indicating whether to try to use matrix_cl signatures.

warn_pedantic
A logical scalar defaulting to FALSE indicating whether to emit warnings about common mistakes in Stan programs.

warn_uninitialized
A logical scalar defaulting to FALSE indicating whether emit warnings about uninitialized variables.

Details
The stanc_builder function supports the standard C++ convention of specifying something like #include "my_includes.txt" on an entire line within the file named by the file argument. In other words, stanc_builder would look for "my_includes.txt" in (or under) the directories named by the isystem argument and — if found — insert its contents verbatim at that position before calling stanc on the resulting model_code. This mechanism reduces the need to copy common chunks of code across Stan programs. It is possible to include such files recursively.

Note that line numbers referred to in parser warnings or errors refer to the postprocessed Stan program rather than file. In the case of a parser error, the postprocessed Stan program will be printed after the error message. Line numbers referred to in messages while Stan is executing also refer to the postprocessed Stan program which can be obtained by calling get_stancode.

Value
A list with named entries:

1. model_name Character string for the model name.
2. model_code Character string for the model’s Stan specification.
3. cppcode Character string for the model’s C++ code.
4. status Logical indicating success/failure (always TRUE) of translating the Stan code.

Note
Unlike R, in which variable identifiers may contain dots (e.g. a.1), Stan prohibits dots from occurring in variable identifiers. Furthermore, C++ reserved words and Stan reserved words may not be used for variable names; see the Stan User’s Guide for a complete list.

stanfit-class  

Class stanfit: fitted Stan model

Description

The components (slots) of a stanfit object and the various available methods are described below. When methods have their own more detailed documentation pages links are provided.

Objects from the Class

An object of class stanfit contains the output derived from fitting a Stan model as returned by the top-level function `stan` or the lower-level methods `sampling` and `vb` (which are defined on class `stanmodel`). Many methods (e.g., `print`, `plot`, `summary`) are provided for summarizing results and various access methods also allow the underlying data (e.g., simulations, diagnostics) contained in the object to be retrieved.
Slots

model_name: The model name as a string.

model_pars: A character vector of names of parameters (including transformed parameters and derived quantities).

parDims: A named list giving the dimensions for all parameters. The dimension for a scalar parameter is given as numeric(0).

mode: An integer indicating the mode of the fitted model. 0 indicates sampling mode, 1 indicates test gradient mode (no sampling is done), and 2 indicates error mode (an error occurred before sampling). Most methods for stanfit objects are useful only if mode=0.

sim: A list containing simulation results including the posterior draws as well as various pieces of metadata used by many of the methods for stanfit objects.

inits: The initial values (either user-specified or generated randomly) for all chains. This is a list with one component per chain. Each component is a named list containing the initial values for each parameter for the corresponding chain.

stan_args: A list with one component per chain containing the arguments used for sampling (e.g. iter, seed, etc.).

stanmodel: The instance of S4 class stanmodel.

date: A string containing the date and time the object was created.

.MISC: Miscellaneous helper information used for the fitted model. This is an object of type environment. Users rarely (if ever) need to access the contents of .MISC.

Methods

Printing, plotting, and summarizing:

show Print the default summary for the model.

print Print a customizable summary for the model. See print.stanfit.

plot Create various plots summarizing the fitted model. See plot,stanfit-method.

summary Summarize the distributions of estimated parameters and derived quantities using the posterior draws. See summary,stanfit-method.

get_posterior_mean Get the posterior mean for parameters of interest (using pars to specify a subset of parameters). Returned is a matrix with one column per chain and an additional column for all chains combined.

Extracting posterior draws:

extract Extract the draws for all chains for all (or specified) parameters. See extract.

as.array, as.matrix, as.data.frame Coerce the draws (without warmup) to an array, matrix or data frame. See as.array.stanfit.

