Package ‘secr’

October 18, 2023

Type Package
Title Spatially Explicit Capture-Recapture
Version 4.6.4
Date 2023-10-18
Description Functions to estimate the density and size of a spatially distributed animal population sampled with an array of passive detectors, such as traps, or by searching polygons or transects. Models incorporating distance-dependent detection are fitted by maximizing the likelihood. Tools are included for data manipulation and model selection.

Depends R (>= 3.5.0), methods
Imports abind, graphics, grDevices, MASS, mgcv, nlme, parallel, raster (>= 3.5-15), Rcpp (>= 0.12.14), RcppNumerical, RcppParallel (>= 5.1.1), sf, stats, stringr, terra (>= 1.5-12), tools, utils
Suggests gdistance, igraph, knitr, readxl, rmarkdown, sp, spatstat (>= 3.0-2), spatstat.geom, spatstat.random, spsurvey (>= 5.3.0), testthat

Spatially explicit capture-recapture is a set of methods for studying marked animals distributed in space. Data comprise the locations of detectors (traps, searched areas, etc. described in an object of class ‘traps’), and the detection histories of individually marked animals. Individual histories are
Models for population density (animals per hectare) and detection are defined in \texttt{secr} using symbolic formula notation. Density models may include spatial or temporal trend. Possible predictors for detection probability include both pre-defined variables (t, b, etc.) corresponding to ‘time’, ‘behaviour’ and other effects), and user-defined covariates of several kinds. Habitat is distinguished from nonhabitat with an object of class ‘mask’.

Models are fitted in \texttt{secr} by maximizing either the full likelihood or the likelihood conditional on the number of individuals observed (n). Conditional likelihood models are limited to homogeneous Poisson density, but allow continuous individual covariates for detection. A model fitted with \texttt{secr.fit} is an object of class \texttt{secr}. Generic methods (plot, print, summary, etc.) are provided for each object class.

A link at the bottom of each help page takes you to the help index. Several vignettes complement the help pages:

- **General interest**
  - \texttt{secr-overview.pdf} general introduction
  - \texttt{secr-datainput.pdf} data formats and input functions
  - \texttt{secr-version4.pdf} changes in secr 4.0
  - \texttt{secr-manual.pdf} consolidated help pages
  - \texttt{secr-tutorial.pdf} introductory tutorial
  - \texttt{secr-habitatmasks.pdf} buffers and habitat masks
  - \texttt{secr-spatialdata.pdf} using spatial data
  - \texttt{secr-models.pdf} linear models in \texttt{secr}
  - \texttt{secr-troubleshooting.pdf} problems with \texttt{secr.fit}, including speed issues

- **More specialised topics**
  - \texttt{secr-densitysurfaces.pdf} modelling density surfaces
  - \texttt{secr-finitemixtures.pdf} mixture models for individual heterogeneity
  - \texttt{secr-markresight.pdf} mark-resight data and models
  - \texttt{secr-multisession.pdf} multi-session capthist objects and models
  - \texttt{secr-noneuclidean.pdf} non-Euclidean distances
  - \texttt{secr-parameterisations.pdf} alternative parameterisations sigmak, a0
  - \texttt{secr-polygondetectors.pdf} using polygon and transect detector types
  - \texttt{secr-sound.pdf} analysing data from microphone arrays
  - \texttt{secr-varyingeffort.pdf} variable effort in SECR models

The datasets \texttt{captdata} and \texttt{ovenbird} include examples of fitted models. For models fitted to other datasets see \texttt{secr-version4.pdf} Appendix 2.

Add-on packages extend the capability of \texttt{secr} and are documented separately. \texttt{secrlinear} enables the estimation of linear density (e.g., animals per km) for populations in linear habitats such as stream networks (\texttt{secrlinear-vignette.pdf}). \texttt{secredesign} enables the assessment of alternative study designs by Monte Carlo simulation; scenarios may differ in detector (trap) layout, sampling intensity, and other characteristics (\texttt{secredesign-vignette.pdf}). \texttt{ipsecr} fits some awkward models (e.g., for single-catch traps) by simulation and inverse prediction (\texttt{ipsecr-vignette.pdf}). \texttt{openCR} fits open population models, both non-spatial and spatial (\texttt{openCR-vignette.pdf}).
The analyses in secr extend those available in the software Density (see www.otago.ac.nz/density/ for the most recent version of Density). Help is available on the ‘DENSITY i secr’ forum at www.phidot.org and the Google group secrgroup. Feedback on the software is also welcome, including suggestions for additional documentation or new features consistent with the overall design.

**addCovariates**  
*Add Covariates to Mask or Traps*

**Description**
Tools to construct spatial covariates for existing mask or traps objects from a spatial data source.

**Usage**
```
addCovariates(object, spatialdata, columns = NULL, strict = FALSE, replace = FALSE)
```

**Arguments**
- **object**: mask, traps or popn object
- **spatialdata**: spatial data source (see Details)
- **columns**: character vector naming columns to include (all by default)
- **strict**: logical; if TRUE a check is performed for points in object that lie outside spatialdata (mask data sources only)
- **replace**: logical; if TRUE then covariates with duplicate names are replaced; otherwise a new column is added
addCovariates

Details

The goal is to obtain the value(s) of one or more spatial covariates for each point (i.e. row) in object. The procedure depends on the data source spatialdata, which may be either a spatial coverage (raster or polygon) or an object with covariate values at points (another mask or traps object). In the first case, an overlay operation is performed to find the pixel or polygon matching each point. In the second case, a search is conducted for the closest point in spatialdata.

If spatialdata is a character value then it is interpreted as the name of a polygon shape file (excluding ".shp").

If spatialdata is a SpatialPolygonsDataFrame, SpatialGridDataFrame or 'sf' object from sf then it will be used in an overlay operation as described.

If package terra has been installed then spatialdata may also be a RasterLayer from package raster or SpatRaster from terra. If provided counts should be a single name that will be used for the values (otherwise 'raster' will be used).

If spatialdata is a mask or traps object then it is searched for the closest point to each point in object, and covariates are drawn from the corresponding rows in covariates(spatialdata). By default (strict = FALSE), values are returned even when the points lie outside any cell of the mask.

Value

An object of the same class as object with new or augmented covariates attribute. Column names and types are derived from the input.

Warning

Use of a SpatialGridDataFrame for spatialdata is untested.

Examples

```r
## In the Lake Station skink study (see ?skink), habitat covariates were
## measured only at trap sites. Here we extrapolate to a mask, taking
## values for each mask point from the nearest trap.
LSmask <- make.mask(LStraps, buffer = 30, type = "trapbuffer")
tempmask <- addCovariates(LSmask, LStraps)
## show first few lines
head(covariates(tempmask))
```
addSightings  Mark-resight Data

Description

Add sighting data on unmarked individuals and/or unidentified marked individuals to an existing capthist object.

Usage

addSightings(capthist, unmarked = NULL, nonID = NULL, uncertain = NULL, verify = TRUE, ...)

Arguments

capthist  secr capthist object
unmarked  matrix or list of matrices of sightings of unmarked animals, Tu, or file name (see Details)
nonID  matrix or list of matrices of unidentified sightings of marked animals, Tm, or file name (see Details)
uncertain  matrix or list of matrices of uncertain sightings, Tn, or file name (see Details)
verify  logical; if TRUE then the resulting capthist object is checked with verify
...
other arguments passed to read.table

Details

The capthist object for mark-resight analysis comprises distinct marking and sighting occasions, defined in the markocc attribute of traps(capthist). Add this attribute to traps(capthist) with markocc before using ‘addSightings’. See also read.traps and read.capthist.

Mark-resight data may be binary (detector type ‘proximity’) or counts (detector types ‘count’, ‘polygon’ or ‘transect’). The detector type is an attribute of traps(capthist). Values in unmarked and nonID should be whole numbers, and may be greater than 1 even for binary proximity detectors because multiple animals may be detected simultaneously at one place.

Arguments unmarked, nonID, uncertain provide data for attributes ‘Tu’, ‘Tm’, ‘Tn’ respectively. They may take several forms

- a single integer, the sum of all counts*
- a matrix of the count on each occasion at each detector (dimensions K x S, where K is the number of detectors and S is the total number of occasions). Columns corresponding to marking occasions should be all-zero.
- for multi-session data, a list with components as above
**addSightings**

- a character value with the name of a text file containing the data; the file will be read with `read.table`. The ... argument allows some control over how the file is read. The data format comprises at least S+1 columns. The first is a session identifier used to split the file when the data span multiple sessions; it should be constant for a single-session capthist. The remaining S columns contain the counts for occasions 1:S, one row per detector. Further columns may be present; they are ignored at present.

* although this is convenient, the full matrix of counts provides more flexibility (e.g., when you wish to subset by occasion), and enables modelling of variation across detectors and occasions.

**Value**

A capthist object with the same structure as the input, but with new sighting-related attributes Tu (sightings of unmarked animals) and/or Tm (unidentified sightings of marked animals). Input values, including NULL, overwrite existing values.

**Warning**

** Mark-resight data formats and models are experimental and subject to change **

**See Also**

markocc, read.capthist, read.traps, sim.resight, Tm, Tu, Tn, secr-markresight.pdf

**Examples**

```r
## construct capthist object MRCH from text files provided in 
## 'extdata' folder, assigning attribute 'markocc' and add unmarked 
## and marked sightings from respective textfiles

datadir <- system.file("extdata", package = "secr")
captfile <- paste0(datadir, "/MRCHcapt.txt")
trapfile <- paste0(datadir, "/MRCHtrap.txt")
Tufile <- paste0(datadir, "/Tu.txt")
Tmfile <- paste0(datadir, "/Tm.txt")

MRCH <- read.capthist(captfile, trapfile, detector = c("multi", rep("proximity",4)), markocc = c(1,0,0,0,0))
MRCH1 <- addSightings(MRCH, Tufile, Tmfile)

## alternatively (ignoring marked, not ID sightings)

MRCH <- read.capthist(captfile, trapfile, detector = c("multi", rep("proximity",4)), markocc = c(1,0,0,0,0))
Tu <- read.table(Tufile)[,-1] # drop session column
MRCH2 <- addSightings(MRCH, unmarked = Tu)
summary(MRCH2)
```
addTelemetry

Combine Telemetry and Detection Data

Description

Animal locations determined by radiotelemetry can be used to augment capture–recapture data. The procedure in secr is first to form a capthist object containing the telemetry data and then to combine this with true capture–recapture data (e.g. detections from hair-snag DNA) in another capthist object. secr.fit automatically detects the telemetry data in the new object.

Usage

addTelemetry(detectionCH, telemetryCH, type = c('concurrent', 'dependent', 'independent'),
collapsetelemetry = TRUE, verify = TRUE)

xy2CH(CH, inflation = 1e-08)
telemetrytype(object) <- value
telemetrytype(object, ...)

Arguments

detectionCH single-session capthist object, detector type ‘single’, ‘multi’, ‘proximity’ or ‘count’
telemetryCH single-session capthist object, detector type ‘telemetryonly’
type character (see Details)
collapsetelemetry logical; if TRUE then telemetry occasions are collapsed to one
verify logical; if TRUE then verify.capthist is called on the output
CH capthist object with telemetryxy attribute
inflation numeric tolerance for polygon
object secr traps object
value character telemetry type replacement value
...
other arguments

Details

It is assumed that a number of animals have been radiotagged, and their telemetry data (xy-coordinates) have been input to telemetryCH, perhaps using read.capthist with detector = "telemetryonly" and fmt = "XY", or with read.telemetry.

A new capthist object is built comprising all the detection histories in detectionCH, plus empty (all-zero) histories for every telemetered animal not in detectionCH. Telemetry is associated with new
sampling occasions and a new detector (nominally at the same point as the first in detectionCH).
The number of telemetry fixes of each animal is recorded in the relevant cell of the new capthist
object (CH[i, s, K+1] for animal i and occasion s if there were K detectors in detectionCH).
The new sampling occasion(s) are assigned the detector type ‘telemetry’ in the traps attribute of
the output capthist object, and the traps attribute telemetrytype is set to the value provided. The
telemetry type may be “independent” (no matching of individuals in captured and telemetered sam-
plies), “dependent” (telemetered animals are a subset of captured animals) or “concurrent” (histories
may be capture-only, telemetry-only or both capture and telemetry).
The telemetry locations are carried over from telemetryCH as attribute ‘xylist’ (each component of
xlist holds the coordinates of one animal; use telemetryxy to extract).
The default behaviour of ‘addTelemetry’ is to automatically collapse all telemetry occasions into
one. This is computationally more efficient than the alternative, but closes off some possible models.
x2CH partly reverses addTelemetry: the location information in the telemetryxy attribute is con-
verted back to a capthist with detector type ‘telemetry’.

Value

A single-session capthist object with the same detector type as detectionCH, but possibly with
empty rows and an ‘telemetryxy’ attribute.

Note

Telemetry provides independent data on the location and presence of a sample of animals. These
animals may be missed in the main sampling that gives rise to detectionCH i.e., they may have
all-zero detection histories.
The ‘telemetry’ detector type is used for telemetry occasions in a combined dataset.

See Also

capthist, make.telemetry, read.telemetry, telemetryxy telemetered

Examples

## Not run:

# Generate some detection and telemetry data, combine them using
# addTelemetry, and perform analyses

# detectors
te <- make.telemetry()
tr <- make.grid(detector = "proximity")

# simulated population and 50% telemetry sample
totalpop <- sim.popn(tr, D = 20, buffer = 100)
tepop <- subset(totalpop, runif(nrow(totalpop)) < 0.5)

# simulated detection histories and telemetry
# the original animalID (renumber = FALSE) are needed for matching
AIC.secr

Compare SECR Models

Description

Terse report on the fit of one or more spatially explicit capture–recapture models. Models with smaller values of AIC (Akaike’s Information Criterion) are preferred. Extraction () and logLik methods are included.

Usage

## S3 method for class 'secr'
AIC(object, ..., sort = TRUE, k = 2, dmax = 10, criterion = c("AICc","AIC"), chat = NULL)
## S3 method for class 'secrlist'
AIC(object, ..., sort = TRUE, k = 2, dmax = 10, criterion = c("AICc","AIC"), chat = NULL)
## S3 method for class 'secr'
logLik(object, ...)
secrlist(...)  
## S3 method for class 'secrlist'

Arguments

- **object**: secr object output from the function `secr.fit`, or a list of such objects with class c("secrlist", "list")
- **...**: other secr objects
- **sort**: logical for whether rows should be sorted by ascending AICc
- **k**: numeric, penalty per parameter to be used; always k = 2 in this method
- **dmax**: numeric, maximum AIC difference for inclusion in confidence set
- **criterion**: character, criterion to use for model comparison and weights
- **chat**: numeric optional variance inflation factor for quasi-AIC
- **x**: secrlist
- **i**: indices

Details

Models to be compared must have been fitted to the same data and use the same likelihood method (full vs conditional). From version 4.1 a warning is issued if `AICcompatible` reveals a problem.

AIC is given by

\[
AIC = -2 \log(L(\hat{\theta})) + 2K
\]

where \( K \) is the number of "beta" parameters estimated.

AIC with small sample adjustment is given by

\[
AIC_c = -2 \log(L(\hat{\theta})) + 2K + \frac{2K(K+1)}{n-K-1}
\]

The sample size \( n \) is the number of individuals observed at least once (i.e. the number of rows in `capthist`).

Model weights are calculated as

\[
w_i = \frac{\exp(-\Delta_i/2)}{\sum \exp(-\Delta_i/2)}
\]

where \( \Delta \) refers to differences in AIC or AICc depending on the argument ‘criterion’. AICc is widely used, but AIC may be better (Fletcher 2018, p. 60).

Models for which delta > dmax are given a weight of zero and are excluded from the summation. Model weights may be used to form model-averaged estimates of real or beta parameters with `modelAverage` (see also Buckland et al. 1997, Burnham and Anderson 2002).

The argument `k` is included for consistency with the generic method `AIC`.

`secrlist` forms a list of fitted models (an object of class ‘secrlist’) from the fitted models in .... Arguments may include secrlists. If secr components are named the model names will be retained (see Examples).
If chat ($\hat{\epsilon}$) is provided then quasi-AIC values are computed (secr >= 4.6.0):

$$QAIC = -2 \log(L(\hat{\theta})) / \hat{\epsilon} + 2K.$$  

**Value**

A data frame with one row per model. By default, rows are sorted by ascending 'criterion' (default AICc).

- **model** character string describing the fitted model
- **detectfn** shape of detection function fitted (halfnormal vs hazard-rate)
- **npar** number of parameters estimated
- **logLik** maximized log likelihood
- **AIC** Akaike’s Information Criterion
- **AICc** AIC with small-sample adjustment of Hurvich & Tsai (1989)

And depending on criterion:

- **dAICc** difference between AICc of this model and the one with smallest AICc
- **AICcwt** AICc model weight

or

- **dAIC** difference between AIC of this model and the one with smallest AIC
- **AICwt** AIC model weight

logLik.secr returns an object of class 'logLik' that has attribute df (degrees of freedom = number of estimated parameters).

If the variance inflation factor ‘chat’ is provided then outputs AIC, AICc etc. are replaced by the corresponding quasi-AIC values labelled QAIC, QAICc etc.

**Note**

It is not be meaningful to compare models by AIC if they relate to different data (see AICcompatible). Specifically:

- an ‘secrlist’ generated and saved to file by mask.check may be supplied as the object argument of AIC.secrlist, but the results are not informative
- models fitted by the conditional likelihood (CL = TRUE) and full likelihood (CL = FALSE) methods cannot be compared
- hybrid mixture models (using hcov argument of secr.fit) should not be compared with other models
- grouped models (using groups argument of secr.fit) should not be compared with other models
- multi-session models should not be compared with single-session models based on the same data.
A likelihood-ratio test (LR.test) is a more direct way to compare two models.

The issue of goodness-of-fit and possible adjustment of AIC for overdispersion has yet to be addressed (cf QAIC in MARK).

From version 2.6.0 the user may select between AIC and AICc for comparing models, whereas previously only AICc was used and AICc weights were reported as ‘AICwt’). There is evidence that AIC may be better for model averaging even when samples are small sizes - Turek and Fletcher (2012).

Examples

## Compare two models fitted previously
## secrdemo.0 is a null model
## secrdemo.b has a learned trap response

AIC(secrdemo.0, secrdemo.b)

## Form secrlist and pass to AIC.secr
temp <- secrlist(null = secrdemo.0, learnedresponse = secrdemo.b)
AIC(temp)

---

<table>
<thead>
<tr>
<th>Model Compatibility</th>
</tr>
</thead>
</table>

**Description**

Determine whether models can be compared by AIC. Incompatibility may be due to difference in the data or the specifications of the groups, hcov or binomN arguments to secr.fit.
AICcompatible

Usage

## S3 method for class 'secr'
AICcompatible(object, ...)
## S3 method for class 'secrlist'
AICcompatible(object, ...)

Arguments

object secr object output from the function secr.fit, or a list of such objects with
class c("secrlist","list")
...
other secr objects

Details

The capthist objects are checked for strict identity with the function identical.
All elements in the output must be TRUE for valid AIC comparison or model averaging using AIC
or AICc.

Value

AIC.secr, modelAverage

Examples

AICcompatible(secrdemo.0, secrdemo.CL)

## Not run:

## A common application of AICcompatible() is to determine
## the compatibility of models fitted with and without the
## fastproximity option.
ovenCHp1 <- reduce(ovenCHp, by = 'all', outputdetector = 'count')
ob1 <- secr.fit(ovenCHp, buffer = 300, details = list(fastproximity = TRUE))
ob2 <- secr.fit(ovenCHp1, buffer = 300, details = list(fastproximity = FALSE))
ob3 <- secr.fit(ovenCHp1, buffer = 300, details = list(fastproximity = FALSE), binomN = 1)
AICcompatible(ob1,ob2)
AICcompatible(ob1,ob3)

## End(Not run)
Description

Method for generic `as.data.frame` function that partially reverses `make.capthist`.

Usage

```r
## S3 method for class 'capthist'
as.data.frame(x, row.names = NULL, optional = FALSE, covariates = FALSE,
fmt = c("trapID", "XY"), ...)
## S3 method for class 'traps'
as.data.frame(x, row.names = NULL, optional = FALSE, usage = FALSE,
covariates = FALSE, ...)
```

Arguments

- `x`: capthist object
- `row.names`: unused argument of generic function
- `optional`: unused argument of generic function
- `covariates`: logical or a character vector of covariates to export
- `fmt`: character string for capture format
- `usage`: logical; if TRUE then usage columns are appended if present
- `...`: other arguments (not used)

Details

By default individual covariates are not exported. When exported they are repeated for each detection of an individual.

Value

A data frame or list of data frames (in the case of a multisession input).

For capthist objects –

The core columns are (Session, ID, Occasion, TrapID) or (Session, ID, Occasion, x, y), depending on the value of `fmt`. Additional columns for covariates and signal strength (detector ‘signal’) are appended to the right.

For traps objects –

The core columns are (x, y). Usage columns are named u1, u2, ..., uS where S is the number of occasions.
Examples

as.data.frame (captdata)
as.data.frame (traps(captdata))

---

**as.mask**

*Coerce traps object to mask*

### Description

This function is used primarily for plotting covariates, for which the `plot.mask` function has greater functionality than `plot.traps`. It also generates pretty maps of grid cells.

### Usage

```r
as.mask(x)
```

### Arguments

- `x` an object of class 'traps'

### Details

A mask derived by coercion with `as.mask` may behave unpredictably e.g., in `secr.fit`.

### Value

If `x` is a single-session traps object –
- an object of class `c("mask", "data.frame")`
If `x` is a multi-session traps object –
- an object of class `c("mask", "list"), for which each component is a single-session mask.

### See Also

`make.mask`, `plot.mask`, `mask`, `traps`

### Examples

```r
plot(as.mask(traps(captdata)), dots = FALSE, meshcol = "black")
plot(traps(captdata), add = TRUE)
```
### as.popn

Coerce ppp object to popn

#### Description

This function converts a spatstat "ppp" object (Baddeley et al. 2015), making it easier to use the simulation capability of spatstat in secr.

#### Usage

```r
as.popn(x)
```

#### Arguments

- `x` an object of class `ppp`

#### Details

Not all attributes are carried over.

#### Value

An object of class `c("popn", "data.frame")` with attribute "boundingbox". The attribute "Lambda" (spatstat class "im") is also carried over if present (used for the intensity surface of LGCP simulations).

#### References

#### See Also

- `sim.popn`, `popn`
autoini

Initial Parameter Values for SECR

Description

Find plausible initial parameter values for secr.fit. A simple SECR model is fitted by a fast ad hoc method.

Usage

autoini(capthist, mask, detectfn = 0, thin = 0.2, tol = 0.001, binomN = 1, adjustg0 = TRUE, adjustsigma = 1.2, ignoreusage = FALSE, ncores = NULL)

Arguments

capthist capthist object
mask mask object compatible with the detector layout in capthist
detectfn integer code or character string for shape of detection function 0 = halfnormal
thin proportion of points to retain in mask
tol numeric absolute tolerance for numerical root finding
binomN integer code for distribution of counts (see secr.fit)
adjustg0 logical for whether to adjust g0 for usage (effort) and binomN
adjustsigma numeric scalar applied to RPSV(capthist, CC = TRUE)
ignoreusage logical for whether to discard usage information from traps(capthist)
ncores integer number of threads to be used for parallel processing

Details

Plausible starting values are needed to avoid numerical problems when fitting SECR models. Actual models to be fitted will usually have more than the three basic parameters output by autoini; other initial values can usually be set to zero for secr.fit. If the algorithm encounters problems obtaining a value for g0, the default value of 0.1 is returned.

Only the halfnormal detection function is currently available in autoini (cf other options in e.g. detectfn and sim.capthist).

autoini implements a modified version of the algorithm proposed by Efford et al. (2004). In outline, the algorithm is

1. Find value of sigma that predicts the 2-D dispersion of individual locations (see RPSV).
2. Find value of g0 that, with sigma, predicts the observed mean number of captures per individual (by algorithm of Efford et al. (2009, Appendix 2))
3. Compute the effective sampling area from g0, sigma, using thinned mask (see esa)
4. Compute D = n/esa(g0, sigma), where n is the number of individuals detected
Here 'find' means solve numerically for zero difference between the observed and predicted values, using `uniroot`.

Halfnormal sigma is estimated with `RPSV(capthist, CC = TRUE)`. The factor `adjustsigma` is applied as a crude correction for truncation of movements at the edge of the detector array.

If `RPSV` cannot be computed the algorithm tries to use observed mean recapture distance \( \bar{d} \). Computation of \( \bar{d} \) fails if there no recaptures, and all returned values are NA.

If the mask has more than 100 points then a proportion \( 1 - \text{thin} \) of points are discarded at random to speed execution.

The argument `tol` is passed to `uniroot`. It may be a vector of two values, the first for \( g0 \) and the second for sigma.

If `traps(capthist)` has a `usage` attribute (defining effort on each occasion at each detector) then the value of \( g0 \) is divided by the mean of the non-zero elements of usage. This adjustment is not precise.

If `adjustg0` is TRUE then an adjustment is made to \( g0 \) depending on the value of `binomN`. For Poisson counts (`binomN = 0`) the adjustment is linear on effort (adjusted \( g0 = g0 / \text{usage} \)). Otherwise, the adjustment is on the hazard scale (adjusted \( g0 = 1 – (1 – g0)^{1 / (\text{usage} \times \text{binomN})} \)). An arithmetic average is taken over all non-zero usage values (i.e. over used detectors and times). If usage is not specified it is taken to be 1.0.

Setting `ncores = NULL` uses the existing value from the environment variable `RCPP_PARALLEL_NUM_THREADS` (see `setNumThreads`).

**Value**

A list of parameter values:

- `D` Density (animals per hectare)
- `g0` Magnitude (intercept) of detection function
- `sigma` Spatial scale of detection function (m)

**Note**

`autoini` always uses the Euclidean distance between detectors and mask points.

You may get this message from `secr.fit`: "'autoini' failed to find g0; setting initial g0 = 0.1". If the fitted model looks OK (reasonable estimates, non-missing SE) there is no reason to worry about the starting values. If you get this message and model fitting fails then supply your own values in the start argument of `secr.fit`.

**BUGS**

*Convert Data To Or From BUGS Format*

### Description

Convert data between ‘capthist’ and BUGS input format.

### Usage

```r
read.DA(DAlist, detector = "polygonX", units = 1, session = 1,
        Y = "Y", xcoord = "U1", ycoord = "U2", xmin = "XL",
        xmax = "XU", ymin = "YL", ymax = "YU", buffer = "delta",
        verify = TRUE)
```

```r
write.DA(capthist, buffer, nzeros = 200, units = 1)
```

### Arguments

- **DAlist**: list containing data in BUGS format
- **detector**: character value for detector type: ‘polygon’ or ‘polygonX’
- **units**: numeric for scaling output coordinates
- **session**: numeric or character label used in output
- **Y**: character, name of binary detection history matrix (animals x occasions)
- **xcoord**: character, name of matrix of x-coordinates for each detection in Y
- **ycoord**: character, name of matrix of y-coordinates for each detection in Y
- **xmin**: character, name of coordinate of state space boundary
- **xmax**: character, name of coordinate of state space boundary
- **ymin**: character, name of coordinate of state space boundary
- **ymax**: character, name of coordinate of state space boundary

---

**BUGS**

*Convert Data To Or From BUGS Format*

### Description

Convert data between ‘capthist’ and BUGS input format.

### Usage

```r
read.DA(DAlist, detector = "polygonX", units = 1, session = 1,
        Y = "Y", xcoord = "U1", ycoord = "U2", xmin = "XL",
        xmax = "XU", ymin = "YL", ymax = "YU", buffer = "delta",
        verify = TRUE)
```

```r
write.DA(capthist, buffer, nzeros = 200, units = 1)
```

### Arguments

- **DAlist**: list containing data in BUGS format
- **detector**: character value for detector type: ‘polygon’ or ‘polygonX’
- **units**: numeric for scaling output coordinates
- **session**: numeric or character label used in output
- **Y**: character, name of binary detection history matrix (animals x occasions)
- **xcoord**: character, name of matrix of x-coordinates for each detection in Y

- **ymin**: character, name of coordinate of state space boundary
- **ymax**: character, name of coordinate of state space boundary
buffer see Details
verify logical if TRUE then the resulting capthist object is checked with verify
capthist capthist object
nzeros level of data augmentation (all-zero detection histories)

Details

Data for OpenBUGS or WinBUGS called from R using the package R2WinBUGS (Sturtz et al. 2005) take the form of an R list.

These functions are limited at present to binary data from a square quadrat such as used by Royle and Young (2008). Marques et al. (2011) provide an R function create.data() for generating simulated datasets of this sort (see sim.capthist for equivalent functionality).

When reading BUGS data –

The character values Y, xcoord, ycoord, xmin etc. are used to locate the data within DAlist, allowing for variation in the input names.

The number of sampling occasions is taken from the number of columns in Y. Each value in Y should be 0 or 1. Coordinates may be missing

A numeric value for buffer is the distance (in the original units) by which the limits Xl, Xu etc. should be shrunk to give the actual plot limits. If buffer is character then a component of DAlist contains the required numeric value.

Coordinates in the output will be multiplied by the scalar units.

Augmentation rows corresponding to ‘all-zero’ detection histories in Y, xcoord, and ycoord are discarded.

When writing BUGS data –

Null (all-zero) detection histories are added to the matrix of detection histories Y, and missing (NA) rows are added to the coordinate matrices xcoord and ycoord.

Coordinates in the output will be divided by the scalar units.

Value

For read.DA, an object of class ‘capthist’.

For write.DA, a list with the components

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XI</td>
<td>left edge of state space</td>
</tr>
<tr>
<td>Xu</td>
<td>right edge of state space</td>
</tr>
<tr>
<td>Yl</td>
<td>bottom edge of state space</td>
</tr>
<tr>
<td>Yu</td>
<td>top edge of state space</td>
</tr>
<tr>
<td>delta</td>
<td>buffer between edge of state space</td>
</tr>
<tr>
<td>nind</td>
<td>number of animals observed</td>
</tr>
<tr>
<td>nzeros</td>
<td>number of added all-zero detection</td>
</tr>
<tr>

`hornedlizardCH, verify.capthist`

Examples

```r
write.DA (hornedlizardCH, buffer = 100, units = 100)

## In this example, the input uses Xl, Xu etc.
## for the limits of the plot itself, so buffer = 0.
## Input is in hundreds of metres.
## First, obtain the list lzdata
olddir <- setwd (system.file("extdata", package="secr"))
source ("lizarddata.R")
setwd(olddir)
str(lzdata)
## Now convert to capthist
tempcapt <- read.DA(lzdata, Y = "H", xcoord = "X",
                   ycoord = "Y", buffer = 0, units = 100)

## Not run:
plot(tempcapt)
secr.fit(tempcapt, trace = FALSE)
## etc.

## End(Not run)
```

capthist  

*Spatial Capture History Object*

description

A capthist object encapsulates all data needed by `secr.fit`, except for the optional habitat mask.
Details

An object of class capthist holds spatial capture histories, detector (trap) locations, individual covariates and other data needed for a spatially explicit capture-recapture analysis with secr.fit.

A capthist is primarily an array of values with `dim(capthist) = c(nc, noccasions, ntraps)` where `nc` is the number of detected individuals. Values maybe binary (`{-1, 0, 1}`) or integer depending on the detector type.

Deaths during the experiment are represented as negative values.

Ancillary data are retained as attributes of a capthist object as follows:

- **traps** — object of class traps (required)
- **session** — session identifier (required)
- **covariates** — dataframe of individual covariates (optional)
- **cutval** — threshold of signal strength for detection (‘signal’ only)
- **signalframe** — signal strength values etc., one row per detection (‘signal’ only)
- **detectedXY** — dataframe of coordinates for location within polygon (‘polygon’-like detectors only)
- **xylist** — coordinates of telemetered animals
- **Tu** — detectors x occasions matrix of sightings of unmarked animals
- **Tm** — detectors x occasions matrix of sightings of marked but unidentified animals
- **Tn** — detectors x occasions matrix of sightings with unknown mark status

`read.capthist` is adequate for most data input. Alternatively, the parts of a capthist object can be assembled with the function `make.capthist`. Use `sim.capthist` for Monte Carlo simulation (simple models only). Methods are provided to display and manipulate capthist objects (print, summary, plot, rbind, subset, reduce) and to extract and replace attributes (covariates, traps, xy).

A multi-session capthist object is a list in which each component is a capthist for a single session. The list maybe derived directly from multi-session input in Density format, or by combining existing capthist objects with `MS.capthist`.

Note

Early versions of secr (before 3.0) used an individual x occasion matrix for data from single-catch and multi-catch traps, instead of a 3-D array. Entries in the matrix corresponded to trap numbers. The function `updateCH` converts the old format.

References

Dissect Spatial Capture History Object

Description

Extract parts of an object of class ‘capthist’.

Usage

animalID(object, names = TRUE, sortorder = c("snk", "ksn"))
occasion(object, sortorder = c("snk", "ksn"))
trap(object, names = TRUE, sortorder = c("snk", "ksn"))
alive(object, sortorder = c("snk", "ksn"))
alongtransect(object, tol = 0.01)
xy(object)
xy(object) <- value
telemetryxy(object, includeNULL = FALSE)
telemetryxy(object) <- value
telemetered(object)

Arguments

object  a ‘capthist’ object
names    if FALSE the values returned are numeric indices rather than names
sortorder character code for sort order (see Details)
tol      tolerance for snapping to transect line (m)
value    replacement value (see Details)
includeNULL logical; if TRUE a NULL component is included for untelemetered animals

Details

These functions extract data on detections, ignoring occasions when an animal was not detected. By default, detections are ordered by occasion, animalID and trap (sortorder = "snk"). The alternative is to order by trap, occasion and animalID (sortorder = "ksn"). (‘n’, ‘s’ and ‘k’ are the indices used internally for animals, occasions and traps respectively).

For historical reasons, "ksn" is used for locations within polygons and similar (xy).
trap returns polygon or transect numbers if traps(object) has detector type ‘polygon’ or ‘transect’.

See Also

traps, secr.fit, read.capthist, make.capthist, sim.capthist, subset.capthist, rbind.capthist, MS.capthist, reduce.capthist, mask
alongtransect returns the distance of each detection from the start of the transect with which it is associated.

Replacement values must precisely match object in number of detections and in their order. xy<- expects a dataframe of x and y coordinates for points of detection within a ‘polygon’ or ‘transect’ detector. telemetryxy<- expects a list of dataframes, one per telemetered animal.

Value

For animalID and trap a vector of numeric or character values, one per detection.
For alive a vector of logical values, one per detection.
For occasion, a vector of numeric values, one per detection.
For xy, a dataframe with one row per detection and columns ‘x’ and ‘y’.
If object has multiple sessions, the result is a list with one component per session.

See Also
capthist, polyID, signalmatrix

Examples

```R
## 'captdata' is a demonstration dataset
animalID(captdata)

temp <- sim.capthist(popn = list(D = 1), make.grid(detector = "count"))
cbind(ID = as.numeric(animalID(temp)), occ = occasion(temp),
      trap = trap(temp))
```

Description

Activity centres may be clumped (overdispersed) relative to a Poisson distribution, the model used in secr.fit (Borchers and Efford 2008). This can cause the sampling variance of density estimates to be understated. One solution currently under investigation is to apply a variance inflation factor, a measure of overdispersion, based on the number of individuals detected at each detector (Bischof et al. 2020).

Functions described here compute the observed (nk) or expected (Enk) number of individuals detected at each detector and use that to compute Fletcher’s ĉ estimate of overdispersion for use as a variance inflation factor.

Enk uses exact formulae for ‘multi’, ‘proximity’ and ‘count’ detector types. Other types may be simulated by setting a positive value for ‘nrepl’, which should be large (e.g., nrepl = 10000).
adjustVarD adjusts the SE and confidence limits of density estimates using Fletcher’s \( \hat{c} \). The implementation is limited to simple detection models (see Warnings).

See Cooch and White (2022) for an introduction to measurement of overdispersion in capture-recapture. The focus here is on overdispersion of activity centres relative to a Poisson distribution, rather than on non-independence in the spatial detection process.

Usage

nk(capthist)

Enk(D, mask, traps, detectfn = 0, detectpar = list(g0 = 0.2, sigma = 25, z = 1), noccasions = NULL, binomN = NULL, userdist = NULL, ncores = NULL, nrepl = NULL)

chat.nk(object, nsim = NULL, ...)

adjustVarD(object, chatmin = 1, alpha = 0.05, chat = NULL)

Arguments

capthist: secr capthist object
D: numeric density, either scalar or vector of length nrow(mask)
mask: single-session habitat mask
traps: traps object
detectfn: integer code for detection function q.v.
detectpar: a named list giving a value for each parameter of detection function
noccasions: number of sampling intervals (occasions)
binomN: integer code for discrete distribution (see secr.fit)
userdist: user-defined distance function or matrix (see userdist)
ncores: integer number of threads
nrepl: integer number of replicates for E(nk) by simulation (optional)
object: fitted secr model or dataframe (see Warnings for restrictions)
nsim: integer number of c-hat values to simulate (optional)
...: other arguments passed to Fletcher.chat (verbose, type)
chatmin: minimum value of Fletcher’s \( \hat{c} \)
alpha: alpha level for confidence intervals
chat: numeric chat (optional)
Details

If traps has a **usage** attribute then noccasions is set accordingly; otherwise it must be provided. The environment variable RCPP_PARALLEL_NUM_THREADS determines the number of parallel threads. It is set to the value of ncores, unless that is NULL (see `setNumThreads`).

A conventional variance inflation factor due to Wedderburn (1974) is \( \hat{c} = \frac{X^2}{(K - p)} \) where \( K \) is the number of detectors, \( p \) is the number of estimated parameters, and

\[
X^2 = \sum_k (n_k - E(n_k))^2 / E(n_k).
\]

Fletcher’s \( \hat{c} \) is an improvement on \( \hat{c} \) that is less affected by small expected counts. It is defined by

\[
\hat{c} = \frac{c}{1 + \bar{s}},
\]

where \( \bar{s} = \sum_k s_k / K \) and \( s_k = (n_k - E(n_k))/E(n_k) \).

chat.nk may be used to simulate \( \hat{c} \) values under the given model (set nsim > 0). The ... argument may include ’ncores = x’ (x>1) to specify parallel processing of simulations - the speed up is large on unix-like machines for which the cluster type of `makeCluster` is "FORK" rather than "PSOCK". If ’ncores’ is not provided then the value returned by `setNumThreads()` is used.

No adjustment is made by adjustVarD when \( \hat{c} \) is less than the minimum. adjustVarD by default computes Fletcher’s ‘chat’ using chat.nk, but a value may be provided.

If chat has been computed separately and provided in the argument of that name, adjustVarD also accepts a single dataframe as the argument ‘object’; the dataframe should have row ‘D’ and columns ‘link’, ‘estimate’, ‘SE.estimate’ as in the output from `predict.secr`.

Value

For nk, a vector of observed counts, one for each detector in traps(capthist).

For Enk, a vector of expected counts, one for each detector in traps.

For chat.nk, usually a list comprising –

- **expected.nk**: expected number at each detector
- **nk**: observed number at each detector
- **stats**: vector of summary statistics: mean(expected.nk), var(expected.nk), mean(nk), var(nk), nu (=df), X2/nu
- **chat**: \( \hat{c} \) (Fletcher or Wedderburn depending on ’type’)

There are two variations –

If ‘verbose = FALSE’ then only the numeric value of \( \hat{c} \) is returned (a vector of 2 values if ‘type = "both"’).

If chat.nk is called with ‘nsim > 0’ then the output is a list comprising –

- **type**: from input
- **nsim**: from input
- **sim.chat**: vector of simulated \( \hat{c} \)
chat  \hat{c} \text{ (Fletcher or Wedderburn depending on 'type')} \\
p \text{ probability of observing } \hat{c} \text{ as large as this (from rank of chat among sim.chat)}

For `adjustVarD`, a dataframe with one row for each session, based on `predict.secr` or `derived.secr`, with extra column 'c-hat'.

**Warning**

These functions are experimental in secr 4.6, and do not work with polygon-like and single-catch detectors. No allowance is made for modelled variation in detection parameters with respect to occasion, detector or animal; this includes mixture models (e.g., g0-h2).

Versions before 4.5.11 did not correctly compute expected counts for multi-catch detectors.

Furthermore, we doubt that the adjustment actually solves the problem of overdispersion (Efford and Fletcher unpubl.).

**Examples**

```r
temptrap <- make.grid()
msk <- make.mask(temptrap)
## expected number of individuals per detector (multi-catch)
Enk (D = 5, msk, temptrap, detectpar = list(g0 = 0.2, sigma = 25),
noccasions = 5)

# useful plotting function for simulated chat (nsim>0)
plotchat <- function(chat, head = '\texttt{Var}', breaks = seq(0.5,2.5,0.05)) {
  hist(chat$sim.chat, xlim = range(breaks), main = head, xlab = 'c-hat',
       breaks = breaks, cex.main = 1, yaxs = 'i')
  abline(v = chat$chat, lwd = 1.5, col = 'blue')
}
```
circular Probability

Description

Functions to answer the question "what radius is expected to include proportion p of points from a circular bivariate distribution corresponding to a given detection function", and the reverse. These functions may be used to relate the scale parameter(s) of a detection function (e.g., σ) to home-range area (specifically, the area within an activity contour for the corresponding simple home-range model) (see Note).

WARNING: the default behaviour of these functions changed in version 2.6.0. Integration is now performed on the cumulative hazard (exposure) scale for all functions unless hazard = FALSE. Results will differ.

Usage

circular.r (p = 0.95, detectfn = 0, sigma = 1, detectpar = NULL, hazard = TRUE, upper = Inf, ...)

circular.p (r = 1, detectfn = 0, sigma = 1, detectpar = NULL, hazard = TRUE, upper = Inf, ...)

Arguments

p vector of probability levels for which radius is required
r vector of radii for which probability level is required
detectfn integer code or character string for shape of detection function 0 = halfnormal, 2 = exponential etc. – see detectfn for other codes
sigma spatial scale parameter of detection function
detectpar named list of detection function parameters
hazard logical; if TRUE the transformation \(-log(1-g(d))\) is applied before integration
upper numeric upper limit of integration
... other arguments passed to integrate

Details

circular.r is the quantile function of the specified circular bivariate distribution (analogous to qnorm, for example). The quantity calculated by circular.r is sometimes called 'circular error probable' (see Note).

For detection functions with two parameters (intercept and scale) it is enough to provide sigma. Otherwise, detectpar should be a named list including parameter values for the requested detection function (g0 may be omitted, and order does not matter).
Detection functions in `secr` are expressed in terms of the decline in probability of detection with distance \( g(d) \), and both `circular.r` and `circular.p` integrate this function by default. Rather than integrating \( g(d) \) itself, it may be more appropriate to integrate \( g(d) \) transformed to a hazard i.e. \( 1 - \log(-g(d)) \). This is selected with `hazard = TRUE`.

Integration may also fail with the message "roundoff error is detected in the extrapolation table". Setting `upper` to a large number less than infinity sometimes corrects this.

**Value**

Vector of values for the required radii or probabilities.

**Note**

The term 'circular error probable' has a military origin. It is commonly used for GPS accuracy with the default probability level set to 0.5 (i.e. half of locations are further than CEP from the true location). A circular bivariate normal distribution is commonly assumed for the circular error probable; this is equivalent to setting `detectfn = "halfnormal"`.

Closed-form expressions are used for the normal and uniform cases; in the circular bivariate normal case, the relationship is \( r = \sigma \sqrt{-2\ln(1-p)} \). Otherwise, the probability is computed numerically by integrating the radial distribution. Numerical integration is not foolproof, so check suspicious or extreme values.

When `circular.r` is used with the default `sigma = 1`, the result may be interpreted as the factor by which `sigma` needs to be inflated to include the desired proportion of activity (e.g., 2.45 `sigma` for 95% of points from a circular bivariate normal distribution fitted on the hazard scale (detectfn = 14) OR 2.24 `sigma` on the probability scale (detectfn = 0)).