As.mcmc.list Convert a stanfit object to an mcmc.list as in package coda. See As.mcmc.list.

get_logposterior Get the log-posterior at each iteration. Each element of the returned list is the vector of log-posterior values (up to an additive constant, i.e. up to a multiplicative constant on the linear scale) for a single chain. The optional argument inc_warmup (defaulting to TRUE) indicates whether to include the warmup period.
Diagnostics, log probability, and gradients:

get_sampler_params Obtain the parameters used for the sampler such as stepsize and treedepth. The results are returned as a list with one component (an array) per chain. The array has number of columns corresponding to the number of parameters used in the sampler and its column names provide the parameter names. Optional argument inc_warmup (defaulting to TRUE) indicates whether to include the warmup period.

get_adaptation_info Obtain the adaptation information for the sampler if NUTS was used. The results are returned as a list, each element of which is a character string with the info for a single chain.

log_prob Compute the log probability density (lp__) for a set of parameter values (on the unconstrained space) up to an additive constant. The unconstrained parameters are specified using a numeric vector. The number of parameters on the unconstrained space can be obtained using method get_num_upars. A numeric value is returned. See also the documentation in log_prob.

grad_log_prob Compute the gradient of log probability density function for a set of parameter values (on the unconstrained space) up to an additive constant. The unconstrained parameters are specified using a numeric vector with the length being the number of unconstrained parameters. A numeric vector is returned with the length of the number of unconstrained parameters and an attribute named log_prob being the lp__. See also the documentation in grad_log_prob.

get_num_upars Get the number of unconstrained parameters of the model. The number of parameters for a model is not necessarily equal to this number of unconstrained parameters. For example, when a parameter is specified as a simplex of length K, the number of unconstrained parameters is K-1.

unconstrain_pars Transform the parameters to unconstrained space. The input is a named list as for specifying initial values for each parameter. A numeric vector is returned. See also the documentation in unconstrain_pars.

constrain_pars Get the parameter values from their unconstrained space. The input is a numeric vector. A list is returned. This function is contrary to unconstrain_pars. See also the documentation in constrain_pars.

Metadata and miscellaneous:

gget_stancode Get the Stan code for the fitted model as a string. The result can be printed in a readable format using cat.

gget_stanmodel Get the object of S4 class stanmodel of the fitted model.

gget_elapsed_time Get the warmup time and sample time in seconds. A matrix of two columns is returned with each row containing the warmup and sample times for one chain.

gget_inits, iter = NULL Get the initial values for parameters used in sampling all chains. The returned object is a list with the same structure as the inits slot described above. If object@mode=2 (error mode) an empty list is returned. If iter is not NULL, then the draw from that iteration is returned for each chain rather than the initial state.

gget_cpp_mode Get the optimization mode used for compilation. The returned string is one of "fast", "presentation2", "presentation1", and "debug".

gget_seed Get the (P)RNG seed used. When the fitted object is empty (mode=2), NULL might be returned. In the case that the seeds for all chains are different, use gget_seeds.
get_seeds  Get the seeds used for all chains. When the fitted object is empty (mode=2), NULL might be returned.

stanmodel-class

Class representing model compiled from C++

Description

A stanmodel object represents the model compiled from C++ code. The sampling method defined in this class may be used to draw samples from the model and optimizing method is for obtaining a point estimate by maximizing the log-posterior.

Objects from the Class

Instances of stanmodel are usually created by calling function stan_model or function stan.

Slots

- model_name: The model name, an object of type character.
- model_code: The Stan model specification, an object of type character.
- model_cpp: Object of type list that includes the C++ code for the model.
- mk_cppmodule: A function to return a RCpp module. This function will be called in function sampling and optimizing with one argument (the instance of stanmodel itself).
- dso: Object of S4 class cxxdso. The container for the dynamic shared objects compiled from the C++ code of the model, returned from function cxxfunction in package inline.

Methods

- show signature(object = "stanmodel"): print the Stan model specification.
- vb signature(object = "stanmodel"): use the variational Bayes algorithms.
- sampling signature(object = "stanmodel"): draw samples for the model (see sampling).
- optimizing signature(object = "stanmodel"): obtain a point estimate by maximizing the posterior (see optimizing).
- get_cppcode signature(object = "stanmodel"): returns the C++ code for the model as a character string. This is part of the C++ code that is compiled to the dynamic shared object for the model.
- get_stancode signature(object = "stanmodel"): returns the Stan code for the model as a character string
- get_cxxflags signature(object = "stanmodel"): return the CXXFLAGS used for compiling the model. The returned string is like CXXFLAGS = -O3.