## in this example, a more interesting comparison would use
## sigma = 0.58 for the exponential curve.
```

## Description

Clone rows of an object a constant or random number of times

## Usage

```r
## Default S3 method:
clone(object, type, ...)
## S3 method for class 'popn'
clone(object, type, ...)
## S3 method for class 'capthist'
clone(object, type, ...)
```

## Arguments

- `object`: any object
- `type`: character ‘constant’, ‘poisson’, ‘truncatedpoisson’ or ‘nbinom’
- `...`: other arguments for distribution function

## Details

The ... argument specifies the number of times each row should be repeated. For random distributions (Poisson or negative binomial) ... provides the required parameter values: lambda for Poisson, size, prob or size, mu for negative binomial.

One application is to derive a population of cues from a popn object, where each animal in the original popn generates a number of cues from the same point.
Cloning a capthist object replicates whole detection histories. Individual covariates and detection-specific attributes (e.g., signal strength or xy location in polygon) are also replicated. Cloned data from single-catch traps will cause verify() to fail, but a model may still be fitted in secr.fit by overriding the check with verify = FALSE.

Value

Object of same class as object but with varying number of rows. For clone.popn and capthist an attribute 'freq' is set, a vector of length equal to the original number of rows giving the number of repeats (including zeros).

If popn or capthist is a multi-session object the returned value will be a multi-session object of the same length.

See Also

sim.popn

Examples

## population of animals at 1 / hectare generates random
## Poisson number of cues, lambda = 5
mics4 <- make.grid( nx = 2, ny = 2, spacing = 44, detector = "signal")
pop <- sim.popn (D = 1, core = mics4, buffer = 300, nsessions = 6)
pop <- clone (pop, "poisson", 5)
attr(pop[[1]],"freq")
clone(captdata, "poisson", 3)
# To avoid losing any individuals use zero-truncated Poisson
# First find lambda of truncated Poisson with given mean
getlambda <- function (target) {
  fn <- function(x) x / (1-exp(-x)) - target
  uniroot(interval = c(1e-8, target), f = fn)$root
}
clone(captdata, "truncatedpoisson", getlambda(3))

---

closedN Closed population estimates

description

Estimate N, the size of a closed population, by several conventional non-spatial capture-recapture methods.
Usage

closedN(object, estimator = NULL, level = 0.95, maxN = 1e+07,
       dmax = 10 )

Arguments

  object        capthist object
  estimator     character; name of estimator (see Details)
  level         confidence level (1 – alpha)
  maxN          upper bound for population size
  dmax          numeric, the maximum AIC difference for inclusion in confidence set

Details

Data are provided as spatial capture histories, but the spatial information (trapping locations) is ignored.

AIC-based model selection is available for the maximum-likelihood estimators null, zippin, darroch, h2, and betabinomial.

Model weights are calculated as

$$w_i = \frac{\exp(-\Delta_i/2)}{\sum \exp(-\Delta_i/2)}$$

Models for which dAICc > dmax are given a weight of zero and are excluded from the summation, as are non-likelihood models.

Computation of null, zippin and darroch estimates differs slightly from Otis et al. (1978) in that the likelihood is maximized over real values of N between Mt1 and maxN, whereas Otis et al. considered only integer values.

Asymmetric confidence intervals are obtained in the same way for all estimators, using a log transformation of $\hat{N} - Mt_1$ following Burnham et al. (1987), Chao (1987) and Rexstad and Burnham (1991).

The available estimators are

</table>
Value

A dataframe with one row per estimator and columns

| model | model in the sense of Otis et al. 1978 |
| npar | number of parameters estimated |
| loglik | maximized log likelihood |
| AIC | Akaike’s information criterion |
| AICc | AIC with small-sample adjustment of Hurvich & Tsai (1989) |
| dAICc | difference between AICc of this model and the one with smallest AICc |
| Mt1 | number of distinct individuals caught |
| Nhat | estimate of population size |
| seNhat | estimated standard error of Nhat |
| lclNhat | lower 100 x level % confidence limit |
| uclNhat | upper 100 x level % confidence limit |

Warning

If your data are from spatial sampling (e.g. grid trapping) it is recommended that you do not use these methods to estimate population size (see Efford and Fewster 2013). Instead, fit a spatial model and estimate population size with `region.N`.

Note

Prof. Anne Chao generously allowed me to adapt her code for the variance of the ‘chao.th1’ and ‘chao.th2’ estimators.

Chao’s estimators have been subject to various improvements not included here (e.g., Chao et al. 2016).

References

Perform tests to determine whether a population sampled by capture-recapture is closed to gains and losses over the period of sampling.

Usage

closure.test(object, SB = FALSE, min.expected = 2)

Arguments

object capthist object
SB logical, if TRUE then test of Stanley and Burnham 1999 is calculated in addition to that of Otis et al. 1978
min.expected integer for the minimum expected count in any cell of a component 2x2 table

Details

The test of Stanley and Burnham in part uses a sum over 2x2 contingency tables; any table with a cell whose expected count is less than min.expected is dropped from the sum. The default value of 2 is that used by CloseTest (Stanley and Richards 2005, T. Stanley pers. comm.; see also Stanley and Burnham 1999 p. 203).
Value

In the case of a single-session capthist object, either a vector with the statistic (z-value) and p-value for the test of Otis et al. (1978 p. 120) or a list whose components are data frames with the statistics and p-values for various tests and test components as follows –

- **Otis**: Test of Otis et al. 1978
- **Xc**: Overall test of Stanley and Burnham 1999
- **NRvsJS**: Stanley and Burnham 1999
- **NMvsJS**: Stanley and Burnham 1999
- **MtvsNR**: Stanley and Burnham 1999
- **MtvsNM**: Stanley and Burnham 1999
- **compNRvsJS**: Occasion-specific components of NRvsJS
- **compNMvsJS**: Occasion-specific components of NMvsJS

Check the original papers for an explanation of the components of the Stanley and Burnham test.

In the case of a multi-session object, a list with one component (as above) for each session.

Note

No omnibus test exists for closure: the existing tests may indicate nonclosure even when a population is closed if other effects such as trap response are present (see White et al. 1982 pp 96–97).

The test of Stanley and Burnham is sensitive to individual heterogeneity which is inevitable in most spatial sampling, and it should not in general be used for this sort of data.

`closure.test(captdta)`
Detector Clustering

Description

Clusters are uniform groups of detectors. Use these functions to extract or replace cluster information of a `traps` object, or extract cluster information for each detection in a `capthist` object.

Usage

```r
clusterID(object)
clusterID(object) <- value
clustertrap(object)
clustertrap(object) <- value
```

Arguments

- `object`: `traps` or `capthist` object
- `value`: factor (`clusterID`) or integer-valued vector (`clustertrap`)

Details

Easy access to attributes used to define compound designs, those in which a detector array comprises several similar subunits (‘clusters’). ‘clusterID’ identifies the detectors belonging to each cluster, and ‘clustertrap’ is a numeric index used to relate matching detectors in different clusters.

For replacement (‘traps’ only), the number of rows of `value` must match exactly the number of detectors in `object`.

‘clusterID’ and ‘clustertrap’ are assigned automatically by `trap.builder`.

Value

Factor (`clusterID`) or integer-valued vector (`clustertrap`).

`clusterID(object)` may be `NULL`.

See Also

`traps, trap.builder, mash, derivedCluster, cluster.counts, cluster.centres`

Examples

```r
## 25 4-detector clusters
mini <- make.grid(nx = 2, ny = 2)
tempgrid <- trap.builder (cluster = mini , method = "all",
                         frame = expand.grid(x = seq(100, 500, 100), y = seq(100, 500, 100)))
clusterID(tempgrid)
```
coef.secr

## Coefficients of secr Object

### Description

Extract coefficients (estimated beta parameters) from a spatially explicit capture–recapture model.

### Usage

```r
# S3 method for class 'secr'
coef(object, alpha = 0.05, ...)
```

### Arguments

- `object`: secr object output from `secr.fit`
- `alpha`: alpha level
- `...`: other arguments (not used currently)

### Value

A data frame with one row per beta parameter and columns for the coefficient, SE(coefficient), asymptotic lower and upper 100(1–alpha) confidence limits.

### See Also

- `secr.fit`
- `esa.plot`

### Examples

```r
# load & extract coefficients of previously fitted null model
coef(secrdemo.0)
```
collate Array of Parameter Estimates

Description

Estimates from one or more openCR models are formed into an array.

Usage

```r
## S3 method for class 'secr'
collate(object, ..., realnames = NULL, betanames = NULL, newdata = NULL,
       alpha = 0.05, perm = 1:4, fields = 1:4)
## S3 method for class 'ipsecr'
collate(object, ..., realnames = NULL, betanames = NULL, newdata = NULL,
       alpha = 0.05, perm = 1:4, fields = 1:4)
## S3 method for class 'secrlist'
collate(object, ..., realnames = NULL, betanames = NULL, newdata = NULL,
       alpha = 0.05, perm = 1:4, fields = 1:4)
```

Arguments

- `object` secr or secrlist object
- `...` other secr objects
- `realnames` character vector of real parameter names
- `betanames` character vector of beta parameter names
- `newdata` optional dataframe of values at which to evaluate models
- `alpha` alpha level for confidence intervals
- `perm` permutation of dimensions in output from collate
- `fields` vector to restrict summary fields in output

Details

collate extracts parameter estimates from a set of fitted secr model objects.

`fields` may be used to select a subset of summary fields ("estimate","SE.estimate","lcl","ucl") by name or number.
Value
A 4-dimensional array of model-specific parameter estimates. By default, the dimensions correspond respectively to

- rows in newdata (usually sessions),
- models,
- statistic fields (estimate, SE.estimate, lcl, ucl), and
- parameters ("phi", "sigma" etc.).

It often helps to reorder the dimensions with the perm argument.

collate(secrdemo.0, secrdemo.b, perm = c(4,2,3,1))[,,1,]

confint.secr

Profile Likelihood Confidence Intervals

Description
Compute profile likelihood confidence intervals for ‘beta’ or ‘real’ parameters of a spatially explicit capture-recapture model,

Usage

## S3 method for class 'secr'
confint(object, parm, level = 0.95, newdata = NULL,
tracelevel = 1, tol = 0.0001, bounds = NULL, ncores = NULL, ...)

Arguments

object secr model object
parm numeric or character vector of parameters
level confidence level (1 – alpha)
newdata optional dataframe of values at which to evaluate model
tracelevel integer for level of detail in reporting (0,1,2)
tol absolute tolerance (passed to uniroot)
bounds numeric vector of outer starting values – optional
ncores number of threads used for parallel processing
... other arguments (not used)
Details

If `parm` is numeric its elements are interpreted as the indices of ‘beta’ parameters; character values are interpreted as ‘real’ parameters. Different methods are used for beta parameters and real parameters. Limits for the $j$-th beta parameter are found by a numerical search for the value satisfying $-2(l_j(\beta_j) - l) = q$, where $l$ is the maximized log likelihood, $l_j(\beta_j)$ is the maximized profile log likelihood with $\beta_j$ fixed, and $q$ is the $100(1 - \alpha)$ quantile of the $\chi^2$ distribution with one degree of freedom. Limits for real parameters use the method of Lagrange multipliers (Fletcher and Faddy 2007), except that limits for constant real parameters are backtransformed from the limits for the relevant beta parameter.

If bounds is provided it should be a 2-vector or matrix of 2 columns and length(parm) rows.

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).

Value

A matrix with one row for each parameter in `parm`, and columns giving the lower (lcl) and upper (ucl) $100\alpha$ level

Note

Calculation may take a long time, so probably you will do it only after selecting a final model.

The R function `uniroot` is used to search for the roots of $-2(l_j(\beta_j) - l) = q$ within a suitable interval. The interval is anchored at one end by the MLE, and at the other end by the MLE inflated by a small multiple of the asymptotic standard error (1, 2, 4 or 8 SE are tried in turn, using the smallest for which the interval includes a valid solution).

A more efficient algorithm was proposed by Venzon and Moolgavkar (1988); it has yet to be implemented in secr, but see plkhci in the package Bhat for another R implementation.

References

Examples

```r
## Not run:
## Limits for the constant real parameter "D"
confint(secrdemo.0, "D")
## End(Not run)
```
Contour Detection Probability

Description

Display contours of the net probability of detection p(X), or the area within a specified distance of detectors. `buffer.contour` adds a conventional ‘boundary strip’ to a detector (trap) array, where buffer equals the strip width.

Usage

```r
dot.contour(traps, border = NULL, nx = 64, detectfn = 0,
            detectpar = list(g0 = 0.2, sigma = 25, z = 1), noccasions = NULL,
            binomN = NULL, levels = seq(0.1, 0.9, 0.1), poly =
            NULL, poly.habitat = TRUE, plt = TRUE, add = FALSE, fill = NULL, ...)
buffer.contour(traps, buffer, nx = 64, convex = FALSE, ntheta = 100,
              plt = TRUE, add = FALSE, poly = NULL, poly.habitat = TRUE,
              fill = NULL, ...)
```

Arguments

- **traps**: traps object (or mask for `buffer.contour`)
- **border**: width of blank margin around the outermost detectors
- **nx**: dimension of interpolation grid in x-direction
- **detectfn**: integer code or character string for shape of detection function 0 = halfnormal etc. – see `detectfn`
- **detectpar**: list of values for named parameters of detection function
- **noccasions**: number of sampling occasions
- **binomN**: integer code for discrete distribution (see `secr.fit`)
- **levels**: vector of levels for p(X)
- **poly**: matrix of two columns, the x and y coordinates of a bounding polygon (optional)
- **poly.habitat**: logical as in `make.mask`
- **plt**: logical to plot contours
- **add**: logical to add contour(s) to an existing plot
- **fill**: vector of colours to fill contours (optional)
- **...**: other arguments to pass to `contour`
- **buffer**: vector of buffer widths
- **convex**: logical, if TRUE the plotted contour(s) will be convex
- **ntheta**: integer value for smoothness of convex contours
Details

`pdot.contour` constructs a rectangular mask and applies `pdot` to compute the p.(X) at each mask point.

If `convex = FALSE`, `buffer.contour` constructs a mask and contours the points on the basis of distance to the nearest detector at the levels given in `buffer`.

If `convex = TRUE`, `buffer.contour` constructs a set of potential vertices by adding points on a circle of radius = `buffer` to each detector location; the desired contour is the convex hull of these points (this algorithm derives from Efford, 2012).

If `traps` has a `usage` attribute then `noccasions` is set accordingly; otherwise it must be provided.

If `traps` is for multiple sessions then detectpar should be a list of the same length, one component per session, and noccasions may be a numeric vector of the same length.

Increase `nx` for smoother lines, at the expense of speed.

Value

Coordinates of the plotted contours are returned as a list with one component per polygon. The list is returned invisibly if `plt = TRUE`.

For multi-session input (`traps`) the value is a list of such lists, one per session.

Note

The precision (smoothness) of the fitted line in `buffer.contour` is controlled by `ntheta` rather than `nx` when `convex = TRUE`.

To suppress contour labels, include the argument `drawlabels = FALSE` (this will be passed via `...` to `contour`). Other useful arguments of `contour` are `col` (colour of contour lines) and `lwd` (line width).

You may wish to consider function `st_buffer` in package `sf` as an alternative to `buffer.contour`.

`buffer.contour` failed with multi-session `traps` before `secr 2.8.0`.

## End(Not run)

covariates            Covariates Attribute

<table>
<thead>
<tr>
<th>Description</th>
<th>Extract or replace covariates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage</td>
<td>covariates(object, ...)</td>
</tr>
<tr>
<td></td>
<td>covariates(object) &lt;- value</td>
</tr>
</tbody>
</table>
**Arguments**

- **object**: an object of class `traps`, `popn`, `capthist`, or `mask`
- **value**: a dataframe of covariates
- **...**: other arguments (not used)

**Details**

For replacement, the number of rows of `value` must match exactly the number of rows in `object`.

**Value**

covariates(`object`) returns the dataframe of covariates associated with `object`. `covariates(`object`)` may be NULL.

Individual covariates are stored in the 'covariates' attribute of a `capthist` object.

Covariates used for modelling density are stored in the 'covariates' attribute of a `mask` object.

Detector covariates may vary between sampling occasions. In this case, columns in the detector covariates data.frame are associated with particular times; the matching is controlled by the `timevaryingcov` attribute.

**See Also**

- `timevaryingcov`

**Examples**

```r
## detector covariates
temptrap <- make.grid(nx = 6, ny = 8)
covariates(temptrap) <- data.frame(halfnhalf = factor(rep(c("left","right"),c(24,24))) )
summary(covariates(temptrap))
```

---

### CV

**Coefficient of Variation**

The coefficient of variation of effective sampling area predicts the bias in estimated density (Efford and Mowat 2014). These functions assist its calculation from fitted finite mixture models.

**Usage**

```r
CV(x, p, na.rm = FALSE)
CVa0(object, ...)
CVa(object, sessnum = 1, ...)
```
Arguments

- **x**: vector of numeric values
- **p**: vector of class probabilities
- **na.rm**: logical; if TRUE missing values are dropped from x
- **object**: fitted secr finite mixture model
- **sessnum**: integer sequence number of session to analyse
- **...**: other arguments passed to predict.secr (e.g., newdata)

Details

`CV` computes the coefficient of variation of `x`. If `p` is provided then the distribution is assumed to be discrete, with support `x` and class membership probabilities `p` (scaled automatically to sum to 1.0).

`CVa` computes `CV(a)` where `a` is the effective sampling area of Borchers and Efford (2008).

`CVa0` computes `CV(a0)` where `a0` is the single-detector sampling area defined as

\[
a_0 = 2\pi \lambda_0 \sigma^2
\]

(Efford and Mowat 2014); `a0` is a convenient surrogate for `a`, the effective sampling area. `CV(a0)` uses either the fitted MLE of `a0` (if the `a0` parameterization has been used), or `a0` computed from the estimates of `lambda0` and `sigma`.

`CVa` and `CVa0` do not work for models with individual covariates.

Value

Numeric

Note

Do not confuse the function `CVa` with the estimated relative standard error of the estimate of `a` from `derived`, also labelled `CVa` in the output. The relative standard error `RSE` is often labelled `CV` in the literature on capture-recapture, but this can cause unnecessary confusion. See also `RSE`.

```r
msk <- make.mask((traps(morning)), nx = 32)
morning.h2 <- secr.fit(morning, buffer = 20, model = list(h2~g0), mask = msk,
                      trace = FALSE)
CVa0(morning.h2)
```

## End(Not run)

### D.designdata

**Construct Density Design Data**

**Description**

Internal function used by `secr.fit`, `confint.secr`, and `score.test`.

**Usage**

```r
D.designdata (mask, Dmodel, grouplevels, sessionlevels, sessioncov =
              NULL, meanSD = NULL)
```

**Arguments**

- `mask`: `mask` object.
- `Dmodel`: formula for density model
- `grouplevels`: vector of group names
- `sessionlevels`: vector of character values for session names
- `sessioncov`: optional dataframe of values of session-specific covariate(s).
- `meanSD`: optional external values for scaling x- and y- coordinates

**Details**

This is an internal `secr` function that you are unlikely ever to use. Unlike `secr.design.MS`, this function does not call `model.matrix`.

**Value**

Dataframe with one row for each combination of mask point, group and session. Conceptually, we use a 3-D rectangular array with enough rows to accommodate the largest mask, so some rows in the output may merely hold space to enable easy indexing. The dataframe has an attribute ‘dimD’ that gives the relevant dimensions: `attr(dframe, "dimD") = c(nmask, ngrp, R)`, where `nmask` is the number of mask points, `ngrp` is the number of groups, and `R` is the number of sessions. Columns correspond to predictor variables in Dmodel.

The number of valid rows (points in each session-specific mask) is stored in the attribute ‘valid-MaskRows’.

For a single-session mask, `meanSD` is a 2 x 2 matrix of mean and SD (rows) for x- and y-coordinates. For a multi-session mask, a list of such objects. Ordinarily these values are from the `meanSD` attribute of the mask, but they must be specified when applying a new mask to an existing model.
Deermouse Live-trapping Datasets

Description

Data of V. H. Reid from live trapping of deermices (*Peromyscus maniculatus*) at two sites in Colorado, USA.

Usage

deermouse.ESG
deermouse.WSG

Details

Two datasets of V. H. Reid were described by Otis et al. (1978) and distributed with their CAPTURE software (now available from https://www.mbr-pwrc.usgs.gov/software.html). They have been used in several other papers on closed population methods (e.g., Huggins 1991, Stanley and Richards 2005). This description is based on pages 32 and 87–93 of Otis et al. (1978).

Both datasets are from studies in Rio Blanco County, Colorado, in the summer of 1975. Trapping was for 6 consecutive nights. Traps were arranged in a 9 x 11 grid and spaced 50 feet (15.2 m) apart.

The first dataset was described by Otis et al. (1978: 32) as from ‘a drainage bottom of sagebrush, gambel oak, and serviceberry with pinyon pine and juniper on the uplands’. By matching with the ‘examples’ file of CAPTURE this was from East Stuart Gulch (ESG).

The second dataset (Otis et al. 1978: 87) was from Wet Swizer Creek or Gulch (WSG) in August 1975. No specific vegetation description is given for this site, but it is stated that Sherman traps were used and trapping was done twice daily.

Two minor inconsistencies should be noted. Although Otis et al. (1978) said they used data from morning trap clearances, the capture histories in ‘examples’ from CAPTURE include a ‘pm’ tag on each record. We assume the error was in the text description, as their numerical results can be reproduced from the data file. Huggins (1991) reproduced the East Stuart Gulch dataset (omitting spatial data that were not relevant to his method), but omitted two capture histories.

The data are provided as two single-session capthist objects ‘deermouse.ESG’ and ‘deermouse.WSG’. Each has a dataframe of individual covariates, but the fields differ between the two study areas. The individual covariates of deermouse.ESG are sex (factor levels ‘f’, ‘m’), age class (factor levels ‘y’, ‘sa’, ‘a’) and body weight in grams. The individual covariates of deermouse.WSG are sex (factor levels ‘f’, ‘m’) and age class (factor levels ‘j’, ‘y’, ‘sa’, ‘a’) (no data on body weight). The aging criteria used by Reid are not recorded.
The datasets were originally in the CAPTURE ‘xy complete’ format which for each detection gives the ‘column’ and ‘row’ numbers of the trap (e.g. ‘9 5’ for a capture in the trap at position (x=9, y=5) on the grid). Trap identifiers have been recoded as strings with no spaces by inserting zeros (e.g. ‘905’ in this example).

Sherman traps are designed to capture one animal at a time, but the data include double captures (1 at ESG and 8 at WSG – see Examples). The true detector type therefore falls between ‘single’ and ‘multi’. Detector type is set to ‘multi’ in the distributed data objects.

Description

Mask points may be removed by one of three methods: clicking on points, clicking on vertices to define a polygon from which points will be removed, or specifying a polygon to which the mask will be clipped.

Usage

deletemaskPoints(mask, onebyone = TRUE, add = FALSE, poly = NULL, poly.habitat = FALSE, ...)

Arguments

- **mask**: secr mask object
- **onebyone**: logical; see Details
- **add**: logical; if true then the initial mask plot will be added to an existing plot
- **poly**: polygon defining habitat or non-habitat as described in `make.mask`
- **poly.habitat**: logical; if TRUE polygon represents habitat
- **...**: other arguments to plot.mask

Details

The default method (onebyone = TRUE, poly = NULL) is to click on each point to be removed. The nearest mask point will be selected.

Setting onebyone = FALSE allows the user to click on the vertices of a polygon within which all points are to be removed (the default) or retained (poly.habitat = TRUE). Vertices need not coincide with mask points.

Defining poly here is equivalent to calling `make.mask` with poly defined. poly one of the several types described in `boundarytoSF`. Whether poly represents habitat or non-habitat is toggled with poly.habitat – the default here differs from `make.mask`.

Value

A mask object, usually with fewer points than the input mask.

See Also

- `make.mask`, `subset.mask`
Examples

```r
if (interactive()) {
    mask0 <- make.mask (traps(captdata))
    ## Method 1 - click on each point to remove
    mask1 <- deleteMaskPoints (mask0)
    ## Method 2 - click on vertices of removal polygon
    mask2 <- deleteMaskPoints (mask0, onebyone = FALSE)
    ## Method 3 - predefined removal polygon
    plot(captdata)
    poly1 <- locator(5)
    mask3 <- deleteMaskPoints (mask0, poly = poly1)
}
```

---

**derived**

**Derived Parameters of Fitted SECR Model**

**Description**

Compute derived parameters of spatially explicit capture-recapture model. Density is a derived parameter when a model is fitted by maximizing the conditional likelihood. So also is the effective sampling area (in the sense of Borchers and Efford 2008).

**Usage**

```r
derived(object, ...)
```

```r
## S3 method for class 'secr'
derived(object, sessnum = NULL, groups = NULL, alpha = 0.05,
    se.esa = FALSE, se.D = TRUE, loginterval = TRUE, distribution = NULL,
    ncores = NULL, bycluster = FALSE, ...)
```

```r
## S3 method for class 'secrlist'
derived(object, sessnum = NULL, groups = NULL, alpha = 0.05,
    se.esa = FALSE, se.D = TRUE, loginterval = TRUE, distribution = NULL,
    ncores = NULL, bycluster = FALSE, ...)
```