Note

Objects of class stanmodel can be saved for use across R sessions only if save_dso = TRUE is set during calling functions that create stanmodel objects (e.g., stan and stan_model).

Even if save_dso = TRUE, the model cannot be loaded on a platform (operating system, 32 bits or 64 bits, etc.) that differs from the one on which it was compiled.

Examples

showClass("stanmodel")

---

**stan_demo**  
Demonstrate examples included in Stan

Description

Stan includes a variety of examples and most of the BUGS example models that are translated into Stan modeling language. One example is chosen from a list created from matching user input and gets fitted in the demonstration.

Usage

```r
stan_demo(model = character(0),  
          method = c("sampling", "optimizing", "meanfield", "fullrank"), ...)  
```

Arguments

- **model**  
  A character string for model name to specify which model will be used for demonstration. The default is an empty string, which prompts the user to select one the available models. If `model = \emptyset`, a character vector of all models is returned without any user intervention. If `model = i` where `i > 0`, then the ith available model is chosen without user intervention, which is useful for testing.

- **method**  
  Whether to call `sampling` (the default), `optimizing`, or one of the variants of `vb` for the demonstration

- ...  
  Further arguments passed to method.

Value

An S4 object of `stanfit`, unless `model = \emptyset`, in which case a character vector of paths to available models is returned.

fit1 <- stan_demo(1) # run model_names[1]

## End(Not run)
```

---

**stan_model**  
*Construct a Stan model*

**Description**

Construct an instance of S4 class `stanmodel` from a model specified in Stan’s modeling language. A `stanmodel` object can then be used to draw samples from the model. The Stan program (the model expressed in the Stan modeling language) is first translated to C++ code and then the C++ code for the model plus other auxiliary code is compiled into a dynamic shared object (DSO) and then loaded. The loaded DSO for the model can be executed to draw samples, allowing inference to be performed for the model and data.

**Usage**

```r
stan_model(
  file, model_name = "anon_model",
  model_code = "", stanc_ret = NULL,
  boost_lib = NULL, eigen_lib = NULL,
  save_dso = TRUE, verbose = FALSE,
  auto_write = rstan_options("auto_write"),
  obfuscate_model_name = TRUE,
  allow_undefined = isTRUE(getOption("stanc.allow_undefined", FALSE)),
  allow_optimizations = isTRUE(getOption("stanc.allow_optimizations", FALSE)),
  standalone_functions = isTRUE(getOption("stanc.standalone_functions", FALSE)),
  use_opencl = isTRUE(getOption("stanc.use_opencl", FALSE)),
  warn_pedantic = isTRUE(getOption("stanc.warn_pedantic", FALSE)),
  warn_uninitialized = isTRUE(getOption("stanc.warn_uninitialized", FALSE)),
  includes = NULL,
  isystem = c(if (!missing(file)) dirname(file), getwd()))
```

**Arguments**

- `file`  
  A character string or a connection that R supports specifying the Stan model specification in Stan’s modeling language.

- `model_name`  
  A character string naming the model; defaults to "anon_model". However, the model name will be derived from `file` or `model_code` (if `model_code` is the name of a character string object) if `model_name` is not specified.

- `model_code`  
  Either a character string containing the model specification or the name of a character string object in the workspace. This is an alternative to specifying the model via the `file` or `stanc_ret` arguments.
`stan_model`

- **stanc_ret**: A named list returned from a previous call to the `stanc` function. The list can be used to specify the model instead of using the `file` or `model_code` arguments.
- **boost_lib**: The path to a version of the Boost C++ library to use instead of the one in the BH package.
- **eigen_lib**: The path to a version of the Eigen C++ library to use instead of the one in the RcppEigen package.
- **save_dso**: Logical, defaulting to `TRUE`, indicating whether the dynamic shared object (DSO) compiled from the C++ code for the model will be saved or not. If `TRUE`, we can draw samples from the same model in another R session using the saved DSO (i.e., without compiling the C++ code again).
- **verbose**: Logical, defaulting to `FALSE`, indicating whether to report additional intermediate output to the console, which might be helpful for debugging.
- **auto_write**: Logical, defaulting to the value of `rstan_options("auto_write")`, indicating whether to write the object to the hard disk using `saveRDS`. Although this argument is `FALSE` by default, we recommend calling `rstan_options("auto_write" = TRUE)` in order to avoid unnecessary recompilations. If `file` is supplied and its `dirname` is writable, then the object will be written to that same directory, substituting a `.rds` extension for the `.stan` extension. Otherwise, the object will be written to the `tempdir`.
- **obfuscate_model_name**: A logical scalar that is `TRUE` by default and passed to `stanc`.
- **allow_undefined**: A logical scalar that is `FALSE` by default and passed to `stanc`.
- **allow_optimizations**: A logical scalar that is `FALSE` by default and passed to `stanc`.
- **standalone_functions**: A logical scalar that is `FALSE` by default and passed to `stanc`.
- **use_opencl**: A logical scalar that is `FALSE` by default and passed to `stanc`.
- **warn_pedantic**: A logical scalar that is `FALSE` by default and passed to `stanc`.
- **warn_uninitialized**: A logical scalar that is `FALSE` by default and passed to `stanc`.
- **includes**: If not NULL (the default), then a character vector of length one (possibly containing one or more "\n") of the form `'#include "full/path/to/my_header.hpp"'`, which will be inserted into the C++ code in the model's namespace and can be used to provide definitions of functions that are declared but not defined in `file` or `model_code` when `allow_undefined = TRUE`.
- **isystem**: A character vector naming a path to look for file paths in `file` that are to be included within the Stan program named by `file`. See the Details section below.

**Details**

If a previously compiled `stanmodel` exists on the hard drive, its validity is checked and then returned without recompiling. The most common form of invalidity seems to be Stan code that ends with a `}` rather than a blank line, which causes the hash checker to think that the current model is different.
than the one saved on the hard drive. To avoid reading previously compiled stanmodels from the hard drive, supply the stanc_ret argument rather than the file or model_code arguments.

There are three ways to specify the model's code for stan_model:

1. parameter model_code: a character string containing the Stan model specification,
2. parameter file: a file name (or a connection) from which to read the Stan model specification, or
3. parameter stanc_ret: a list returned by stanc to be reused.

Value

An instance of S4 class stanmodel that can be passed to the sampling, optimizing, and vb functions.

References

See Also

stanmodel for details on the class.
sampling, optimizing, and vb, which take a stanmodel object as input, for estimating the model parameters.

More details on Stan, including the full user's guide and reference manual, can be found at https://mc-stan.org/.

Examples

```r
## Not run:
stancode <- 'data {real y_mean;} parameters {real y;} model {y ~ normal(y_mean,1);}'
mod <- stan_model(model_code = stancode, verbose = TRUE)
fit <- sampling(mod, data = list(y_mean = 0))
fit2 <- sampling(mod, data = list(y_mean = 5))
## End(Not run)
```

---

**stan_rdump**

Dump the data for a Stan model to R dump file in the limited format that Stan can read.

**Description**

This function takes a vector of names of R objects and outputs text representations of the objects to a file or connection. The file created by stan_rdump is typically used as data input of the Stan package (https://mc-stan.org/) or sourced into another R session. The usage of this function is very similar to dump in R.
Usage

stan_rdump(list, file = "", append = FALSE, 
envir = parent.frame(),
width = options("width")$width,
quiet = FALSE)

Arguments

list         A vector of character string: the names of one or more R objects to be dumped. 
             See the note below.
file         Either a character string naming a file or a connection. "" indicates output to the 
             console.
append       Logical: if TRUE and file is a character string, output will be appended to file; 
             otherwise, it will overwrite the contents of file.
envir        The environment to search for objects.
width        The width for maximum characters on a line. The output is broken into lines 
             with width.
quiet        Whether to suppress warning messages that would appear when a variable is 
             not found or not supported for dumping (not being numeric or it would not be 
             converted to numeric) or a variable name is not allowed in Stan.

Value

An invisible character vector containing the names of the objects that were dumped.

Note

stan_rdump only dumps numeric data, which first can be a scalar, vector, matrix, or (multidimensional) array. Additional types supported are logical (TRUE and FALSE), factor, data.frame and a specially structured list.

The conversion for logical variables is to map TRUE to 1 and FALSE to 0. For factor variable, function as.integer is used to do the conversion (If we want to transform a factor f to approximately its original numeric values, see the help of function factor and do the transformation before calling stan_rdump). In the case of data.frame, function data.matrix is applied to the data frame before dumping. See the notes in stan for the specially structured list, which will be converted to array before dumping.

stan_rdump will check whether the names of objects are legal variable names in Stan. If an illegal name is found, data will be dumped with a warning. However, passing the name checking does not necessarily mean that the name is legal. More details regarding rules of variable names in Stan can be found in Stan's manual.

If objects with specified names are not found, a warning will be issued.

### stan_version

**Obtain the version of Stan**

---

#### Description

The `stan_version` function returns the version of Stan used in the current installation of RStan.

#### Usage