```r
esa(object, sessnum = 1, beta = NULL, real = NULL, nooccasions = NULL,
    ncores = NULL)
```

**Arguments**

- **object** secr object output from secr.fit, or an object of class c("secrlist", "list")
- **sessnum** index of session in object$capthist for which output required
groups vector of covariate names to define group(s) (see Details)
alpha alpha level for confidence intervals
se.esa logical for whether to calculate SE(mean(esa))
se.D logical for whether to calculate SE(D-hat)
loginterval logical for whether to base interval on log(D)
distribution character string for distribution of the number of individuals detected
ncores integer number of threads used for parallel processing
bycluster logical; if TRUE results are reported separately for each cluster of detectors
beta vector of fitted parameters on transformed (link) scale
real vector of ‘real’ parameters
noccasions integer number of sampling occasions (see Details)
... other arguments (not used)

Details

The derived estimate of density is a Horvitz-Thompson-like estimate:

\[ \hat{D} = \sum_{i=1}^{n} a_i(\hat{\theta})^{-1} \]

where \( a_i(\hat{\theta}) \) is the estimate of effective sampling area for animal \( i \) with detection parameter vector \( \theta \).

A non-null value of the argument distribution overrides the value in object$details. The sampling variance of \( \hat{D} \) from secr.fit by default is spatially unconditional (distribution = "Poisson"). For sampling variance conditional on the population of the habitat mask (and therefore dependent on the mask area), specify distribution = "binomial". The equation for the conditional variance includes a factor \( (1 - a/A) \) that disappears in the unconditional (Poisson) variance (Borchers and Efford 2007). Thus the conditional variance is always less than the unconditional variance. The unconditional variance may in turn be an overestimate or (more likely) an underestimate if the true spatial variance is non-Poisson.

Derived parameters may be estimated for population subclasses (groups) defined by the user with the groups argument. Each named factor in groups should appear in the covariates dataframe of object$capthist (or each of its components, in the case of a multi-session dataset).

esa is used by derived to compute individual-specific effective sampling areas:

\[ a_i(\hat{\theta}) = \int_A p.(X; z_i, \hat{\theta}) \, dX \]

where \( p.(X) \) is the probability an individual at \( X \) is detected at least once and the \( z_i \) are optional individual covariates. Integration is over the area \( A \) of the habitat mask.

The argument noccasions may be used to vary the number of sampling occasions; it works only when detection parameters are constant across individuals and across time.

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).
The effective sampling area ‘esa’ \( (a(\hat{\theta})) \) reported by derived is equal to the harmonic mean of the 
\( a_i(\hat{\theta}) \) (arithmetic mean prior to version 1.5). The sampling variance of \( a(\hat{\theta}) \) is estimated by

\[
\hat{\text{var}}(a(\hat{\theta})) = \hat{G}_\theta^T \hat{V}_\theta \hat{G}_\theta,
\]

where \( \hat{V} \) is the asymptotic estimate of the variance-covariance matrix of the beta detection parameters \( (\theta) \) and \( \hat{G} \) is a numerical estimate of the gradient of \( a(\hat{\theta}) \) with respect to \( \theta \), evaluated at \( \hat{\theta} \).

A 100(1–alpha)% asymptotic confidence interval is reported for density. By default, this is asymmetric about the estimate because the variance is computed by backtransforming from the log scale. You may also choose a symmetric interval (variance obtained on natural scale).

The vector of detection parameters for esa may be specified via beta or real, with the former taking precedence. If neither is provided then the fitted values in object$fit$par are used. Specifying real parameter values bypasses the various linear predictors. Strictly, the ‘real’ parameters are for a naive capture (animal not detected previously).

The computation of sampling variances is relatively slow and may be suppressed with se.esa and se.D as desired.

For computing derived across multiple models in parallel see par.derived.

**Value**

Dataframe with one row for each derived parameter (‘esa’, ‘D’) and columns as below

- **estimate**: estimate of derived parameter
- **SE.estimate**: standard error of the estimate
- **lcl**: lower 100(1–alpha)% confidence limit
- **ucl**: upper 100(1–alpha)% confidence limit
- **CVn**: relative SE of number observed (Poisson or binomial assumption)
- **CVa**: relative SE of effective sampling area
- **CVD**: relative SE of density estimate

For a multi-session or multi-group analysis the value is a list with one component for each session and group.

The result will also be a list if object is an ‘secrlist’.

**Warning**

derived() may be applied to detection models fitted by maximizing the full likelihood \( (\text{CL} = \text{FALSE}) \). However, models using \( g \) (groups) will not be handled correctly.

**Note**

Before version 2.1, the output table had columns for ‘varcomp1’ (the variance in \( \hat{D} \) due to variation in \( n \), i.e., Huggins’ \( s^2 \)), and ‘varcomp2’ (the variance in \( \hat{D} \) due to uncertainty in estimates of detection parameters).

These quantities are related to CVn and CVa as follows:

\[
CVn = \sqrt{\text{varcomp1}} / \hat{D}
\]
CVa = \sqrt{\text{varcomp2}}/\hat{D}

Details

The function secr.fit allows many options. Some of these are used infrequently and have been bundled as a single argument details to simplify the documentation. They are described here.

Detail components

details$autoini specifies the session number from which to compute starting values (multi-session data only; default 1). From 4.0.0, the character value ‘all’ first forms a single-session capthist using join(); this may be slow or not work at all (especially with telemetry data).

details$centred = TRUE causes coordinates of both traps and mask to be centred on the centroid of the traps, computed separately for each session in the case of multi-session data. This may be
necessary to overcome numerical problems when x- or y-coordinates are large numbers. The default is not to centre coordinates.

details$chat optionally specifies the overdispersion of unmarked sightings Tu and unidentified marked sightings Tm. It is used only for mark-resight models, and is usually computed within secr.fit (details$nsim > 0), but may be provided by the user. For a single session ‘chat’ is a vector of length 2; for multiple sessions it is a 2-column matrix.

details$chatonly = TRUE used with details$nsim > 0 causes the overdispersion statistics for sighting counts Tu and Tm to be estimated and returned as a vector or 2-column matrix (multi-session models), with no further model fitting.

details$contrasts may be used to specify the coding of factor predictors. The value should be suitable for the ‘contrasts.arg’ argument of model.matrix. See ‘Trend across sessions’ in secr-multisession.pdf for an example.

details$convexpolygon may be set to FALSE for searches of non-convex polygons. This is slower than the default which requires polygons to be convex east-west (secr-polygondetectors.pdf).

details$debug is an integer code used to control the printing of intermediate values (1,2) and to switch on the R code browser (3). In ordinary use it should not be changed from the default (0).

details$Dfn is a function for reparameterizing density models; this is set internally when Dlambda = TRUE. Exotic variations may be specified directly by the user when Dlambda = FALSE. The defaults (Dfn = NULL, Dlambda = FALSE) leave the original density model unchanged. Note there is no connection to userDfn (except that the two are incompatible).

Dlambda if TRUE causes reparameterization of density as the session-on-session finite rate of increase lambda. Details at (secr-trend.pdf).

details$distribution specifies the distribution of the number of individuals detected n; this may be conditional on the number in the masked area ("binomial") or unconditional ("poisson"). distribution affects the sampling variance of the estimated density. The default is "poisson". The component ‘distribution’ may also take a numeric value larger than nrow(capthist), rather than "binomial" or "poisson". The likelihood then treats n as a binomial draw from a superpopulation of this size, with consequences for the variance of density estimates. This can help to reconcile MLE with Bayesian estimates using data augmentation.

details$fastproximity controls special handling of data from binary proximity and count detectors. If TRUE and other conditions are met (no temporal variation or groups) then a multi-occasion capthist is automatically reduced to a count for a single occasion and further compressed by storing only non-zero counts, which can greatly speed up computation of the likelihood (default TRUE).

details$fixedbeta may be used to fix values of beta parameters. It should be a numeric vector of length equal to the total number of beta parameters (coefficients) in the model. Parameters to be estimated are indicated by NA. Other elements should be valid values on the link scale and will be substituted during likelihood maximisation. Check the order of beta parameters in a previously fitted model.

details$grain sets the grain argument for multithreading in RcppParallel parallelFor (default 1). details$grain = 0 suppresses multithreading (equivalent to ncores = 1).

details$hessian is a character string controlling the computation of the Hessian matrix from which variances and covariances are obtained. Options are "none" (no variances), "auto" (the default) or "fdhess" (use the function fdHess in nlme). If "auto" then the Hessian from the optimisation function is used. See also method = "none" below.
details$ignoreusage = TRUE causes the function to ignore usage (varying effort) information in the traps component. The default (details$ignoreusage = FALSE) is to include usage in the model.

details$intwidth2 controls the half-width of the interval searched by optimise() for the maximum likelihood when there is a single parameter. Default 0.8 sets the search interval to (0.2s, 1.8s) where s is the 'start' value.

details$knownmarks = FALSE causes secr.fit to fit a zero-truncated sightings-only model that implicitly estimates the number of marked individuals, rather than inferring it from the number of rows in the capthist object.

details$LLonly = TRUE causes the function to return a single evaluation of the log likelihood at the 'start' values.

details$maxdistance sets a limit to the centroid-to-mask distances considered. The centroid is the geometric mean of detection locations for each individual. If no limit is specified then summation is over all mask points. Specifying maxdistance can speed up computation; it is up to the user to select a limit that is large enough not to affect the likelihood (5σ?).

details$miscparm (default NULL) is an optional numeric vector of starting values for additional parameters used in a user-supplied distance function (see 'userdist' below). If the vector has a names attribute then the names will be used for the corresponding coefficients ('beta' parameters) which will otherwise be named 'miscparm1', 'miscparm2' etc. These parameters are constant across each model and do not appear in the model formula, but are estimated along with other coefficients when the likelihood is maximised. Any transformation (link function) etc. is handled by the user in the userdist function. The coefficients appear in the output from coef.secr and vcov.secr, but not predict.secr.

details$newdetector specifies a detector type to use for this fit, replacing the previous detector(traps(capthist)). The value may be a vector (one value per occasion) or for multi-session data, a list of vectors. A scalar value (e.g. "proximity") is otherwise used for all occasions and sessions. The true detector type is usually known and will be specified in the 'traps' attribute; newdetector is useful in simulation studies that examine the effect of misspecification. The capthist component of the output from secr.fit has the new type.

details$nsim specifies the number of replicate simulations to perform to estimate the overdispersion statistics for the sighting counts Tu and Tm. See also details$chat and details$chatonly.

details$param chooses between various parameterisations of the SECR model. The default details$param = 0 is the formulation in Borchers and Efford (2008) and later papers.

details$param = 1 was once used to select the Gardner & Royle parameterisation of the detection model \(p0, \sigma\); Gardner et al. 2009) when the detector type is 'multi'. This parameterisation was discontinued in 2.10.0.

details$param = 2 selects parameterisation in terms of \(\text{esa}(g0, \sigma), \sigma\) (Efford and Mowat 2014).

details$param = 3 selects parameterisation in terms of \(a0(\lambda0, \sigma), \sigma\) (Efford and Mowat 2014). This parameterization is used automatically if a0 appears in the model (e.g., a0 ~ 1).

details$param = 4 selects parameterisation of sigma in terms of the coefficient sigmak and constant c (sigma = sigmak / D^0.5 + c) (Efford et al. 2016). If c is not included explicitly in the model (e.g., c ~ 1) then it is set to zero. This parameterization is used automatically if sigmak appears in the model (e.g., sigmak ~ 1)

details$param = 5 combines parameterisations (3) and (4) (first compute sigma from D, then compute lambda0 from sigma).
details$savecall determines whether the full call to secr.fit is saved in the output object. The default is TRUE except when called by par.secr.fit as names in the call are then evaluated, causing the output to become unwieldy.

details$splitmarked determines whether the home range centre of marked animals is allowed to move between the marking and sighting phases of a spatial capture–mark–resight study. The default is to assume a common home-range centre (splitmarked = FALSE).

details$telemetrytype determines how telemetry data in the attribute ‘xyst’ are treated. ‘none’ causes the xyst data to be ignored. ‘dependent’ uses information on the sampling distribution of each home-range centre in the SECR likelihood. ‘concurrent’ does that and more: it splits capthist according to telemetry status and appends all-zero histories to the telemetry part for any animals present in xyst. The default is ‘concurrent’.

details$usecov selects the mask covariate to be used for normalization. NULL limits denominator to distinguishing habitat from non-habitat.

details$userDfn is a user-provided function for modelling a density surface. See secr-densitysurfaces.pdf

details$userdist is either a function to compute non-Euclidean distances between detectors and mask points, or a pre-computed matrix of such distances. The first two arguments of the function should be 2-column matrices of x-y coordinates (respectively k detectors and m mask points). The third argument is a habitat mask that defines a non-Euclidean habitat geometry (a linear geometry is described in documentation for the package ‘secrlinear’). The matrix returned by the function must have exactly k rows and m columns. When called with no arguments the function should return a character vector of names for the required covariates of ‘mask’, possibly including the dynamically computed density ‘D’ and a parameter ‘noneuc’ that will be fitted. A slightly expanded account is at userdist, and full documentation is in the separate document secr-noneuclidean.pdf.

**Do not use ‘userdist’ for polygon or transect detectors**

**detectfn**  
*Detection Functions*

**Description**

A detection function relates the probability of detection \( g \) or the expected number of detections \( \lambda \) for an animal to the distance of a detector from a point usually thought of as its home-range centre. In secr only simple 2- or 3-parameter functions are used. Each type of function is identified by its number or by a 2–3 letter code (version \( \geq 2.6.0 \); see below). In most cases the name may also be used (as a quoted string).

Choice of detection function is usually not critical, and the default ‘HN’ is usually adequate.

Functions (14)–(20) are parameterised in terms of the expected number of detections \( \lambda \), or cumulative hazard, rather than probability. ‘Exposure’ (e.g., Royle and Gardner 2011) is another term for cumulative hazard. This parameterisation is natural for the ‘count’ detector type or if the function is to be interpreted as a distribution of activity (home range). When one of the functions (14)–(19) is used to describe detection probability (i.e., for the binary detectors ‘single’, ‘multi’, ‘proximity’, ‘polygonX’ or ‘transectX’), the expected number of detections is internally transformed to a binomial probability using \( g(d) = 1 - \exp(-\lambda(d)) \).

The hazard halfnormal (14) is similar to the halfnormal exposure function used by Royle and Gardner (2011) except they omit the factor of 2 on \( \sigma^2 \), which leads to estimates of \( \sigma \) that are larger by a factor of \( \sqrt{2} \). The hazard exponential (16) is identical to their exponential function.

15 HHR hazard rate lambda0, sigma, z \lambda(d) = \lambda_0(1 - \exp\left( -\left( d/\sigma \right)^2 \right)); g(d) = 1 - \exp(-\lambda(d))
16 HEX hazard exponential lambda0, sigma \lambda(d) = \lambda_0 \exp\left( -\left( d/\sigma \right)^2 \right); g(d) = 1 - \exp(-\lambda(d))
17 HAN hazard annular normal lambda0, sigma, w \lambda(d) = \lambda_0 \exp\left( -\left( d-w \right)^2/2\sigma^2 \right); g(d) = 1 - \exp(-\lambda(d))
18 HCG hazard cumulative gamma lambda0, sigma, z \lambda(d) = \lambda_0\{1 - G(d; k, \theta) \}; g(d) = 1 - \exp(-\lambda(d))
19 HVP hazard variable power lambda0, sigma, z \lambda(d) = \lambda_0 \exp\left( -\left( d/\sigma \right)^2 \right); g(d) = 1 - \exp(-\lambda(d))
20 HPX hazard pixelar lambda0, sigma g(d') = 1 - \exp(-\lambda(d')); d' <= \sigma; g(d') = 0, otherwise

Functions (1) and (15), the "hazard-rate" detection functions described by Hayes and Buckland (1983), are not recommended for SECR because of their long tail, and care is also needed with (2) and (16).

Function (3), the compound halfnormal, follows Efford and Dawson (2009).

Function (4) uniform is defined only for simulation as it poses problems for likelihood maximisation by gradient methods. Uniform probability implies uniform hazard, so there is no separate function 'HUN'.

For function (7), 'F' is the standard normal distribution function and \( \mu \) and \( s \) are the mean and standard deviation on the log scale of a latent variable representing a threshold of detection distance. See Note for the relationship to the fitted parameters sigma and z.

For functions (8) and (18), 'G' is the cumulative distribution function of the gamma distribution with shape parameter \( k \) (\( = z \)) and scale parameter \( \theta \) (\( = \text{sigma}/z \)). See R’s pgamma.

For functions (9), (10) and (11), 'F' is the standard normal distribution function and \( c \) is an arbitrary signal threshold. The two parameters of (9) are functions of the parameters of (10) and (11): \( b_0 = (\beta_0 - c)/sdS \) and \( b_1 = \beta_1/s \) (see Efford et al. 2009). Note that (9) does not require signal-strength data or \( c \).

Function (11) includes an additional ‘hard-wired’ term for sound attenuation due to spherical spreading. Detection probability at distances less than 1 m is given by \( g(d) = 1 - F\{(c/\beta_0)/sdS \} \}

Functions (12) and (13) are undocumented methods for sound attenuation.

Function (19) has been used in some published papers and is included for comparison (see e.g. Ergon and Gardner 2014).

Function (20) assigns positive probability of detection only to points within a square pixel (cell) with side 2 sigma that is centred on the detector. (Typically used with fixed sigma = detector spacing \( l/2 \).)
Note

The parameters of function (7) are potentially confusing. The fitted parameters describe a latent threshold variable on the natural scale: sigma (mean) = \(\exp(\mu + s^2/2)\) and z (standard deviation) = \(\sqrt{\exp(s^2 + 2\mu)\exp(s^2) - 1}\). As with other detection functions, sigma is a spatial scale parameter, although in this case it corresponds to the mean of the threshold variable; the standard deviation of the threshold variable (z) determines the shape (roughly 1/max(slope)) of the detection function.

detector(object) <- value

Arguments

object object with ‘detector’ attribute e.g. traps  
value character string for detector type  
... other arguments (not used)
Details

Valid detector types are ‘single’, ‘multi’, ‘proximity’, ‘count’, ‘capped’, ‘signal’, ‘polygon’, ‘transect’, ‘polygonX’, and ‘transectX’. The detector type is stored as an attribute of a traps object. Detector types are mostly described by Efford et al. (2009a,b; see also secr-overview.pdf). Polygon and transect detector types are for area and linear searches as described in secr-polygondetectors.pdf and Efford (2011). The ‘signal’ detector type is used for acoustic data as described in secr-sound.pdf.

The ‘capped’ detector type refers to binary proximity data in which no more than one individual may be detected at a detector on any occasion. The type is partially implemented in secr 3.1.1: data may be simulated and manipulated, but for model fitting these are treated as proximity data by secr.fit().

Value

character string for detector type

References

See Also

traps, RShowDoc

Examples

```r
## Default detector type is "multi"
temptrap <- make.grid(nx = 6, ny = 8)
detector(temptrap) <- "proximity"
summary(temptrap)
```

deviance

Deviance of fitted secr model and residual degrees of freedom

Description

Compute the deviance or residual degrees of freedom of a fitted secr model, treating multiple sessions and groups as independent. The likelihood of the saturated model depends on whether the ‘conditional’ or ‘full’ form was used, and on the distribution chosen for the number of individuals observed (Poisson or binomial).
deviance

Usage

```r
## S3 method for class 'secr'
deviance(object, ...)
## S3 method for class 'secr'
df.residual(object, ...)
```

Arguments

- `object`: secr object from `secr.fit`
- `...`: other arguments (not used)

Details

The deviance is \(-2\log(\hat{L}) + 2\log(L_{sat})\), where \(\hat{L}\) is the value of the log-likelihood evaluated at its maximum, and \(L_{sat}\) is the log-likelihood of the saturated model, calculated thus:

Likelihood conditional on \(n\) -

\[
L_{sat} = \log(n!) + \sum_{\omega} n_{\omega} \log\left(\frac{n_{\omega}}{n}\right) - \log(n_{\omega}!)
\]

Full likelihood, Poisson \(n\) -

\[
L_{sat} = n \log(n) - n + \sum_{\omega} n_{\omega} \log\left(\frac{n_{\omega}}{n}\right) - \log(n_{\omega}!)
\]

Full likelihood, binomial \(n\) -

\[
L_{sat} = n \log\left(\frac{n}{N}\right) + (N - n) \log\left(\frac{N - n}{N}\right) + \log\left(\frac{N!}{(N-n)!}\right) + \sum_{\omega} n_{\omega} \log\left(\frac{n_{\omega}}{n}\right) - \log(n_{\omega}!)
\]

\(n\) is the number of individuals observed at least once, \(n_{\omega}\) is the number of distinct histories, and \(N\) is the number in a chosen area \(A\) that we estimate by \(\hat{N} = \hat{D}A\).

The residual degrees of freedom is the number of distinct detection histories minus the number of parameters estimated. The detection histories of two animals are always considered distinct if they belong to different groups.

When samples are (very) large the deviance is expected to be distributed as \(\chi^2\) with \(n_{\omega} - p\) degrees of freedom when \(p\) parameters are estimated. In reality, simulation is needed to assess whether a given value of the deviance indicates a satisfactory fit, or to estimate the overdispersion parameter \(c\). `sim.secr` is a convenient tool.

Value

The scalar numeric value of the deviance or the residual degrees of freedom extracted from the fitted model.

```

discretize Rasterize Area Search or Transect Data

Description

It is sometimes useful to re-cast area-search (polygon or polygonX) data as if it was from a set of closely spaced point detectors, i.e. to rasterize the detection locations. This function makes that conversion. Each polygon detector in the input is replaced by a number of point detectors, each representing a square pixel. Detections are mapped to the new detectors on the basis of their x-y coordinates.

If object contains transect data the problem is passed to `snip` and `reduce.capthist`.

Usage

```r
discretize(object, spacing = 5, outputdetector = c("proximity", "count", "multi"),
           tol = 0.001, cell.overlap = FALSE, type = c("centre", "any", "all"), ...)
```

Arguments

- `object`: secr capthist or traps object
- `spacing`: numeric spacing between point detectors in metres
- `outputdetector`: character output detector type
- `tol`: numeric fractional inflation of perimeter (see Details)
- `cell.overlap`: logical; if TRUE the area of overlap is stored in usage attribute
- `type`: character; see Details
- `...`: other arguments passed to `snip` if object is transect

Details

The input should have detector type `polygon` or `polygonX`.

A new array of equally spaced detectors is generated within each polygon of the input, inflated radially by `1 + tol` to avoid some inclusion problems. The origin of the superimposed grid is fixed automatically. If `type = "centre"` detectors are included if they lie within the (inflated) polygon. Otherwise, the decision on whether to include a candidate new detector is based on the corner vertices of the cell around the detector (`side = spacing`); `type = "any"` and `type = "all"` have the obvious meanings.
tol may be negative, in which case the array(s) will be shrunk relative to the polygon(s).

For irregular polygons the edge cells in the output may be only partially contained within the polygon they represent. Set `cell.overlap = TRUE` to retain the proportion of overlap as the ‘usage’ of the new traps object. This can take a few seconds to compute. If ‘usage’ is already defined then the new ‘usage’ is the old multiplied by the proportion of overlap.

Combining `type = "any"` and `cell.overlap = TRUE` with `tol > 0` can have the odd effect of including some marginal detectors that are assigned zero usage.

With `type = "any"`, the sum of the overlap proportions times cell area is equal to the area of the polygons.

**Value**

A capthist or traps object of the requested detector type, but otherwise carrying forward all attributes of the input. The embedded traps object has a factor covariate ‘polyID’ recording the polygon to which each point detector relates.

**Note**

Consider the likely number of detectors in the output before you start.

**See Also**

`reduce.capthist`, `snip`

**Examples**

```r
## Not run:
## generate some polygon data
pol <- make.poly()
CH <- sim.capthist(pol, popn = list(D = 30), detectfn = 'HHN',
                   detectpar = list(lambda0 = 0.3))
plot(CH, border = 10, gridl = FALSE, varycol = FALSE)

## discretize and plot
CH1 <- discretize(CH, spacing = 10, output = 'count')
plot(CH1, add = TRUE, cappar = list(col = 'orange'), varycol = FALSE, rad = 0)
plot(traps(CH1), add = TRUE)
# overlay cell boundaries
plot(as.mask(traps(CH1)), dots = FALSE, col = NA, meshcol = 'green',
     add = TRUE)

## show how detections are snapped to new detectors
newxy <- traps(CH1)[nearesttrap(xy(CH),traps(CH1)),]
segments(xy(CH)[,1], xy(CH)[,2], newxy[,1], newxy[,2])

plot(traps(CH), add = TRUE) # original polygon
```
## Incomplete overlap

```r
pol <- rotate(make.poly(), 45)
CH2 <- sim.capthist(pol, popn = list(D = 30), detectfn = 'HHN',
                      detectpar = list(lambda0 = 0.3))
plot(CH2, border = 10, gridl = FALSE, varycol = FALSE)
CH3 <- discretize(CH2, spacing = 10, output = 'count', type = 'any',
                      cell.overlap = TRUE, tol=0.05)
plot(CH3, add = TRUE, cappar = list(col = 'orange'), varycol =
     FALSE, rad = 0)
plot(traps(CH3), add = TRUE)
```

# overlay cell boundaries and usage
```r
msk <- as.mask(traps(CH3))
covariates(msk) <- data.frame(usage = usage(traps(CH3))[,1])
plot(msk, dots = FALSE, cov='usage', meshcol = 'green',
     add = TRUE)
```

## End(Not run)

---

### distancetotrap

**Distance To Nearest Detector**

**Description**

Compute Euclidean distance from each of a set of points to the nearest detector in an array, or return the sequence number of the detector nearest each point.

**Usage**

```r
distancetotrap(X, traps)
nearesttrap(X, traps)
```

**Arguments**

- `X` coordinates
- `traps` traps object or 2-column matrix of coordinates

**Details**

distancetotrap returns the distance from each point in `X` to the nearest detector in `traps`. It may be used to restrict the points on a habitat mask.

For traps objects with polygon detector type (polygon, polygonX), and for SpatialPolygons, the function sf::st_distance is used internally(from secr 4.5.2).
Value

distancetotrap returns a vector of distances (assumed to be in metres).

nearesttrap returns the index of the nearest trap.

See Also

make.mask

Examples

## restrict a habitat mask to points within 70 m of traps
## this is nearly equivalent to using make.mask with the
## 'trapbuffer' option
# temptrap <- make.grid()
tempmask <- make.mask(temptrap)
d <- distancetotrap(tempmask, temptrap)
tempmask <- subset(tempmask, d < 70)

---

Dsurface  Density Surfaces

Description

S3 class for rasterized fitted density surfaces. A Dsurface is a type of ‘mask’ with covariate(s) for
the predicted density at each point.

Usage

## S3 method for class 'Dsurface'
print(x, scale = 1, ...)
## S3 method for class 'Dsurface'
summary(object, scale = 1, ...)

Arguments

  x, object  Dsurface object to display
  scale  numeric multiplier for density
  ...  other arguments passed to print method for data frames or summary method for masks
Details

A Dsurface will usually have been constructed with **predictDsurface**.

The ‘scale’ argument may be used to change the units of density from the default (animals / hectare) to animals / km\(^2\) (scale = 100) or animals / 100km\(^2\) (scale = 10000).

A virtual S4 class ‘Dsurface’ is defined to allow the definition of a method for the generic function `raster` from the **raster** package.

### ellipse.secr

**Confidence Ellipses**

#### Description

Plot joint confidence ellipse for two parameters of secr model, or for a distribution of points.

#### Usage

```r
ellipse.secr(object, par = c("g0", "sigma"), alpha = 0.05,
             npts = 100, plot = TRUE, linkscale = TRUE, add = FALSE,
             col = palette(), ...)
ellipse.bvn(xy, alpha = 0.05, npts = 100, centroid = TRUE, add = FALSE, ...)
```

#### Arguments

- **object** secr object output from **secr.fit**
- **par** character vector of length two, the names of two ‘beta’ parameters
- **alpha** alpha level for confidence intervals
- **npts** number of points on perimeter of ellipse
- **plot** logical for whether ellipse should be plotted
- **linkscale** logical; if FALSE then coordinates will be backtransformed from the link scale
- **add** logical to add ellipse to an existing plot
- **col** vector of one or more plotting colours
- **...** arguments to pass to plot functions (or polygon() in the case of ellipse.bvn)
- **xy** 2-column matrix of coordinates
- **centroid** logical; if TRUE the plotted ellipse is a confidence region for the centroid of points in **xy**
Details

calculate coordinates of a confidence ellipse from the asymptotic variance-covariance matrix of the beta parameters (coefficients), and optionally plots it.

If linkscale == FALSE, the inverse of the appropriate link transformation is applied to the coordinates of the ellipse, causing it to deform.

If object is a list of secr models then one ellipse is constructed for each model. Colours are recycled as needed.

calculates coordinates of a confidence ellipse for the centroid of a 2-dimensional distribution of points (default centroid = TRUE), or a Jennrich and Turner (1969) elliptical home-range model.

Value

A list containing the x and y coordinates is returned invisibly from either function.

References

Examples

calculation coordinates of a confidence ellipse for the centroid of a 2-dimensional distribution of points (default centroid = TRUE), or a Jennrich and Turner (1969) elliptical home-range model.

alpha = 0.05, loginterval = TRUE)

derivedCluster ( object, method = c("SRS", "R2", "R3", "local", "poisson", "binomial"),
alpha = 0.05, loginterval = TRUE)

derivedSession ( object, method = c("SRS", "R2", "R3", "local", "poisson", "binomial"),
xy = NULL, alpha = 0.05, loginterval = TRUE, area = NULL, independent.esa = FALSE )

derivedExternal ( object, sessnum = NULL, nj, cluster, buffer = 100,
mask = NULL, noccasions = NULL, method = c("SRS", "local"), xy = NULL,
alpha = 0.05, loginterval = TRUE)

derivedSystematic( object, xy, design = list(), basenx = 10, df = 9, extrapolate = TRUE,
alpha = 0.05, loginterval = TRUE, independent.esa = FALSE, keep = FALSE, ncores = NULL)

Arguments

object fitted secr model
nj vector of number observed in each sampling unit (cluster)
esa estimate of effective sampling area (\(\hat{a}\))
se.esa estimated standard error of effective sampling area (\(\hat{SE}(\hat{a})\))
method character string 'SRS' or 'local'
xy dataframe of x- and y- coordinates (method = "local" only)
alpha alpha level for confidence intervals
loginterval logical for whether to base interval on log(N)
area area of region for method = "binomial" (hectares)
independent.esa logical; controls variance contribution from esa (see Details)
sessnum index of session in object$capthist for which output required
cluster ‘traps’ object for a single cluster
buffer width of buffer in metres (ignored if mask provided)
mask mask object for a single cluster of detectors
noccasions number of occasions (for nj)
design list specifying systematic design (see Details)
basenx integer number of basis grid points in x-dimension
df integer number of degrees of freedom for gam
extrapolate logical; if FALSE then boxlet p values are inferred from nearest point inside
convex hull of grid
keep logical; if TRUE then derivedSystematic saves key intermediate values as attributes
ncores integer
Details

derivednj accepts a vector of counts (nj), along with \( \hat{a} \) and \( \hat{SE}(\hat{a}) \). The argument esa may be a scalar or (if se.esa is NULL) a 2-column matrix with \( \hat{a}_j \) and \( \hat{SE}(\hat{a}_j) \) for each replicate j (row). In the special case that nj is of length 1, or method takes the values ‘poisson’ or ‘binomial’, the variance is computed using a theoretical variance rather than an empirical estimate. The value of method corresponds to ‘distribution’ in derived, and defaults to ‘poisson’. For method = ‘binomial’ you must specify area (see Examples).

If independent.esa is TRUE then independence is assumed among cluster-specific estimates of esa, and esa variances are summed. The default is a weighted sum leading to higher overall variance.

derivedCluster accepts a model fitted to data from clustered detectors; each cluster is interpreted as a replicate sample. It is assumed that the sets of individuals sampled by different clusters do not intersect, and that all clusters have the same geometry (spacing, detector number etc.).

derivedMash accepts a model fitted to clustered data that have been ‘mashed’ for fast processing (see mash); each cluster is a replicate sample: the function uses the vector of cluster frequencies \( n_j \) stored as an attribute of the mashed capthist by mash.

derivedExternal combines detection parameter estimates from a fitted model with a vector of frequencies \( n_j \) from replicate sampling units configured as in cluster. Detectors in cluster are assumed to match those in the fitted model with respect to type and efficiency, but sampling duration (noccasions), spacing etc. may differ. The mask should match cluster; if mask is missing, one will be constructed using the buffer argument and defaults from make.mask.

derivedSession accepts a single fitted model that must span multiple sessions; each session is interpreted as a replicate sample.

Spatial variance is calculated by one of these methods

<table>

</tbody>
</table>

The weighted options R2 and R3 substitute \( \hat{a}_j \) for line length \( l_k \) in the corresponding formulae of Fewster et al. (2009, Eq 3.5). Density is estimated by \( D = n/A \) where \( A = \sum a_j \). The variance of \( A \) is estimated as the sum of the cluster-specific variances, assuming independence among clusters. Fewster et al. (2009) found that an alternative estimator for line transects derived by Thompson (2002) performed better when there were strong density gradients correlated with line length (R2 in Fewster et al. 2009, Eq 3).

The neighborhood variance estimator is implemented in package spsurvey and was originally proposed for generalized random tessellation stratified (GRTS) samples. For ‘local’ variance estimates, the centre of each replicate must be provided in xy, except where centres may be inferred from the data. It is unclear whether ‘local’ can or should be used when clusters vary in size.

derivedSystematic implements the ‘boxlet’ variance estimator of Fewster (2011) for systematic designs using clustered detectors (an alternative to derivedCluster and derivedSessions). The
The ‘design’ argument is a list with components corresponding to arguments of `make.systematic`, (\(n\) and \(\text{origin}\) are ignored if provided):

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster</td>
<td>traps object for a single cluster</td>
</tr>
<tr>
<td>region</td>
<td>2-column matrix or SpatialPolygons</td>
</tr>
<tr>
<td>spacing</td>
<td>spacing between cluster origins</td>
</tr>
<tr>
<td>...</td>
<td>other arguments passed to <code>trap.builder</code></td>
</tr>
<tr>
<td>e.g. edgemethod, exclude, exclmethod</td>
<td></td>
</tr>
</tbody>
</table>

If `region` is omitted from `design` then an attempt will be made to retrieve it from the mask attribute of object (this works if the call to `make.mask` used `keep.poly = TRUE`).

### Value

Dataframe with one row for each derived parameter (‘esa’, ‘D’) and columns as below:

- `estimate`: estimate of derived parameter
- `SE.estimate`: standard error of the estimate
- `lcl`: lower 100(1–\(\alpha\))\% confidence limit
- `ucl`: upper 100(1–\(\alpha\))\% confidence limit
- `CVn`: relative SE of number observed (across sampling units)
- `CVa`: relative SE of effective sampling area
- `CVD`: relative SE of density estimate

### Note

The variance of a Horvitz-Thompson-like estimate of density may be estimated as the sum of two components, one due to uncertainty in the estimate of effective sampling area (\(\hat{a}\)) and the other due to spatial variance in the total number of animals \(n\) observed on \(J\) replicate sampling units (\(n = \sum_{j=1}^{J} n_j\)). We use a delta-method approximation that assumes independence of the components:

\[
\hat{\text{var}}(\hat{D}) = \hat{D}^2 \left\{ \frac{\text{var}(n)}{n^2} + \frac{\text{var}(\hat{a})}{\hat{a}^2} \right\}
\]

where \(\text{var}(n) = \sum_{j=1}^{J} (n_j - n/J)^2\). The estimate of \(\text{var}(\hat{a})\) is model-based while that of \(\text{var}(n)\) is design-based. This formulation follows that of Buckland et al. (2001, p. 78) for conventional distance sampling. Given sufficient independent replicates, it is a robust way to allow for unmodelled spatial overdispersion.

There is a complication in SECR owing to the fact that \(\hat{a}\) is a derived quantity (actually an integral) rather than a model parameter. Its sampling variance \(\text{var}(\hat{a})\) is estimated indirectly in `secr` by combining the asymptotic estimate of the covariance matrix of the fitted detection parameters \(\theta\) with a numerical estimate of the gradient of \(a(\theta)\) with respect to \(\theta\). This calculation is performed in `derived`.

### Mask Buffer Diagnostic Plot

**Description**

Plot effective sampling area (Borchers and Efford 2008) as a function of increasing buffer width.

**Usage**

```r
esa.plot (object, max.buffer = NULL, spacing = NULL, max.mask = NULL,
          detectfn, detectpar, nooccasions, binomN = NULL, thin = 0.1,
          poly = NULL, poly.habitat = TRUE, session = 1, plt = TRUE,
          type = c('density', 'esa', 'meanpdot', 'CVpdot'), n = 1, add = FALSE,
          overlay = TRUE, conditional = FALSE, ...)
```

**Arguments**

- `object` traps object or secr object output from secr.fit
- `max.buffer` maximum width of buffer in metres
- `spacing` distance between mask points
- `max.mask` mask object
**esa.plot**

</tbody>
</table>

**Details**

Effective sampling area (esa) is defined as the integral of net capture probability \(p(X)\) over a region. esa.plot shows the effect of increasing region size on the value of esa for fixed values of the detection parameters. The max.buffer or max.mask arguments establish the maximum extent of the region; points (cells) within this mask are sorted by their distance \(d_k\) from the nearest detector. esa(buffer) is defined as the cumulative sum of \(cp(X)\) for \(d_k(X) \leq buffer\), where \(c\) is the area associated with each cell.

The default (type = 'density') is to plot the reciprocal of esa multiplied by \(n\); this is on a more familiar scale (the density scale) and hence is easier to interpret.

Because esa.plot uses the criterion 'distance to nearest detector', max.mask should be constructed to include all habitable cells within the desired maximum buffer and no others. This is achieved with type = "trapbuffer" in make.mask. It is a good idea to set the spacing argument of make.mask rather than relying on the default based on nx. Spacing may be small (e.g. sigma/10) and the buffer of max.mask may be quite large (e.g. 10 sigma), as computation is fast.

Thinning serves to reduce redundancy in the plotted points, and (if the result is saved and printed) to generate more legible numerical output. Use thin=1 to include all points.

esa.plot calls the internal function esa.plot.secr when object is a fitted model. In this case detectfn, detectpar and nooccasions are inferred from object.

**Value**

A dataframe with columns

- buffer: buffer width
esa: computed effective sampling area
density: n/esa
pdot: \( p(X) \)
pdotmin: cumulative minimum \( (p(X)) \)
meandpdot: expected pdot across mask (see CVpdot)
CVpdot: CV of pdot across mask (see CVpdot)

If plt = TRUE the dataframe is returned invisibly.

**Note**

The response of effective sampling area to buffer width is just one possible mask diagnostic; it’s fast, graphic, and often sufficient. mask.check performs more intensive checks, usually for a smaller number of buffer widths.

The old argument 'as.density' was superceded by 'type' in 3.1.7.

**References**

**See Also**

mask, pdot, CVpdot, make.mask, mask.check, Detection functions

**Examples**

```r
## Not run:

## with previously fitted model
esa.plot(secrdemo.0)

## from scratch
tbps <- make.grid()
msk <- make.mask(trp, buffer = 200, spacing = 5, type = "trapbuffer")
detectpar <- list(g0 = 0.2, sigma = 25)
esa.plot(trps, msk, 0, detectpar, nocc = 10, col = "blue")
esa.plot(trps, msk, 0, detectpar, nocc = 5, col = "green",
         add = TRUE)

esa.plot(trps, msk, 0, detectpar, nocc = 5, thin = 0.002, plt = FALSE)

## End(Not run)
```
**esa.plot.secr**

**Mask Buffer Diagnostic Plot (internal)**

### Description

Internal function used to plot effective sampling area (Borchers and Efford 2008) as a function of increasing buffer width given an `secr` object.

### Usage

```r
esa.plot.secr(object, max.buffer = NULL, max.mask = NULL, thin = 0.1, poly = NULL, poly.habitat = TRUE, session = 1, plt = TRUE, type = "density", add = FALSE, overlay = TRUE, conditional = FALSE, ...)
```

### Arguments

- `object`: secr object output from `secr.fit`
- `max.buffer`: maximum width of buffer in metres
- `max.mask`: mask object
- `thin`: proportion of mask points to retain in plot and output
- `poly`: matrix of two columns interpreted as the x and y coordinates of a bounding polygon (optional)
- `poly.habitat`: logical as in `make.mask`
- `session`: vector of session indices (used if `object` spans multiple sessions)
- `plt`: logical to plot results
- `type`: character; see `esa.plot`
- `add`: logical to add line to an existing plot
- `overlay`: logical; if TRUE then automatically add = TRUE for plots after the first
- `conditional`: logical; see `esa.plot`
- `...`: graphical arguments passed to `plot()` and `lines()`

### Details

`esa.plot.secr` provides a wrapper for `esa.plot` that is called internally from `esa.plot` when it is presented with an `secr` object. Arguments of `esa.plot` such as `detectfn` are inferred from the fitted model.

If `max.mask` is not specified then a maximal mask of type `trapbuffer` is constructed using `max.buffer` and the spacing of the mask in `object`. In this case, if `max.buffer` is not specified then it is set either to the width of the existing plot (add = TRUE) or to 10 x sigma-hat from the fitted model in `object` (add = FALSE).
expected.n

Value

see esa.plot

See Also

esa.plot, mask, pdot, make.mask, mask.check, Detection functions

descriptions

Description

Computes the expected number of individuals detected across a detector layout or at each cluster of detectors.

Usage

expected.n(object, session = NULL, group = NULL, bycluster = FALSE, splitmask = FALSE, ncores = NULL)

Arguments

object secr object output from secr.fit
session character session vector
group group – for future use
bycluster logical to output the expected number for clusters of detectors rather than whole array
splitmask logical for computation method (see Details)
ncores integer number of threads to be used for parallel processing

Details

The expected number of individuals detected is \( E(n) = \int p(X)D(X)dx \) where the integration is a summation over object$mask. \( p(X) \) is the probability an individual at \( X \) will be detected at least once either on the whole detector layout (bycluster = FALSE) or on the detectors in a single cluster (see pdot for more on \( p \)). \( D(X) \) is the expected density at \( X \), given the model. \( D(X) \) is constant (i.e. density surface flat) if object$CL == TRUE or object$model$D == ~1, and for some other possible models.

If the bycluster option is selected and detectors are not, in fact, assigned to clusters then each detector will be treated as a cluster, with a warning.

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).
By default, a full habitat mask is used for each cluster. This is the more robust option. Alternatively, the mask may be split into subregions defined by the cells closest to each cluster.

The calculation takes account of any fitted continuous model for spatial variation in density (note Warning).

Value

The expected count (bycluster = FALSE) or a vector of expected counts, one per cluster. For multi-session data, a list of such vectors.

Warning

This function changed slightly between 2.1.0 and 2.1.1, and now performs as indicated here when bycluster = TRUE and clusters are not specified.

Clusters of detectors are assumed to be independent (always true with detector types ‘proximity’, ‘count’ etc.). The computed E(n) does not apply when there is competition among clusters of detectors.

The prediction of density at present considers only the base level of density covariates, such as cell-specific habitat variables.

region.N

Examples

```r
## Not run:
expected.n(secrdemo.0)
expected.n(secrdemo.0, bycluster = TRUE)
expected.n(ovenbird.model.D)

## Clustered design
mini <- make.grid(nx = 3, ny = 3, spacing = 50, detector = "proximity")
tempgrids <- trap.builder (cluster = mini, method = "all",
    frame = expand.grid(x = seq(1000, 9000, 2000),
    y = seq(1000, 9000, 2000)), plt = TRUE)
capt <- sim.capthist(tempgrids, popn = list(D = 2))
tempmask <- make.mask(tempgrids, buffer = 100,
    type = "clusterbuffer")
fit <- secr.fit(capt, mask = tempmask, trace = FALSE)
En <- expected.n(fit, bycluster = TRUE)

## GoF or overdispersion statistic
p <- length(fit$fit$par)
y <- cluster.counts(capt)
## scaled by n-p
sum((y - En)^2 / En) / (length(En)-p)
```
```r
\[
\text{sum((y - En)^2 / En)} / \text{sum}(y/En)
\]
```

```r
## End(Not run)
```

### extractMoves

**Simulated Movements**

**Description**

Extract movements from a previously simulated multi-session population.

**Usage**

```r
effectsMoves(pop, plotn = NULL, add = FALSE, collapse = TRUE, maxradius = Inf, ...)
```

**Arguments**

- `pop` : popn object from `sim.popn`
- `plotn` : integer maximum number of instances to plot at each session
- `add` : logical for whether to add to existing plot
- `collapse` : logical; if TRUE plots for sessions 2, 3,... are added to the first
- `maxradius` : numeric radius for selecting subset of initial locations
- `...` : arguments passed to `arrows`

**Details**

This function is mostly used to check the movement simulations.

Moves are constrained by the edge (argument ‘edgemethod’ of `sim.popn`). ‘maxradius’ may be set to restrict the extraction to the subset of animals initially near the centroid of the arena in each session.

Plotting uses the graphics function `arrows` that has some quirks, such as difficult-to-suppress warnings for zero-length moves. Set `code = 0` to suppress arrowheads; `length = 0.1` to shorten to 0.1 inches, etc.

**Value**

List of data frames, one for each session but the last (columns ‘x1’, ‘y1’, ‘x2’, ‘y2’, ‘d’).

**See Also**

`turnover`, `sim.popn`
Examples

```r
set.seed(12345)
pop3 <- sim.popn(D = 2, core = make.grid(), buffer = 200, nsessions = 3,
                 details = list(lambda = 1.0, movemodel = 'BVE', move.a = 50,
                                edgemethod = 'stop'))
m <- extractMoves(pop3, plotn = 10, length = 0.1)
mean(unlist(sapply(m, ['-', 'd'])))) # less than nominal 2 x move.a

# For distances closer to nominal for BVE (2 x move.a = 100),
# increase size of arena (e.g., buffer = 500) and consider only
# central animals (e.g., maxradius = 300).
```

FAQ

Frequently Asked Questions, And Others

Description

A place for hints and miscellaneous advice.

How do I install and start secr?

Follow the usual procedure for installing from CRAN archive (see menu item Packages | Install package(s)... in Windows). You also need to get the package abind from CRAN.

Other required packages (MASS, nlme, stats) should be available as part of your R installation. Like other contributed packages, secr needs to be loaded before each use e.g., library(secr).

You can learn about changes in the current version with news(package = "secr").

How can I get help?

There are three general ways of displaying documentation from within R. Firstly, you can bring up help pages for particular functions from the command prompt. For example:

?secr or ?secr.fit

Secondly, help.search() lets you ask for a list of the help pages on a vague topic (or just use ?? at the prompt). For example:

?? "linear models"

Thirdly, you can display various secr documents listed in secr-package.

Tip: to search all secr help pages open the pdf version of the manual in Acrobat Reader (secr-manual.pdf; see also ?secr) and use <ctrl> F.

There is a support forum at http://www.phidot.org/forum/ under ‘DENSITY|secr’ and another at secrforum. See below for more R tips. Some specific problems with secr.fit are covered in Troubleshooting.
How should I report a problem?

If you get really stuck or find something you think is a bug then please report the problem to one of the online lists.

You may be asked to send an actual dataset - ideally, the simplest one that exhibits the problem. Use `save` to wrap several R objects together in one .RData file, e.g., `save("captdata", "secrdemo.0", "secrdemo.b", file = "mydata.RData")`. Also, paste into the text of your message the output from `packageDescription("secr")`.

Why do I get different answers from secr and Density?

Strictly speaking, this should not happen if you have specified the same model and likelihood, although you may see a little variation due to the different maximization algorithms. Likelihoods (and estimates) may differ if you use different integration meshes (habitat masks), which can easily happen because the programs differ in how they set up the mesh. If you want to make a precise comparison, save the Density mesh to a file and read it into secr, or vice versa.

Extreme data, especially rare long-distance movements, may be handled differently by the two programs. The ‘minprob’ component of the ‘details’ argument of `secr.fit` sets a lower threshold of probability for capture histories (smaller values are all set to minprob), whereas Density has no explicit limit.

How can I speed up model fitting and model selection?

There are many ways - see Speed tips and secr-troubleshooting.pdf.

Does secr use multiple cores?

Some computations can be run in parallel on multiple processors (most desktops these days have multiple cores). Likelihood calculations in `secr.fit` assign capture histories to multiple parallel threads whenever possible.

Can a model use detector-level covariates that vary over time?

Yes. See `?timevaryingcov`. However, a more direct way to control for varying effort is provided - see the ‘usage’ attribute, which now allows a continuous measure of effort (secr-varyingeffort.pdf). A tip: covariate models fit more quickly when the covariate takes only a few different values.

Things You Might Need To Know About R

The function `findFn` in package `sos` lets you search CRAN for R functions by matching text in their documentation.

There is now a vast amount of R advice available on the web. For the terminally frustrated, ‘R inferno’ by Patrick Burns is recommended (`https://www.burns-stat.com/pages/Tutor/R_inferno.pdf`). “If you are using R and you think you’re in hell, this is a map for you”.