```r
stan_version()
```

#### Value

A character string giving the version of Stan used in this version of RStan.

#### References

#### See Also

- `stan`
- `stan_model`

#### Examples

```r
stan_version()
```
Summary method for stanfit objects

Summary method for stanfit objects

Description

Summarize the distributions of estimated parameters and derived quantities using the posterior draws.

Usage

```r
## S4 method for signature 'stanfit'
summary(object, pars, probs = c(0.025, 0.25, 0.50, 0.75, 0.975),
         use_cache = TRUE, ...)
```

Arguments

- `object`: An instance of class `stanfit`.
- `pars`: A character vector of parameter names. Defaults to all parameters as well as the log-posterior (`lp__`).
- `probs`: A numeric vector of quantiles of interest. The default is `c(0.025, 0.25, 0.5, 0.75, 0.975)`. 
- `use_cache`: Logical, defaulting to `TRUE`. When `use_cache=TRUE` the summary quantities for all parameters are computed and cached for future use. Setting `use_cache=FALSE` can be used to avoid performing the summary computations for all parameters if `pars` is given as some specific parameters.
- `...`: Currently unused.

Value

The `summary` method returns a named list with elements `summary` and `c_summary`, which contain summaries for for all chains merged and individual chains, respectively. Included in the summaries are quantiles, means, standard deviations (sd), effective sample sizes (n_eff), and split Rhats (the potential scale reduction derived from all chains after splitting each chain in half and treating the halves as chains). For the summary of all chains merged, Monte Carlo standard errors (se_mean) are also reported.

See Also

- `monitor`, which computes similar summaries but accepts an array of MCMC draws as its input rather than a `stanfit` object.
- The RStan vignettes for more example usage.
Examples

```r
## Not run:
ecode <- '
parameters {
  array[2] real<lower=0> y;
}
model {
  y ~ exponential(1);
}
',
fit <- stan(model_code = ecode)
s <- summary(fit, probs = c(0.1, 0.9))
s$summary # all chains merged
s$c_summary # individual chains

## End(Not run)
```

## Description

Draw the traceplot corresponding to one or more Markov chains, providing a visual way to inspect sampling behavior and assess mixing across chains and convergence.

## Usage