Method functions for S3 classes cannot be listed in the usual way by typing the function name at the R prompt because they are ‘hidden’ in a namespace. Get around this with `getAnywhere()`. For example:

```r
getAnywhere(print.secr)
```
R objects have ‘attributes’ that usually are kept out of sight. Important attributes are ‘class’ (all objects), ‘dim’ (matrices and arrays) and ‘names’ (lists). secr hides quite a lot of useful data as named ‘attributes’. Usually you will use summary and extraction methods (traps, covariates, usage etc.) to view and change the attributes of the various classes of object in secr. If you’re curious, you can reveal the lot with ‘attributes’. For example, with the demonstration capture history data ‘captdata’:

traps(captdata) ## extraction method for 'traps'
attributes(captdata) ## all attributes

Also, the function str provides a compact summary of any object:

str(captdata)

---

Fletcher.chat Estimate overdispersion

### Description
General function for estimating a variance inflation factor (\( \hat{c} \)) from observed counts.

### Usage

Fletcher.chat (observed, expected, np, verbose = TRUE, 
  type = c('Fletcher', 'Wedderburn', 'both'), multinomial = FALSE)

### Arguments

- **observed**: integer vector of observed counts, or a list of such vectors
- **expected**: numeric vector of expected counts
- **np**: integer number of parameters estimated
- **verbose**: logical; if TRUE returns extended output
- **type**: character
- **multinomial**: logical; if TRUE, one df is subtracted for the constraint

### Details

Fletcher.chat applies the overdispersion formula of Fletcher (2012) or computes the conventional (Wedderburn 1974) variance inflation factor \( X^2/\text{df} \). It is used by chat.nk and adjustVarD. The inputs ‘observed’ and ‘expected’ are vectors of counts (e.g., number of distinct individuals per detector); ‘observed’ may also be a list of such vectors, possibly simulated.
Value

Output depends on `verbose`, `observed` and `type`:

– if `observed` is a list of nk vectors (usually generated by simulation) then the output is a vector of (Fletcher or Wedderburn) \( \hat{c} \) values, one element for each component of `observed`, unless type = "both" when the output is a list of two such vectors. Argument `verbose` is ignored.

– if `observed` is a simple vector then `verbose` output is a list comprising input values, various summary statistics, and the computed Fletcher overdispersion (`chat`). The statistic `cX2` is the conventional variance inflation factor of Wedderburn (1974) – \( X^2/df \). For `verbose = FALSE`, a single estimate of \( \hat{c} \) is returned when `type = "Fletcher"` or `type = "Wedderburn"`, otherwise a vector of the two estimates.

References

`chat.nk`, `adjustVarD`
Details

This function calls \texttt{fxi.secr} for each detected animal and overlays the results to obtain a summed probability density surface \( D.fx \) for the locations of the home-range centres of detected individuals.

A separate calculation using \texttt{pdot} provides the expected spatial distribution of undetected animals, as another density surface: crudely, \( D.nc(X) = D(X) \times (1 - \text{pdot}(X)) \).

The pointwise sum of the two surfaces is sometimes used to represent the spatial distribution of the population, but see Notes.

Setting \texttt{ncores = NULL} uses the existing value from the environment variable \texttt{RCPP\_PARALLEL\_NUM\_THREADS} (see \texttt{setNumThreads}).

Value

An object of class ‘\texttt{Dsurface}’ (a variety of mask) with a ‘covariates’ attribute that is a dataframe with columns –

- \( D.fx \): sum of \texttt{fxi} over all detected individuals
- \( D.nc \): expected density of undetected (‘not caught’) individuals
- \( D.sum \): sum of \( D.fx \) and \( D.nc \)

All densities are in animals per hectare (the ‘scale’ argument of \texttt{plot.Dsurface} allows the units to be varied later).

Note

The surface \( D.sum \) represents what is known from the data about a specific realisation of the spatial point process for home range centres: varying the intensity of sampling will change its shape. It is not an unbiased estimate of a biologically meaningful density surface. The surface will always tend to lack relief towards the edge of a habitat mask where the main or only contribution is from \( D.nc \).

Examples

```r
## Not run:
tmp <- fx.total(secr.demo.0)

## to plot we must name one of the covariates:
## the \texttt{Dsurface} default ‘\texttt{D.0}’ causes an error
plot(tmp, covariate = ‘D.sum’, col = terrain.colors(16),
```
```r
plottype = 'shaded'
plot(tmp, covariate = 'D.sum', col = 'white', add = TRUE,
plottype = 'contour')
if (interactive()) {
  spotHeight(tmp, prefix = 'D.sum')
}

fxsurface <- fx.total(ovenbird.model.D, sessnum = 3)
plot(fxsurface, covariate = 'D.sum')

## End(Not run)
```

---

## fxi

### Probability Density of Home Range Centre

**Description**

Display contours of the probability density function for the estimated location of one or more range centres, compute values for particular points X, or compute mode of pdf. The pdf is given by $f(X_j|\omega_i) = \Pr(\omega_i|X_j)\pi(X_j)$, where $\pi(X)$ is the probability density of range centres across the mask (Borchers and Efford 2008).

**Usage**

```r
fxi.contour(object, i = 1, sessnum = 1, border = 100, nx = 64,
  levels = NULL, p = seq(0.1,0.9,0.1), plt = TRUE, add = FALSE,
  fitmode = FALSE, plotmode = FALSE, fill = NULL,
  output = c('list','sf','SPDF'), ncores = NULL, ...)
fxi.secr(object, i = NULL, sessnum = 1, X = NULL, ncores = NULL)
fxi.mode(object, i = 1, sessnum = 1, start = NULL, ncores = NULL, ...)
```

**Arguments**

- **object**: a fitted secr model
- **i**: integer or character vector of individuals (defaults to all in fxi.secr), or a single individual as input to fxi.mode
- **sessnum**: session number if object$capthist spans multiple sessions
- **border**: width of blank margin around the outermost detectors
- **nx**: dimension of interpolation grid in x-direction
- **levels**: numeric vector of confidence levels for $\Pr(X|\omega_i)$
- **p**: numeric vector of contour levels as probabilities
- **plt**: logical to plot contours
- **add**: logical to add contour(s) to an existing plot
fitmode logical to refine estimate of mode of each pdf
plotmode logical to plot mode of each pdf
X 2-column matrix of x- and y- coordinates (defaults to mask)
fill vector of colours to fill contours (optional)
output character; format of output (list, sf or SpatialPolygonsDataFrame)
ncores integer number of threads to be used for parallel processing
start vector of x-y coordinates for maximization
... additional arguments passed to contour or nlm

Details

fxi.contour computes contours of probability density for one or more detection histories. Increase nx for smoother contours. If levels is not set, contour levels are set to approximate the confidence levels in p.

fxi.secr computes the probability density for one or more detection histories; X may contain coordinates for one or several points; a dataframe or vector (x then y) will be coerced to a matrix.

fxi.mode attempts to find the x- and y-coordinates corresponding to the maximum of the pdf for a single detection history (i.e. i is of length 1). fxi.mode calls nlm.

fxi.contour with fitmode = TRUE calls fxi.mode for each individual. Otherwise, the reported mode is an approximation (mean of coordinates of highest contour).
If i is character it will be matched to row names of object$capthist (restricted to the relevant session in the case of a multi-session fit); otherwise it will be interpreted as a row number.

Values of the pdf are normalised by dividing by the integral of Pr(ω | X)π(X) over the habitat mask in object. (May differ in secr 4.0).

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).

If start is not provided to fit.mode then (from 2.9.4) the weighted mean of all detector sites is used (see Warning below).
The ... argument gives additional control over a contour plot; for example, set drawlabels = FALSE to suppress contour labels.

Value

fxi.contour (output = 'list') –
Coordinates of the plotted contours are returned as a list with one component per polygon. The list is returned invisibly if plt = TRUE.
An additional component ‘mode’ reports the x-y coordinates of the highest point of each pdf (see Details).

fxi.contour (output = 'SPDF') –
Contours are returned as a SpatialPolygonsDataFrame (see package sp) with one component per animal. The attributes dataframe has two columns, the x- and y-coordinates of the mode. The SpatialPolygonsDataFrame is returned invisibly if plt = TRUE.

fxi.contour (output = 'sf') – simple features ‘sf’ object, as for SPDF.
fxi.secr –
Vector of probability densities

fxi.mode –
List with components ‘x’ and ‘y’

Warnings

fxi.mode may fail to find the true mode unless a good starting point is provided. Note that the
distribution may have multiple modes and only one is reported. The default value of start before
secr 2.9.4 was the first detected location of the animal.

Note

From secr 2.8.3, these functions work with both homogeneous and inhomogeneous Poisson density
models, and fxi.secr accepts vector-valued i.

See fxi.total for a surface summed across individuals.

**gridCells** *Construct Grid Cells*

**Description**

Forms grid cells centred on input points.

**Usage**

```r
gridCells(x, cellsize = spacing(x), crs = NA)
```

**Arguments**

- `x`  
  matrix or dataframe with x- and y-coordinates
- `cellsize`  
  length of gridcell side
- `crs`  
  crs description suitable for `st_crs`

**Details**

The argument `x` will often be a traps or mask object with spacing attribute. Otherwise `cellsize` must be provided.

**Value**

A simple features (sf) object of class ‘sfc_MULTIPOLYGON’.  
`crs` may be the integer EPSG code (e.g. 3578 Yukon Albers).

plot(traps(captdata), add = TRUE)

---

**hcov**

**Hybrid Mixture Model**

Description

The argument `hcov` in `secr.fit` is used to fit a hybrid mixture model. 'Hybrid' refers to a flexible combination of latent classes (as in a finite mixture) and known classes (cf groups or sessions). A hybrid mixture model includes a parameter ‘pmix’ for the mixing proportion and optionally allows detection parameters to be modelled as class-specific ( ~ h2). This is particularly useful for modelling sex ratio and sex differences in detection, and matches the Bayesian sex-specific model of Gardner et al. (2010).

For observed animals all of unknown class the model is identical to a finite mixture (i.e. latent-class) model. For observed animals all of known class, the classes are no longer ‘latent’ and the model is equivalent to a grouped model with an additional binomial factor for class membership.

Assumptions

`hcov` identifies a single individual covariate (the class covariate) that should be a factor with two levels, or contain character values that will be coerced to a factor (e.g., ‘f’, ‘m’). Missing values (NA) are used for individuals of unknown class. If `hcov` has more than two levels, all but the first two levels are converted to NA (but see exception for h3 models below).

It is assumed that the probability of recording a missing value for the class covariate is independent of the true class membership (e.g., sex equally likely to be recorded for males and females).

Operational details

A hybrid mixture model is fitted whenever `hcov` is not NULL. Mixture models include a parameter ‘pmix’, the mixing proportion. If the covariate identified by `hcov` is missing (‘’ or NA) for all individuals and a mixture term (h2 or h3) appears in the detection model (e.g., g0 ~ h2) then a conventional finite mixture model is fitted (cf Pledger 2000, Borchers & Efford 2008).

As with finite mixture models, any detection parameter (g0, sigma etc.) may be modelled as depending on mixture class by model specifications such as (g0 ~ h2, sigma ~ h2). See Examples.

In general `hcov` has been designed for two classes and two classes are assumed if neither ‘h2’ nor ‘h3’ appears in the model formulae. However, there is a small exception: `hcov` may have three non-missing levels if ‘h3’ appears in a model formula. Note that h2 cannot be combined with h3; h3 is for advanced use only and has not been fully tested.
The number of fitted parameters is the same as the corresponding finite mixture model if mixture terms ('h2', 'h3') appear in the model formulae. Otherwise (no mixture terms) estimating pmix requires a single extra parameter. The estimate of pmix then depends solely on the observed class proportions in the covariate, and the beta variance-covariance matrix will show zero covariance of pmix with other detection parameters.

**Models for pmix**

Variation in the parameter pmix may be modelled across sessions i.e., models such as pmix ~ session or pmix ~ Session are valid, as are formulae involving session covariates defined in the sessioncov argument of secr.fit.

If no mixture term appears in the formula for pmix then one is added automatically (usually 'h2'). This serves mostly to keep track of values in the output.

Attempting to model pmix as a function of individual covariates or other within-session terms (t, b etc.) will cause an error.

**Interpreting output**

When you display a fitted secr model the parameter estimates are in a final section headed ‘Fitted (real) parameters evaluated at base levels of covariates’. The same output may be obtained by calling the `predict` method directly. Calling `predict` has the advantage that you can obtain estimates for levels of the covariates other than the base levels, by specifying `newdata`. An example below shows how to specify h2 in `newdata`. [Note: `predict` is generic, and you must consult `?predict.secr` to see the help for the specific implementation of this method for fitted secr objects].

The output from `predict.secr` for a mixture model is a list with one component for each (possibly latent) class. Each row corresponds to a fitted real parameter: ordinarily these include the detection parameters (e.g., g0, sigma) and the mixing proportion (pmix).

In the case of a model fitted by maximizing the full likelihood (`CL = FALSE`), density D will also appear in the output. Note that only one parameter for density is estimated, the total density across classes. This total density figure appears twice in the output, once for each class.

The standard error (SE.estimate) is shown for each parameter. These are asymptotic estimates back-transformed from the link scale. The confidence limits are also back-transformed from the link scale (95% CI by default; vary `alpha` in `predict.secr` if you want e.g. 90% CI).

The mixing proportion pmix depends on the composition of the sample with respect to `hcov` and the detection model. For a null detection model the mixing proportion is exactly the proportion in the sample, with appropriate binomial confidence limits. Otherwise, the mixing proportion adjusts for class differences in the probability and scale of detection (see Examples).

The preceding refers to the default behaviour when pmix ~ h2. It is possible also to fix the mixing proportion at any arbitrary value (e.g., fixed = list(pmix = 0.5) for 1:1 sex ratio).

On output the classes are tagged with the factor levels of `hcov`, regardless of how few or how many individuals were actually of known class. If only a small fraction were of known class, and there is cryptic variation unrelated to `hcov`, then the association between the fitted classes and the nominal classes (i.e. levels of `hcov`) may be weak, and should not be trusted.
Limitations

Hybrid mixture models are incompatible with groups as presently implemented. The hcov likelihood conditions on the number of known-class individuals. A model fitted with hcov = NULL or with a different hcov covariate has in effect a different data set, and likelihoods, deviances or AICs cannot be compared. AIC can be used to compare models provided they all have the same hcov covariate in the call to secr.fit, whether or not h2 appears in the model definition.

Likelihood

The likelihood of the hybrid mixture model is detailed in an appendix of the vignette secr-finitemixtures.pdf.

homerange

Some ad hoc measures of home range size may be calculated in secr from capture–recapture data:
dbar is the mean distance between consecutive capture locations, pooled over individuals (e.g. Efford 2004).
moves returns the raw distances.
MMDM (for ‘Mean Maximum Distance Moved’) is the average maximum distance between detections of each individual i.e. the observed range length averaged over individuals (Otis et al. 1978).
ARL (or ‘Asymptotic Range Length’) is obtained by fitting an exponential curve to the scatter of observed individual range length vs the number of detections of each individual (Jett and Nichols 1987: 889).
RPSV (for ‘Root Pooled Spatial Variance’) is a measure of the 2-D dispersion of the locations at which individual animals are detected, pooled over individuals (cf Calhoun and Casby 1958, Slade and Swihart 1983).

moves reports the distance between successive detections of each animal.

centroids reports the averaged coordinates of each animal’s detections

ORL reports the observed range length of each animal, the maximum distance between any two detections.

trapsPerAnimal tabulates the number of animals recorded at 1, 2, ..., K detectors

Usage

dbar(capthist, userdist = NULL, mask = NULL)
MMDM(capthist, min.recapt = 1, full = FALSE, userdist = NULL, mask = NULL)
ARL(capthist, min.recapt = 1, plt = FALSE, full = FALSE, userdist = NULL, mask = NULL)
moves(capthist, userdist = NULL, full = FALSE, mask = NULL, names = FALSE)
RPSV(capthist, CC = FALSE)
ORL(capthist, userdist = NULL, mask = NULL)
centroids(capthist)
trapsPerAnimal(capthist)

Arguments

capthist object of class capthist
userdist function or matrix with user-defined distances
mask habitat mask passed to userdist function, if required
names logical; should results be ordered alphanumerically by row names?
min.recapt integer minimum number of recaptures for a detection history to be used
plt logical; if TRUE observed range length is plotted against number of recaptures
full logical; set to TRUE for detailed output
CC logical for whether to use Calhoun and Casby formula

Details

dbar is defined as –

\[
\overline{d} = \frac{\sum_{i=1}^{n} \sum_{j=1}^{n_i-1} \sqrt{(x_{i,j} - x_{i,j+1})^2 + (y_{i,j} - y_{i,j+1})^2}}{\sum_{i=1}^{n} (n_i - 1)}
\]

When CC = FALSE, RPSV is defined as –

\[
RPSV = \sqrt{\frac{\sum_{i=1}^{n} \sum_{j=1}^{n_i} [(x_{i,j} - \overline{x}_i)^2 + (y_{i,j} - \overline{y}_i)^2]}{\sum_{i=1}^{n} (n_i - 1) - 1}}
\]
Otherwise (CC = TRUE), RPSV uses the formula of Calhoun and Casby (1958) with a different denominator:

\[
s = \sqrt{\frac{\sum_{i=1}^{n} \sum_{j=1}^{n_i} [(x_{i,j} - \bar{x}_i)^2 + (y_{i,j} - \bar{y}_i)^2]}{2 \sum_{i=1}^{n} (n_i - 1)}}
\]

The Calhoun and Casby formula (offered from 2.9.1) correctly estimates $\sigma$ when trapping is on an infinite, fine grid, and is preferred for this reason. The original RPSV (CC = FALSE) is retained as the default for compatibility with previous versions of \texttt{secr}.

RPSV has a specific role as a proxy for detection scale in inverse-prediction estimation of density (Efford 2004, 2023).

RPSV is used in \texttt{autoini} to obtain plausible starting values for maximum likelihood estimation. \texttt{MMDM} and \texttt{ARL} discard data from detection histories containing fewer than $\min \text{. recapt} + 1$ detections.

The \texttt{userdist} option is included for exotic non-Euclidean cases (see e.g. \texttt{secr.fit} details). RPSV is not defined for non-Euclidean distances.

If \texttt{capthist} comprises standalone telemetry data (all detector ‘telemetry’) then calculations are performed on the telemetry coordinates.

Movements are reliably reported by \texttt{moves} only if there is a maximum of one detection per animal per occasion. The sequence of detections within any occasion is not known; where these occur the sequence used by \texttt{moves} is arbitrary (sequence follows detector index).

\section*{Value}

For \texttt{dbar}, \texttt{MMDM}, \texttt{ARL} and \texttt{RPSV} –

Scalar distance in metres, or a list of such values if \texttt{capthist} is a multi-session list.

The full argument may be used with \texttt{MMDM} and \texttt{ARL} to return more extensive output, particularly the observed range length for each detection history.

For \texttt{moves} –

List with one component for each animal, a vector of distances, or numeric(0) if the animal is detected only once. A list of such lists if \texttt{capthist} is a multi-session list.

For \texttt{centroids} –

For a single-session \texttt{capthist}, a matrix of two columns, the x- and y-coordinates of the centroid of the detections of each animal. The number of detections is returned as the attribute ‘Ndetections’, a 1-column matrix.

For a multi-session \texttt{capthist}, a 3-D array as before, but with a third dimension for the session. Centroid coordinates are missing (NA) if the animal was not detected in a session. The attribute ‘Ndetections’ with the number of detections per animal and session is a matrix.

For \texttt{trapsPerAnimal} –

A vector with the number of animals detected at k detectors.
Note

All measures are affected by the arrangement of detectors. dbar is also affected quite strongly by serial correlation in the sampled locations. Using dbar with ‘proximity’ detectors raises a problem of interpretation, as the original sequence of multiple detections within an occasion is unknown. RPSV is a value analogous to the standard deviation of locations about the home range centre.

The value returned by dbar for ‘proximity’ or ‘count’ detectors is of little use because multiple detections of an individual within an occasion are in arbitrary order.

Inclusion of these measures in the secr package does not mean they are recommended for general use! It is usually better to use a spatial parameter from a fitted model (e.g., \( \sigma \) of the half-normal detection function). Even then, be careful that \( \sigma \) is not ‘contaminated’ with behavioural effects (e.g. attraction of animal to detector) or ‘detection at a distance’.

The argument ‘names’ was added in 3.0.1. The default names = FALSE causes a change in behaviour from that version onwards.

Flat-tailed Horned Lizard Dataset

Description

Data from multiple searches for flat-tailed horned lizards (*Phrynosoma mcalli*) on a plot in Arizona, USA.

Usage

hornedlizardCH

Details

The flat-tailed horned lizard (*Phrynosoma mcalli*) is a desert lizard found in parts of southwestern Arizona, southeastern California and northern Mexico. There is considerable concern about its conservation status. The species is cryptically coloured and has the habit of burying under the sand when approached, making it difficult or impossible to obtain a complete count (Grant and Doherty 2007).

K. V. Young conducted a capture–recapture survey of flat-tailed horned lizards 25 km south of Yuma, Arizona, in the Sonoran Desert. The habitat was loose sand dominated by creosote bush and occasional bur-sage and Galletta grass. A 9-ha plot was surveyed 14 times over 17 days (14 June to 1 July 2005). On each occasion the entire 300 m x 300 m plot was searched for lizards. Locations within the plot were recorded by handheld GPS. Lizards were captured by hand and marked individually on their underside with a permanent marker. Marks are lost when the lizard sheds, but this happens infrequently and probably caused few or no identification errors during the 2.5-week study.

A total of 68 individuals were captured 134 times. Exactly half of the individuals were recaptured at least once.

Royle and Young (2008) analysed the present dataset to demonstrate a method for density estimation using data augmentation and MCMC simulation. They noted that the plot size was much larger than has been suggested as being practical in operational monitoring efforts for this species, that the plot was chosen specifically because a high density of individuals was present, and that high densities typically correspond to less movement in this species. The state space in their analysis was a square comprising the searched area and a 100-m buffer (J. A. Royle pers. comm.).

The detector type for these data is ‘polygonX’ and there is a single detector (the square plot). The data comprise a capture history matrix (the body of hornedlizardCH) and the x-y coordinates of each positive detection (stored as an attribute that may be displayed with the ‘xy’ function); the ‘traps’ attribute of hornedlizardCH contains the vertices of the plot. See secr-datainput.pdf for guidance on data input.

Non-zero entries in a polygonX capture-history matrix indicate the number of the polygon containing the detection. In this case there was just one polygon, so entries are 0 or 1. No animal can appear more than once per occasion with the polygonX detector type, so there is no need to specify ‘binomN = 1’ in secr.fit.

Description

Data of H. N. Coulombe from live trapping of feral house mice (Mus musculus) in a salt marsh, California, USA.

Usage

housemouse

Details

H. N. Coulombe conducted a live-trapping study on an outbreak of feral house mice in a salt marsh in mid-December 1962 at Ballana Creek, Los Angeles County, California. A square 10 x 10 grid was used with 100 Sherman traps spaced 3 m apart. Trapping was done twice daily, morning and evening, for 5 days.

The dataset was described by Otis et al. (1978) and distributed with their CAPTURE software (now available from [https://www.mbr-pwrc.usgs.gov/software.html](https://www.mbr-pwrc.usgs.gov/software.html)). Otis et al. (1978 p. 62, 68) cite Coulombe’s unpublished 1965 master’s thesis from the University of California, Los Angeles, California.

The data are provided as a single-session capthist object. There are two individual covariates: sex (factor levels ‘f’, ‘m’) and age class (factor levels ‘j’, ‘sa’, ‘a’). The sex of two animals is not available (NA); it is necessary to drop these records for analyses using ‘sex’ unless missing values are specifically allowed, as in hcov.

The datasets were originally in the CAPTURE ‘xy complete’ format which for each detection gives the ‘column’ and ‘row’ numbers of the trap (e.g. ‘9 5’ for a capture in the trap at position (x=9, y=5) on the grid). Trap identifiers have been recoded as strings with no spaces by inserting zeros (e.g. ‘0905’ in this example).

Sherman traps are designed to capture one animal at a time, but the data include 30 double captures and one occasion when there were 4 individuals in a trap at one time. The true detector type therefore falls between ‘single’ and ‘multi’. Detector type is set to ‘multi’ in the distributed data objects.

Otis et al. (1978) report various analyses including a closure test on the full data, and model selection and density estimation on data from the mornings only.

Source

File ‘examples’ distributed with program CAPTURE.

Examples

```r
plot(housemouse, title = paste("Coulombe (1965), Mus musculus,",
    "California salt marsh"), border = 5, rad = 0.5,
    gridlines = FALSE)

morning <- subset(housemouse, occ = c(1,3,5,7,9))
summary(morning)

## drop 2 unknown-sex mice
known.sex <- subset(housemouse, !is.na(covariates(housemouse)$sex))

## reveal multiple captures
table(trap(housemouse), occasion(housemouse))

## Not run:
## assess need to distinguish morning and afternoon samples
housemouse.0 <- secr.fit (housemouse, buffer = 20)
housemouse.ampm <- secr.fit (housemouse, model = g0~tcov, buffer = 20,
    timecov = c(0,1,0,1,0,1,0,1,0,1))
AIC(housemouse.0, housemouse.ampm)

## End(Not run)
```

Internal Functions

**Description**

Various functions called internally by `secr` and not exported.

**Usage**

```r
boundarytoSF (poly)
Dfn2(designD, beta = NULL, ...)
```
Arguments

poly  data to define one or more polygons
designD  dataframe of density design data (output from D.designdata)
beta  numeric vector of beta values (see Details for NULL)
...  other arguments (not used)

Details

The function boundarytoSF converts various possible polygon input formats to a standard form (sfc).

Possible inputs are:

<table>
<thead>
<tr>
<th>Input</th>
<th>From</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>2-column matrix or dataframe</td>
<td>base R</td>
<td>Note</td>
</tr>
<tr>
<td>SpatialPolygons</td>
<td>sp</td>
<td>geometry type POLYGON or MULTIPOLYGON</td>
</tr>
<tr>
<td>SpatialPolygonsDataFrame</td>
<td>sp</td>
<td>geometry type POLYGON or MULTIPOLYGON</td>
</tr>
<tr>
<td>SpatVector</td>
<td>terra</td>
<td>geometry type POLYGON or MULTIPOLYGON</td>
</tr>
<tr>
<td>sf</td>
<td>sf</td>
<td>geometry type POLYGON or MULTIPOLYGON</td>
</tr>
<tr>
<td>sfc</td>
<td>sf</td>
<td>geometry type POLYGON or MULTIPOLYGON</td>
</tr>
</tbody>
</table>

Matrix input defines a single polygon.

Dfn2 is supplied automatically as ‘details’ argument Dfn in secr.fit when the switch Dlambda is set to TRUE for the multi-session trend reparameterization of density. Dfn2 uses beta = NULL to return the required number of density coefficients (beta parameters) in the model.

Value

boundarytoSF – Spatial object of sf class sfc, containing a geometry set of type POLYGON or MULTIPOLYGON. NULL input results in NULL output.

Dfn2 – Vector of density values on the link scale, suitable for the internal array (mask x groups x sessions).

## End(Not run)
```

Description

Functions for data manipulation

Usage

```r
intervals(object, ...) 
intervals(object) <- value 
sessionlabels(object, ...) 
sessionlabels(object) <- value 
```

Arguments

- `object`: capthist object
- `value`: vector of intervals or primary session labels
- `...`: other arguments (not used)

Details

`intervals` extracts the ‘interval’ attribute if it exists.

The attribute ‘intervals’ is set automatically by the secr function `join`.

`sessionlabels` provides session names for the primary sessions encoded in a “single-session” capthist object (e.g., the result of `join`) that has an intervals attribute. The names are used by some summary functions in the package `openCR` (M. Efford unpubl.) (`m.array`, `JS.counts`).

The function `session` has a different purpose: labelling sessions in a multi-session capthist object. However, session names of multi-session input are used automatically by `join` to construct the `sessionlabels` attribute of the resulting single-session object.
Value

For intervals, a numeric vector of time intervals, one less than the number of occasions (secondary sessions).

For sessionlabels, a character vector of primary session names.

Note

There is a naming conflict with the intervals function in nlme.

Examples

singlesessionCH <- join(ovenCH)
intervals(singlesessionCH)
sessionlabels(singlesessionCH)

join
Combine or Split Sessions of capthist Object

Description

Make a single-session capthist object from a list of single-session objects, or a multi-session capthist object.

Usage

join(object, remove.dupl.sites = TRUE, tol = 0.001, sites.by.name = FALSE, drop.sites = FALSE, intervals = NULL, sessionlabels = NULL, timevaryingcov = NULL)
unjoin(object, intervals, ...)

Arguments

object list of single-session objects, or a multi-session capthist object [join], or a single-session capthist object [unjoin]
remove.dupl.sites logical; if TRUE then a single record is retained for each trap site used in multiple input sessions
tol absolute distance in metres within which sites are considered identical
sites.by.name logical; if TRUE and remove.dupl.sites then duplicate sites are inferred from row names rather than x-y coordinates
join

drop.sites logical; if TRUE then site information is discarded
intervals vector of times between sessions (join) or occasions (unjoin; zero indicates same session)
sessionlabels vector of session names
timevaryingcov character vector of covariate names
... other arguments passed to subset.capthist

Details

join The input sessions are assumed to be of the same detector type and to have the same attributes (e.g., covariates should be present for all or none).
The number of occasions (columns) in the output is equal to the sum of the number of occasions in each input.
Duplicates may be defined either as sites within a given distance (tol) or sites with the same name (sites.by.name = TRUE). Using site names is faster.
For non-spatial analyses it is efficient to drop the third dimension and discard the traps attribute (drop.sites = TRUE).
A new dataframe of individual covariates is formed using the covariates for the first occurrence of each animal.
If timevaryingcov is given then for each name a new covariate is generated for each session and populated with values observed in that session, or NA if the animal was not detected. A ‘timevaryingcov’ (list) attribute is created that associates each set of new session-specific columns with the corresponding old name, so that it may be used in formulae (see timevaryingcov).
Attributes xy and signal are handled appropriately, as is trap usage.

unjoin The input grouping of occasions (columns) into sessions is specified via intervals. This is a vector of length one less than the number of occasions (columns) in object. Elements greater than zero indicate a new session.
The intervals argument may be omitted if object has a valid ‘intervals’ attribute, as in the output from join.

Value

For join, a single-session capthist object. The vector attribute ‘intervals’ records the distinction between occasions that are adjacent in the input (interval = 0) and those that are in consecutive sessions (e.g., interval = 1); ‘intervals’ has length one less than the number of occasions.
For unjoin, a multi-session capthist object. Sessions are named with integers.

Note

Do not confuse unjoin with split.capthist which splits by row (animal) rather than by column (occasion).
Occasions survive intact; to pool occasions use reduce.capthist.
join was modified in version 2.9.5 to check whether the components of ‘object’ all used the same detectors (‘traps’) (putting aside differences in usage). If the traps are identical and remove.dupl.sites = TRUE then the resulting ‘capthist’ uses the common list of detectors, with a
usage attribute formed by concatenating the usage columns of the input. This is faster than the previous filtering algorithm using 'tol'; the older algorithm is still used if the traps differ. Problems may be encountered with large datasets. These may be alleviated by setting sites.by.name = TRUE (if matching sites have matching names, avoiding the need for coordinate matching) or drop.sites = TRUE (if only non-spatial data are required for openCR).

kfn

**Overlap Index**

Description

Computes the overlap index of Efford et al. (2016) from various inputs, including fitted models.

Usage

kfn(object)
Arguments

object fitted secr model, numeric vector, matrix, dataframe

Details

kfn simply computes \( k = \sigma \sqrt{D}/100 \), where \( \sigma \) is the sigma parameter of a fitted halfnormal detection function and \( D \) is the corresponding density estimate. The factor of \( 1/100 \) adjusts for the units used in secr (sigma in metres; \( D \) in animals per hectare).

Input may be in any of these forms

1. vector with \( D \) and \( \sigma \) in the first and second positions.
2. matrix with each row as in (1)
3. dataframe such as produced by predict.secr with rows ‘\( D \)’ and ‘sigma’, and column ‘estimate’.
4. fitted secr model
5. a list of any of the above

Value

Numeric vector with elements ‘\( D \)’, ‘\( \sigma \)’ and ‘\( k \)’, or a matrix with these columns.

Note

The index should not be taken too literally as a measure of overlap: it represents the overlap expected if activity centres are randomly distributed and if home ranges have bivariate normal utilisation. Thus it does not measure overlap due to social behaviour etc. except as that affects home range size.

The index may be estimated directly using the sigmak parameterization (i.e., when sigmak appears in the model for secr.fit). This provides SE and confidence limits for sigmak (= \( k \)). However, the directly estimated value of sigmak lacks the unit correction and is therefore \( 100 \times \) the value from kfn.

Examples

kfn(secr.demo.0)

## compare
## fitk <- secr.fit(captdata, model = sigmak~1, buffer = 100, trace = FALSE)
LLsurface

Description

LLsurface is a generic function to calculate log likelihood over a grid of values of two coefficients (beta parameters) from a fitted model and optionally make an approximate contour plot of the log likelihood surface.

A method is provided for secr objects.

Usage

LLsurface(object, ...)

## S3 method for class 'secr'
LLsurface(object, betapar = c("g0", "sigma"), xval = NULL, yval = NULL, centre = NULL, realscale = TRUE, plot = TRUE, plotfitted = TRUE, ncores = NULL, ...)

Arguments

- **object**: fitted model, secr object output from secr.fit
- **betapar**: character vector giving the names of two beta parameters
- **xval**: vector of numeric values for x-dimension of grid
- **yval**: vector of numeric values for y-dimension of grid
- **centre**: vector of central values for all beta parameters
- **realscale**: logical. If TRUE input and output of x and y is on the untransformed (inverse-link) scale.
- **plot**: logical. If TRUE a contour plot is produced
- **plotfitted**: logical. If TRUE the MLE from object is shown on the plot (+)
- **ncores**: integer number of threads for parallel processing
- **...**: other arguments passed to contour

Details

centre is set by default to the fitted values of the beta parameters in object. This has the effect of holding parameters other than those in betapar at their fitted values.

If xval or yval is not provided then 11 values are set at equal spacing between 0.8 and 1.2 times the values in centre (on the ‘real’ scale if realscale = TRUE and on the ‘beta’ scale otherwise).

Contour plots may be customized by passing graphical parameters through the ... argument.

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).
logit

Value

A matrix of the log likelihood evaluated at each grid point (rows x, columns y), invisibly if plot = TRUE. Failed evaluations return NA.

Note

LLsurface works for named ‘beta’ parameters rather than ‘real’ parameters. The default realscale = TRUE only works for beta parameters that share the name of the real parameter to which they relate i.e. the beta parameter for the base level of the real parameter. This is because link functions are defined for real parameters not beta parameters.

The contours are approximate because they rely on interpolation. See Examples for a more reliable way to compare the likelihood at the MLE with nearby points on the surface.

Examples

```r
## Not run:
LLsurface(secrdemo.CL, xval = seq(0.16,0.40,0.02),
          yval = 25:35, nlevels = 20)
## now verify MLE
## click on MLE and apparent 'peak'
if (interactive()) {
  xy <- locator(2)
  LLsurface(secrdemo.CL, xval = xy$x, yval = xy$y, plot = FALSE)
}
## End(Not run)
```

logit

Logit Transformation

Description

Transform real values to the logit scale, and the inverse.

Usage

```r
logit(x)
invlogit(y)
```

Arguments

```r
x  vector of numeric values in (0,1) (possibly a probability)
y  vector of numeric values
```
The logit transformation is defined as \( \text{logit}(x) = \log\left(\frac{x}{1-x}\right) \) for \( x \in (0,1) \).

**Value**

Numeric value on requested scale.

**Note**

\( \text{logit} \) is equivalent to \( \text{qlogis} \), and \( \text{invlogit} \) is equivalent to \( \text{plogis} \) (both R functions in the \text{stats} package). \( \text{logit} \) and \( \text{invlogit} \) are used in \text{secr} because they are slightly more robust to bad input, and their names are more memorable!

**Examples**

\[
\begin{align*}
\text{logit}(0.5) \\
\text{invlogit}(\text{logit}(0.2))
\end{align*}
\]

---

**logmultinom**

*Multinomial Coefficient of SECR Likelihood*

**Description**

Compute the constant multinomial component of the SECR log likelihood

**Usage**

\[
\text{logmultinom}(\text{capthist}, \text{grp} = \text{NULL})
\]

**Arguments**

- `capthist` *capthist object*
- `grp` *factor defining group membership, or a list (see Details)*

**Details**

For a particular dataset and grouping, the multinomial coefficient is a constant; it does not depend on the parameters and may be ignored when maximizing the likelihood to obtain parameter estimates. Nevertheless, the log likelihood reported by \text{secr.fit} includes this component *unless* the detector type is ‘signal’, ‘polygon’, ‘polygonX’, ‘transect’ or ‘transectX’ (from 2.0.0).

If \( \text{grp} \) is \text{NULL} then all animals are assumed to belong to one group. Otherwise, the length of \( \text{grp} \) should equal the number of rows of \( \text{capthist} \).

\( \text{grp} \) may also be any vector that can be coerced to a factor. If \( \text{capthist} \) is a multi-session \( \text{capthist} \) object then \( \text{grp} \) should be a list with one factor per session.
If capture histories are not assigned to groups the value is the logarithm of

\[
\binom{n}{n_1, \ldots, n_C} = \frac{n!}{n_1! n_2! \cdots n_C!}
\]

where \( n \) is the total number of capture histories and \( n_1 \ldots n_C \) are the frequencies with which each of the \( C \) unique capture histories were observed.

If capture histories are assigned to \( G \) groups the value is the logarithm of

\[
\prod_{g=1}^{G} \frac{n_g!}{n_{g1}! n_{g2}! \cdots n_{gC_g}!}
\]

where \( n_g \) is the number of capture histories of group \( g \) and \( n_{g1} \ldots n_{gC_g} \) are the frequencies with which each of the \( C_g \) unique capture histories were observed for group \( g \).

For multi-session data, the value is the sum of the single-session values. Both session structure and group structure therefore affect the value computed. Users will seldom need this function.

**Value**

The numeric value of the log likelihood component.

**References**

**See Also**

*stoatDNA*

**Examples**

```r
## no groups
logmultinom(stoatCH)
```
LR.test  

**Likelihood Ratio Test**

**Description**

Compute likelihood ratio test to compare two fitted models, one nested within the other.

**Usage**

```r
LR.test(model1, model2)
```

**Arguments**

- `model1` fitted model
- `model2` fitted model

**Details**

The fitted models must be of a class for which there is a `logLik` method (e.g., ‘secr’ or ‘lm’). Check with `methods("logLik")`.

The models must be nested (no check is performed - this is up to the user), but either `model1` or `model2` may be the more general model.

The models must also be compatible by the criteria of `AICcompatible`.

The test statistic is twice the difference of the maximized likelihoods. It is compared to a chi-square distribution with df equal to the number of extra parameters in the more complex model.

**Value**

Object of class ‘htest’, a list with components

- `statistic` value the test statistic
- `parameter` degrees of freedom of the approximate chi-squared distribution of the test statistic
- `p.value` probability of test statistic assuming chi-square distribution
- `method` character string indicating the type of test performed
- `data.name` character string with names of models compared

**See Also**

`AICcompatible, AIC.secr, score.test`

**Examples**

```r
## two pre-fitted models
AIC (secrdemo.0, secrdemo.b)
LR.test (secrdemo.0, secrdemo.b)
```
**make.capthist**

*Construct capthist Object*

**Description**

Form a capthist object from a data frame of capture records and a traps object.

**Usage**

```r
make.capthist(captures, traps, fmt = c("trapID", "XY"), nooccasions = NULL,
              covnames = NULL, bysession = TRUE, sortrows = TRUE,
              cutval = NULL, tol = 0.01, snapXY = FALSE, noncapt = "NONE", signalcovariates)
```

**Arguments**

- `captures`: dataframe of capture records in one of two possible formats (see Details)
- `traps`: object of class `traps` describing an array of passive detectors
- `fmt`: character string for capture format.
- `nooccasions`: number of occasions on which detectors were operated
- `covnames`: character vector of names for individual covariate fields
- `bysession`: logical, if true then ID are made unique by session
- `sortrows`: logical, if true then rows are sorted in ascending order of animalID
- `cutval`: numeric, threshold of signal strength for ‘signal’ detector type
- `tol`: numeric, snap tolerance in metres
- `snapXY`: logical; if TRUE then fmt = ‘XY’ uses nearest trap within tol for non-polygon detectors
- `noncapt`: character value; animal ID used for ‘no captures’
- `signalcovariates`: character vector of field names from ‘captures’

**Details**

`make.capthist` is the most flexible way to prepare data for `secr.fit`. See `read.capthist` for a more streamlined way to read data from text files for common detector types. Each row of the input data frame `captures` represents a detection on one occasion. The capture data frame may be formed from a text file with `read.table`.

Input formats are based on the Density software (Efford 2012; see also `secr-datainput.pdf`). If `fmt` = "XY" the required fields are (session, ID, occasion, x, y) in that order. If `fmt` = "trapID" the required fields are (session, ID, occasion, trap), where trap is the numeric index of the relevant detector in `traps`. session and ID may be character-, vector- or factor-valued; other required fields are numeric. Fields are matched by position (column number), not by name. Columns after the required fields are interpreted as individual covariates that may be continuous (e.g., size) or categorical (e.g., age, sex).
If captures has data from multiple sessions then traps may be either a list of traps objects, one per session, or a single traps object that is assumed to apply throughout. Similarly, noccasions may be a vector specifying the number of occasions in each session.

Covariates are assumed constant for each individual; the first non-missing value is used. The length of covnames should equal the number of covariate fields in captures.

bysession takes effect when the same individual is detected in two or more sessions: TRUE results in one capture history per session, FALSE has the effect of generating a single capture history (this is not appropriate for the models currently provided in secr).

Deaths are coded as negative values in the occasion field of captures. Occasions should be numbered 1, 2, ..., noccasions. By default, the number of occasions is the maximum value of 'occasion' in captures.

Signal strengths may be provided in the fifth (fmt = trapID) or sixth (fmt = XY) columns. Detections with signal strength missing (NA) or below 'cutval' are discarded.

A session may result in no detections. In this case a null line is included in captures using the animal ID field given by noncapt, the maximum occasion number, and any trapID (e.g. "sess1 NONE 5 1" for a 5-occasion session) (or equivalently "sess1 NONE 5 10 10" for fmt = XY).

Nonspatial data (Session, AnimalID, Occasion and possibly individual covariates) may be entered by omitting the ‘traps’ argument or setting it to NULL.

Value

An object of class capthist (a matrix or array of detection data with attributes for detector positions etc.). For ‘single’ and ‘multi’ detectors this is a matrix with one row per animal and one column per occasion (dim(capthist)=c(nc,noccasions)); each element is either zero (no detection) or a detector number (the row number in traps not the row name). For ‘proximity’ detectors capthist is an array of values {-1, 0, 1} and dim(capthist)=c(nc,noccasions,ntraps). The number of animals nc is determined from the input, as is noccasions if it is not specified. traps, covariates and other data are retained as attributes of capthist.

Deaths during the experiment are represented as negative values in capthist.

For ‘signal’ and ‘signalnoise’ detectors, the columns of captures identified in signalcovariates are saved along with signal strength measurements in the attribute ‘signalframe’.

If the input has data from multiple sessions then the output is an object of class c("capthist", "list") comprising a list of single-session capthist objects.

Note

make.capthist requires that the data for captures and traps already exist as R objects. To read data from external (text) files, first use read.table and read.traps, or try read.capthist for a one-step solution.

Prior to secr 4.4.0, occasional valid records for "multi" and "single" detectors were rejected as duplicates.

From secr 4.5.0, ‘snapXY’ works for transects as well as point detectors.
A lacework design comprises a square grid with detectors placed at regular distances along the grid lines (Efford unpubl.). This requires fewer detectors than uniform coverage at close spacing and is simpler than clustered designs, while providing good spatial coverage and protection from alignment bias (Efford 2019).

Usage

```r
make.lacework(region, spacing = c(100, 20), times = NULL, origin = NULL, rotate = 0, radius = NULL, detector = "multi", keep.design = TRUE)
```
Arguments

region dataframe or SpatialPolygonsDataFrame with coordinates of perimeter
spacing numeric 2-vector with major (grid) and minor spacings, or minor spacing only
times numeric ratio major:minor spacing if spacing length 1
origin numeric vector giving x- and y-coordinates of fixed grid origin (origin is otherwise random)
rotate numeric; number of degrees by which to rotate design clockwise about centroid of region bounding box
radius numeric; detectors are dropped if they are further than this from a crossing
detector character detector type – see `make.grid`
keep.design logical; if TRUE then input argument values are retained

Details

It is tidy for the major spacing (spacing[1]) to be a multiple of the minor spacing (spacing[2]); precisely one detector is then placed at each grid intersection. This outcome may also be achieved by providing only the minor spacing in the spacing argument and specifying an integer value for times.

In general it is better not to specify origin. Specifying both origin and rotate may result in incomplete coverage, as the desired grid is relative to the bounding box of the rotated region.

Set `radius < spacing[1]/2` to break lacework into multiple cross-shaped arrays centred on the intersections (crossing points) and truncated at `radius` metres (assuming you follow advice and express all linear measurements in metres).

The number of detectors should not exceed 5000.

Value

An `secr` traps object. The attribute ‘crossings’ is a 2-column matrix with the coordinates of the intersection points. If `keep.design` is TRUE then the input argument values are retained in attribute ‘design’ (a list with first component function = ‘make.lacework’).

`make.systematic`

Examples

```r
tbps <- make.lacework(possumarea, c(1000,100), rotate = 45, detector = 'proximity')
plot(tbps, gridspace = 1000)
lines(possumarea)
```
Description

Construct a habitat mask object for spatially explicit capture-recapture. A mask object is a set of points with optional attributes.

Usage