```r
## S4 method for signature 'stanfit'
traceplot(object, pars, include = TRUE, unconstrain = FALSE, inc_warmup = FALSE, window = NULL, nrow = NULL, ncol = NULL, ...)
```

## Arguments

- **object**: An instance of class `stanfit`.
- **pars**: A character vector of parameter names. Defaults to all parameters or the first 10 parameters (if there are more than 10).
- **include**: Should the parameters given by the `pars` argument be included (the default) or excluded from the plot? Only relevant if `pars` is not missing.
- **inc_warmup**: TRUE or FALSE, indicating whether the warmup sample are included in the trace plot; defaults to FALSE.
- **window**: A vector of length 2. Iterations between `window[1]` and `window[2]` will be shown in the plot. The default is to show all iterations if `inc_warmup` is TRUE and all iterations from the sampling period only if `inc_warmup` is FALSE. If `inc_warmup` is FALSE the iterations specified in `window` should not include iterations from the warmup period.
unconstrain  Should parameters be plotted on the unconstrained space? Defaults to FALSE.
nrow,ncol  Passed to facet_wrap.
...  Optional arguments to pass to geom_path (e.g. size, linetype, alpha, etc.).

Value
A ggplot object that can be further customized using the ggplot2 package.

Methods
traceplot signature(object = "stanfit") Plot the sampling paths for all chains.

trace + scale_color_discrete() + theme(legend.position = "top")

## End(Not run)

---

vb Run Stan’s variational algorithm for approximate posterior sampling

Description

Approximately draw from a posterior distribution using variational inference.
This is still considered an experimental feature. We recommend calling stan or sampling for final inferences and only using vb to get a rough idea of the parameter distributions.

Usage

## S4 method for signature 'stanmodel'

vb(object, data = list(), pars = NA, include = TRUE, 
    seed = sample.int(.Machine$integer.max, 1), 
    init = 'random', check_data = TRUE, 
    sample_file = tempfile(fileext = '.csv'), 
    algorithm = c("meanfield", "fullrank"), 
    importance_resampling = FALSE, keep_every = 1, 
    ...
)

Arguments

object An object of class stanmodel.
data A named list or environment providing the data for the model or a character vector for all the names of objects used as data. See the Passing data to Stan section in stan.
pars If not NA, then a character vector naming parameters, which are included in the output if include = TRUE and excluded if include = FALSE. By default, all parameters are included.
include Logical scalar defaulting to TRUE indicating whether to include or exclude the parameters given by the pars argument. If FALSE, only entire multidimensional parameters can be excluded, rather than particular elements of them.
seed
The seed for random number generation. The default is generated from 1 to the maximum integer supported by R on the machine. Even if multiple chains are used, only one seed is needed, with other chains having seeds derived from that of the first chain to avoid dependent samples. When a seed is specified by a number, as.integer will be applied to it. If as.integer produces NA, the seed is generated randomly. The seed can also be specified as a character string of digits, such as "12345", which is converted to integer.

init
Initial values specification. See the detailed documentation for the init argument in stan.

check_data
Logical, defaulting to TRUE. If TRUE the data will be preprocessed; otherwise not. See the Passing data to Stan section in stan.

sample_file
A character string of file name for specifying where to write samples for all parameters and other saved quantities. This defaults to a temporary file.

algorithm
Either "meanfield" (the default) or "fullrank", indicating which variational inference algorithm is used. The "meanfield" option uses a fully factorized Gaussian for the approximation whereas the fullrank option uses a Gaussian with a full-rank covariance matrix for the approximation. Details and additional references are available in the Stan manual.

importance_resampling
Logical scalar (defaulting to FALSE) indicating whether to do importance resampling to adjust the draws at the optimum to be more like draws from the posterior distribution

keep_every
Integer scalar (defaulting to 1) indicating the interval by which to thin the draws when importance_resampling = TRUE

... Other optional parameters:

• iter (positive integer), the maximum number of iterations, defaulting to 10000.
• grad_samples (positive integer), the number of samples for Monte Carlo estimate of gradients, defaulting to 1.
• elbo_samples (positive integer), the number of samples for Monte Carlo estimate of ELBO (objective function), defaulting to 100. (ELBO stands for "the evidence lower bound").
• eta (double), positive stepsize weighting parameter for variational inference but is ignored if adaptation is engaged, which is the case by default.
• adapt_engaged (logical), a flag indicating whether to automatically adapt the stepsize, defaulting to TRUE.
• tol_rel_obj (positive double), the convergence tolerance on the relative norm of the objective, defaulting to 0.01.
• eval_elbo (positive integer), evaluate ELBO every Nth iteration, defaulting to 100.
• output_samples (positive integer), number of posterior samples to draw and save, defaults to 1000.
• adapt_iter (positive integer), the maximum number of iterations to adapt the stepsize, defaulting to 50. Ignored if adapt_engaged = FALSE.

Refer to the manuals for both CmdStan and Stan for more details.
Value
An object of `stanfit-class`.

Methods

```r
vb signature(object = "stanmodel")
```

Call Stan’s variational Bayes methods for the model defined by S4 class `stanmodel` given the data, initial values, etc.

References