```r
c(make.mask(traps, buffer = 100, spacing = NULL, nx = 64, ny = 64, type =
    c("traprect", "trapbuffer", "pdot", "polygon", "clusterrect",
    "clusterbuffer", "rectangular", "polybuffer"), poly = NULL, poly.habitat = TRUE,
    cell.overlap = c("centre", "any", "all"), keep.poly = TRUE, check.poly = TRUE,
    pdotmin = 0.001, random.origin = FALSE,
    ...))
```

Arguments

- `traps` object of class `traps`
- `buffer` width of buffer in metres
- `spacing` spacing between grid points (metres)
- `nx` number of grid points in ‘x’ direction
- `ny` number of grid points in ‘y’ direction (type = ‘rectangular’)
- `type` character string for method
- `poly` bounding polygon to which mask should be clipped (see Details)
- `poly.habitat` logical for whether poly represents habitat or its inverse (non-habitat)
- `cell.overlap` character string for cell vertices used to determine overlap with ‘poly’
- `keep.poly` logical; if TRUE any bounding polygon is saved as the attribute ‘polygon’
- `check.poly` logical; if TRUE a warning is given for traps that lie outside a bounding polygon
- `pdotmin` minimum detection probability for inclusion in mask when `type = "pdot"` (optional)
- `random.origin` logical; if TRUE the mask coordinates are jittered
- `...` additional arguments passed to `pdot` when `type = "pdot"`
Details

The `traprect` method constructs a grid of points in the rectangle formed by adding a buffer strip to the minimum and maximum x-y coordinates of the detectors in `traps`. Both `trapbuffer` and `pdot` start with a `traprect` mask and drop some points.

The `trapbuffer` method restricts the grid to points within distance `buffer` of any detector.

The `pdot` method restricts the grid to points for which the net detection probability $p.(X)$ (see `pdot`) is at least `pdotmin`. Additional parameters are used by `pdot` (detectpar, noccasions). Set these with the ... argument; otherwise `make.mask` will silently use the arbitrary defaults. `pdot` is currently limited to a halfnormal detection function.

The `clusterrect` method constructs a grid of rectangular submasks centred on 'clusters' of detectors generated with `trap.builder` (possibly indirectly by `make.systematic`). The `clusterbuffer` method resembles 'trapbuffer', but is usually faster when traps are arranged in clusters because it starts with a 'clusterrect' mask.

The `rectangular` method constructs a simple rectangular mask with the given nx, ny and spacing.

The `polybuffer` method constructs a mask by buffering around the polygon specified in the `poly` argument. If that inherits from 'SpatialPolygons' or 'sfc' then the buffering is performed with `st_buffer`. Otherwise, buffering is approximate, based on the distance to points on an initial discretized mask enclosed by `poly` (points at half the current 'spacing').

If `poly` is specified, points outside `poly` are dropped (unless type = "polybuffer"). The default is to require only the centre to lie within `poly`; use `cell.overlap = "all"` to require all cell corners to lie within `poly`, or `cell.overlap = "any"` to accept cells with any corner in `poly`. The 'polygon' method places points on a rectangular grid clipped to the polygon (buffer is not used). Thus 'traprect' is equivalent to 'polygon' when `poly` is supplied. `poly` may be either

- a matrix or dataframe of two columns interpreted as x and y coordinates, or
- an object from package 'sf' with polygon geometries, or
- a SpatialPolygons or SpatialPolygonsDataFrame object as defined in the package 'sp', possibly imported by reading a shapefile.

If `spacing` is not specified then it is determined by dividing the range of the x coordinates (including any buffer) by `nx`.

`random.origin` shifts the origin of the mask by a uniform random displacement within a spacing x spacing grid cell, while ensuring that the mask also satisfies the buffer requirement. `random.origin` is available only for 'traprect', 'trapbuffer', 'polygon', and 'rectangular' types, and spacing must be specified.

Value

An object of class `mask`. When `keep.poly = TRUE`, `poly` and `poly.habitat` are saved as attributes of the mask.

Note

A warning is displayed if `type = "pdot"` and the buffer is too small to include all points with $p. > pdotmin$. 
A habitat mask is needed to fit an SECR model and for some related computations. The default mask settings in secr.fit may be good enough, but it is preferable to use make.mask to construct a mask in advance and to pass that mask as an argument to secr.fit.

The function buffer.contour displays the extent of one or more ‘trapbuffer’ zones - i.e. the effect of buffering the detector array with varying strip widths.

plot(tempmask)
plot(temptrap, add = TRUE)

## Not run:
## form mask by "pdot" method
temptrap <- make.grid(nx = 6, ny = 6)
tempmask <- make.mask(temptrap, buffer = 150, type = "pdot",
                    pdotmin = 0.0001, detectpar = list(g0 = 0.1, sigma = 30),
                    nooccasions = 4)
plot(tempmask)
plot(temptrap, add = TRUE)

## Using an ESRI polygon shapefile for clipping (shapefile
## polygons may include multiple islands and holes).

library(sf)
shpfilename <- system.file("extdata/possumarea.shp", package = "secr")
possumarea <- st_read(shpfilename)

possummask2 <- make.mask(traps(possumCH), spacing = 20,
                         buffer = 250, type = "trapbuffer", poly = possumarea)
par(mar = c(1,6,6,6), xpd = TRUE)
plot(possummask2, ppo = TRUE)
plot(traps(possumCH), add = TRUE)
par(mar = c(5,4,4,2) + 0.1, xpd = FALSE)

## if the polygon delineates non-habitat ...
```r
seaPossumMask <- make.mask(traps(possumCH), buffer = 1000,
  type = "traprect", poly = possumarea, poly.habitat = FALSE)
plot(seaPossumMask)
plot(traps(possumCH), add = TRUE)
## this mask is not useful!
```

## End(Not run)

---

**make.systematic**

Construct Systematic Detector Design

**Description**

A rectangular grid of clusters within a polygonal region.

**Usage**

```r
make.systematic(n, cluster, region, spacing = NULL, origin = NULL,
  originoffset = c(0, 0), chequerboard = c('all', 'black', 'white'),
  order = c('x', 'y', 'xb', 'yb'), rotate = 0, centrexy = NULL,
  keep.design = TRUE, ...)
```

**Arguments**

- `n`: integer approximate number of clusters (see Details)
- `cluster`: traps object defining a single cluster
- `region`: dataframe or SpatialPolygonsDataFrame with coordinates of perimeter
- `spacing`: scalar distance between cluster centres
- `origin`: vector giving x- and y-coordinates of fixed grid origin (origin is otherwise random)
- `originoffset`: numeric; 2-vector (x,y offsets); see Details
- `chequerboard`: logical; if not 'all' then alternate clusters are omitted
- `order`: character; sort order for clusters (see Details)
- `rotate`: numeric; number of degrees by which to rotate entire design clockwise about centroid of region bounding box
- `centrexy`: numeric; 2-vector for centre of rotation, if any
- `keep.design`: logical; if TRUE then input argument values are retained
- `...`: arguments passed to `trap.builder`
make.systematic

Details

region may be any shape.

region may be one of the spatial classes described in \texttt{boundarytoSF}. Otherwise, region should
be a dataframe with columns ‘x’ and ‘y’.

spacing may be a vector with separate values for spacing in x- and y- directions. If spacing is
provided then \( n \) is ignored.

If \( n \) is a scalar, the spacing of clusters is determined from the area of the bounding box of \( \text{region} \)
divided by the requested number of clusters (this does not necessarily result in exactly \( n \) clusters).

If \( n \) is a vector of two integers these are taken to be the number of columns and the number of rows.

After preparing a frame of cluster centres, \texttt{make.systematic} calls \texttt{trap.builder} with \texttt{method} =
‘all’; … allows the arguments ‘rotation’, ‘edgemethod’, ‘plt’, and ‘detector’ to be passed. Setting
the \texttt{trap.builder} arguments frame, method, and \texttt{samplefactor} has no effect.

Note the distinction between argument \texttt{rotate} and the \texttt{trap.builder} argument rotation that is
applied separately to each cluster.

If origin is not specified then a random uniform origin is chosen within a box (width = spacing)
placed with its bottom left corner at the bottom left of the bounding box of \( \text{region} \), shifted
by \texttt{originoffset}. Before version 3.1.8 the behaviour of \texttt{make.systematic} was equivalent to
\texttt{originoffset} = \( c(wx,wy) \) where \( wx,wy \) are the cluster half widths.

\texttt{chequerboard = "black"} retains black ‘squares’ and \texttt{chequerboard = "white"} retains white ‘squares’,
where the lower left cluster in the candidate rectangle of cluster origins is black, as on a chess board.
The effect is the same as increasing spacing by \( \sqrt{2} \) and rotating through 45 degrees.

\texttt{order} determines the ordering of clusters in the resulting \texttt{traps} object. The options are a subset of
those for \texttt{ID} argument of \texttt{make.grid}:

\begin{verbatim}
 Option  Sort order
 x       column-dominant
 y       row-dominant
 xb      column-dominant boustrophedonical (alternate columns reversed)
 yb      row-dominant boustrophedonical (alternate rows reversed)
\end{verbatim}

\texttt{rotate} rotates the array about the given centre (default is centroid of the bounding box of \texttt{region}).

Value

A single-session ‘traps’ object.

From 3.2.0 these additional attributes are set –

\begin{verbatim}
origin  coordinates of grid origin
centres coordinates of true cluster centres (cf \texttt{cluster.centres})
originbox vertices of rectangular spatial sampling frame for random origin
\end{verbatim}

From 4.2.0 if \texttt{keep.design} is \texttt{TRUE} then the input argument values are retained in attribute ‘design’
(a list with first component \texttt{function} = ‘make.systematic’).
Note

Do not confuse with the simpler function `make.grid`, which places single detectors in a rectangular array.

See Also

`trap.builder, make.lacework, cluster.centres`

Examples

```r
mini <- make.grid(nx = 2, ny = 2, spacing = 100)
region <- cbind(x=c(0,2000,2000,0), y=c(0,0,2000,2000))
temp <- make.systematic(25, mini, region, plt = TRUE)
temp <- make.systematic(c(6, 6), mini, region, plt = TRUE, rotation = -1)

## Example using shapefile "possumarea.shp" in
## "extdata" folder. By default, each cluster is
## a single multi-catch detector

## Not run:
library(sf)
shpfilename <- system.file("extdata/possumarea.shp", package = "secr")
possumarea <- st_read(shpfilename)

possumgrid <- make.systematic(spacing = 100, region =
possumarea, plt = TRUE)

## or with 2 x 2 clusters
possumgrid2 <- make.systematic(spacing = 300,
  cluster = make.grid(nx = 2, ny = 2, spacing = 100),
  region = possumarea, plt = TRUE, edgemethod =
  "allinside")

## label clusters
text(cluster.centres(possumgrid2), levels(clusterID
  (possumgrid2)), cex=0.7)

## If you have GPSBabel installed and on the Path
## then coordinates can be projected and uploaded
## to a GPS with `writeGPS`, which also requires the
## package `proj4`. Defaults are for a Garmin GPS
## connected by USB.

if (interactive()) {
  writeGPS(possumgrid, proj = "+proj=nzmg")
}

## End(Not run)
```
Description

Construct a rectangular array of detectors (trapping grid) or a circle of detectors or a polygonal search area.

Usage

make.grid(nx = 6, ny = 6, spacex = 20, spacey = spacex, spacing = NULL,
          detector = "multi", originxy = c(0,0), hollow = FALSE, ID = "alphay",
          leadingzero = TRUE, markocc = NULL)

make.circle (n = 20, radius = 100, spacing = NULL,
             detector = "multi", originxy = c(0,0), IDclockwise = TRUE,
             leadingzero = TRUE, markocc = NULL)

make.poly (polylist = NULL, x = c(-50,-50,50,50),
           y = c(-50,50,50,-50), exclusive = FALSE, verify = TRUE)

make.transect (transectlist = NULL, x = c(-50,-50,50,50),
               y = c(-50,50,50,-50), exclusive = FALSE)

make.telemetry (xy = c(0,0))

Arguments

nx number of columns of detectors
ny number of rows of detectors
spacex distance between detectors in ‘x’ direction (nominally in metres)
spacey distance between detectors in ‘y’ direction (nominally in metres)
spacing distance between detectors (x and y directions)
detector character value for detector type - "single", "multi" etc.
originxy vector origin for x-y coordinates
hollow logical for hollow grid
ID character string to control row names
leadingzero logical; if TRUE numeric rownames are padded with leading zeros
markocc integer vector of marking or sighting codes; see markocc
n number of detectors
radius radius of circle (nominally in metres)
IDclockwise logical for numbering of detectors
polylist list of dataframes with coordinates for polygons
transectlist list of dataframes with coordinates for transects
x x coordinates of vertices
y y coordinates of vertices
exclusive logical; if TRUE animal can be detected only once per occasion
verify logical if TRUE then the resulting traps object is checked with verify
xy vector with coordinates of arbitrary point (e.g., centroid of fixes)

Details
make.grid generates coordinates for nx.ny traps at separations spacex and spacey. If spacing is specified it replaces both spacex and spacey. The bottom-left (southwest) corner is at originxy. For a hollow grid, only detectors on the perimeter are retained. By default, identifiers are constructed from a letter code for grid rows and an integer value for grid columns ("A1", "A2",...). ‘Hollow’ grids are always numbered clockwise in sequence from the bottom-left corner. Other values of ID have the following effects:

<table>
<thead>
<tr>
<th>ID</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>numx</td>
<td>column-dominant numeric sequence</td>
</tr>
<tr>
<td>numy</td>
<td>row-dominant numeric sequence</td>
</tr>
<tr>
<td>numxb</td>
<td>column-dominant boustrophedonical numeric sequence (try it!)</td>
</tr>
<tr>
<td>numyb</td>
<td>row-dominant boustrophedonical numeric sequence</td>
</tr>
<tr>
<td>alphax</td>
<td>column-dominant alphanumeric</td>
</tr>
<tr>
<td>alphay</td>
<td>row-dominant alphanumeric</td>
</tr>
<tr>
<td>xy</td>
<td>combine column (x) and row(y) numbers</td>
</tr>
</tbody>
</table>

‘xy’ adds leading zeros as needed to give a string of constant length with no blanks.

make.circle generates coordinates for n traps in a circle centred on originxy. If spacing is specified then it overrides the radius setting; the radius is adjusted to provide the requested straightline distance between adjacent detectors. Traps are numbered from the trap due east of the origin, either clockwise or anticlockwise as set by IDclockwise.

Polygon vertices may be specified with x and y in the case of a single polygon, or as polylist for one or more polygons. Each component of polylist is a dataframe with columns ‘x’ and ‘y’. polylist takes precedence. make.poly automatically closes the polygon by repeating the first vertex if the first and last vertices differ.

Transects are defined by a sequence of vertices as for polygons, except that they are not closed.

make.telemetry builds a simple traps object for the 'telemetry' detector type. The attribute 'telemetrytype' is set to “independent”.

Specialised functions for arrays using a triangular grid are described separately (make.tri, clip.hex).

Value
An object of class traps comprising a data frame of x- and y-coordinates, the detector type ("single", "multi", or "proximity" etc.), and possibly other attributes.
Note

Several methods are provided for manipulating detector arrays - see \texttt{traps}.

Examples

demo.traps <- make.grid()
plot(demo.traps)

## compare numbering schemes
par (mfrow = c(2,4), mar = c(1,1,1,1), xpd = TRUE)
for (id in c("numx", "numy", "alphax", "alphay", "numxb", "numyb"))
{
  temptrap <- make.grid(nx = 7, ny = 5, ID = id)
  plot (temptrap, border = 10, label = TRUE, offset = 7, gridl = FALSE)
}

temptrap <- make.grid(nx = 7, ny = 5, hollow = TRUE)
plot (temptrap, border = 10, label = TRUE, gridl = FALSE)

plot(make.circle(n = 20, spacing = 30), label = TRUE, offset = 9)
summary(make.circle(n = 20, spacing = 30))

## jitter locations randomly within grid square
## and plot over `mask`
temptrap <- make.grid(nx = 7, ny = 7, spacing = 30)
templmask <- make.mask(temptrap, buffer = 15, nx = 7, ny = 7)
temptrap[,] <- temptrap[,] + 30 * (runif(7*7*2) - 0.5)
plot(templmask, dots = FALSE, mesh = 'white')
plot(temptrap, add = TRUE)
**make.tri**

*Build Detector Array on Triangular or Hexagonal Grid*

**Description**

Construct an array of detectors on a triangular grid and optionally select a hexagonal subset of detectors.

**Usage**

```r
make.tri (nx = 10, ny = 12, spacing = 20, detector = "multi",
          originxy = c(0,0))

clip.hex (traps, side = 20, centre = c(50, 60*cos(pi/6)),
          fuzz = 1e-3, ID = "num", ...)
```

**Arguments**

- `nx`: number of columns of detectors
- `ny`: number of rows of detectors
- `spacing`: distance between detectors (x and y directions)
- `detector`: character value for detector type - "single", "multi" etc.
- `originxy`: vector origin for x-y coordinates
- `traps`: traps object
- `side`: length of hexagon side
- `centre`: x-y coordinates of hexagon centre
- `fuzz`: floating point fuzz value
- `ID`: character string to control row names
- `...`: other parameters passed to subset.traps (not used)

**Details**

`make.tri` generates coordinates for `nx` `ny` traps at separations `spacing`. The bottom-left (south-west) corner is at `originxy`. Identifiers are numeric. See `make.grid` for further explanation.

`clip.hex` clips a grid of detectors, retaining only those within a bounding hexagon. Detectors are re-labelled according to `ID` as follows:

<table>
<thead>
<tr>
<th>ID</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>no change</td>
</tr>
<tr>
<td>num</td>
<td>numeric sequence</td>
</tr>
<tr>
<td>alpha</td>
<td>letter for 'shell'; number within shell</td>
</tr>
</tbody>
</table>
makeStart

Value
An object of class traps comprising a data frame of x- and y-coordinates, the detector type ("single", "multi", or "proximity" etc.), and possibly other attributes.

Note
Several methods are provided for manipulating detector arrays - see traps.

make.grid, detector

Examples

```r
tri.grid <- make.tri(spacing = 10)
plot(tri.grid, border = 5)

hex <- clip.hex(tri.grid, side = 30, ID = "alpha")
plot(hex, add = TRUE, detpar = list(pch = 16, cex = 1.4),
     label = TRUE, offset = 2.5 )
```

makeStart

Initial Parameter Values

Description
makeStart() wraps the code previously internal to secr.fit(). It will not usually be called directly.

Usage

```r
makeStart(start = NULL, parindx, capthist, mask, detectfn, link,
          details = NULL, fixed = NULL, CL = FALSE, anypoly = FALSE,
          anytrans = FALSE, alltelem = FALSE, sighting = FALSE)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>optional starting values as described for secr.fit</td>
</tr>
<tr>
<td>parindx</td>
<td>list with one component per real parameter giving corresponding indices of coefficients (beta parameters)</td>
</tr>
<tr>
<td>capthist</td>
<td>capthist object including capture data and detector (trap) layout</td>
</tr>
<tr>
<td>mask</td>
<td>mask object or (for a multi-session analysis) a list of mask objects, one for each session</td>
</tr>
</tbody>
</table>
mask

Description
Encapsulate a habitat mask for spatially explicit capture–recapture. See also secr-habitatmasks.pdf.

Details
A habitat mask serves four main purposes in spatially explicit capture–recapture. Firstly, it defines an outer limit to the area of integration; habitat beyond the mask may be occupied, but animals there should have negligible chance of being detected (see pdot and below). Secondly, it distinguishes sites in the vicinity of the detector array that are ‘habitat’ (i.e. have the potential to be occupied) from ‘non-habitat’. Thirdly, it discretizes continuous habitat as a list of points. Each point is notionally associated with a cell (pixel) of uniform density. Discretization allows the SECR likelihood to be evaluated by summing over grid cells. Fourthly, the x-y coordinates of the mask and any habitat

detectfn  integer code or character string for shape of detection function 0 = halfnormal, 1 = hazard rate etc. – see detectfn
link list of link function names ("log", "logit", "identity") for each real parameter
details list of additional arguments (see secr.fit)
fixed list with optional components corresponding to real parameters giving the scalar value to which the parameter is to be fixed
CL logical, if true then model does not include density
anypoly logical, TRUE if any polygon detectors
anytrans logical, TRUE if any transect detectors
alltelem logical, TRUE if any telemetry detectors
sighting logical, TRUE if any sighting data

Details
If ‘start’ is a previously fitted model then only ‘start’ and ‘parindx’ are required.

Value
Numeric vector with one value for each coefficient (beta parameter) in model.

See Also
secr.fit

Examples
makeStart(secr.demo.0, list(D = 1, g0 = 2:3, sigma = 4))

Description
Encapsulate a habitat mask for spatially explicit capture–recapture. See also secr-habitatmasks.pdf.

Details
A habitat mask serves four main purposes in spatially explicit capture–recapture. Firstly, it defines an outer limit to the area of integration; habitat beyond the mask may be occupied, but animals there should have negligible chance of being detected (see pdot and below). Secondly, it distinguishes sites in the vicinity of the detector array that are ‘habitat’ (i.e. have the potential to be occupied) from ‘non-habitat’. Thirdly, it discretizes continuous habitat as a list of points. Each point is notionally associated with a cell (pixel) of uniform density. Discretization allows the SECR likelihood to be evaluated by summing over grid cells. Fourthly, the x-y coordinates of the mask and any habitat
covariates may be used to build spatial models of density. For example, a continuous or categorical
habitat covariate ‘cover’ measured at each point on the mask might be used in a formula for density
such as $D \sim \text{cover}$.

In relation to the first purpose, the definition of ‘negligible’ is fluid. Any probability less than 0.001
seems OK in the sense of not causing noticeable bias in density estimates, but this depends on the
shape of the detection function (fat-tailed functions such as ‘hazard rate’ are problematic). New
tools for evaluating masks appeared in secr 1.5 (mask.check, esa.plot), and suggest.buffer
automates selection of a buffer width.

Mask points are stored in a data frame with columns ‘x’ and ‘y’. The number of rows equals the
number of points.

Possible mask attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>‘traprect’, ‘trapbuffer’, ‘pdot’, ‘polygon’, ‘clusterrect’, ‘clusterbuffer’ (see make.mask) or ‘user’</td>
</tr>
<tr>
<td>polygon</td>
<td>vertices of polygon defining habitat boundary, for type = ‘polygon’</td>
</tr>
<tr>
<td>pdotmin</td>
<td>threshold of $p(X)$ for type = ‘pdot’</td>
</tr>
<tr>
<td>covariates</td>
<td>data frame of site-specific covariates</td>
</tr>
<tr>
<td>meanSD</td>
<td>data frame with centroid (mean and SD) of x and y coordinates</td>
</tr>
<tr>
<td>area</td>
<td>area (ha) of the grid cell associated with each point</td>
</tr>
<tr>
<td>spacing</td>
<td>nominal spacing (metres) between adjacent points</td>
</tr>
<tr>
<td>boundingbox</td>
<td>data frame of 4 rows, the vertices of the bounding box of all grid cells in the mask</td>
</tr>
</tbody>
</table>

Attributes other than covariates are generated automatically by make.mask. Type ‘user’ refers to
masks input from a text file with read.mask.

A virtual S4 class ‘mask’ is defined to allow the definition of a method for the generic function
raster from the raster package.

Note

A habitat mask is needed by secr.fit, but one will be generated automatically if none is provided.
You should be aware of this and check that the default settings (e.g. buffer) are appropriate.

---

mask.check

Mask Diagnostics

Description

mask.check evaluates the effect of varying buffer width and mask spacing on either the likelihood
or density estimates from secr.fit().
Usage

mask.check(object, buffers = NULL, spacings = NULL, poly = NULL,
LLonly = TRUE, realpar = NULL, session = 1, file = NULL,
drop = "", tracelevel = 0, ...)

Arguments

object object of class ‘capthist’ or ‘secr’
buffers vector of buffer widths
spacings vector of mask spacings
poly matrix of two columns, the x- and y-coordinates of a bounding polygon (optional)
LLonly logical; if TRUE then only the log likelihood is computed
realpar list of parameter values
session vector of session indices (used if object spans multiple sessions)
file name of output file (optional)
drop character vector: names of fitted secr object to omit
tracelevel integer for level of detail in reporting (0,1,2)
... other arguments passed to secr.fit

details

Masks of varying buffer width and spacing are constructed with the ‘trapbuffer’ method in make.mask, using the detector locations (‘traps’) from either a capthist object or a previous execution of secr.fit. Default values are provided for buffers and spacings if object is of class ‘secr’ (respectively c(1, 1.5, 2) and c(1, 0.75, 0.5) times the values in the existing mask). The default for buffers will not work if a detector is on the mask boundary, as the inferred buffer is then 0.

Variation in the mask may be assessed for its effect on –

• the log-likelihood evaluated for given values of the parameters (LLonly = TRUE)
• estimates from maximizing the likelihood with each mask (LLonly = FALSE)

realpar should be a list with one named component for each real parameter (see Examples). It is relevant only if LLonly = TRUE. realpar may be omitted if object is of class ‘secr’; parameter values are then extracted from object.

session should be an integer or character vector suitable for indexing sessions in object, or in object$capthist if object is a fitted model. Each session is considered separately; a model formula that refers to session or uses session covariates will cause an error.

If file is specified then detailed results (including each model fit when LLonly = FALSE) are saved to an external .RData file. Loading this file creates or overwrites object(s) in the workspace: mask.check.output if LLonly = TRUE, otherwise mask.check.output and mask.check.fit. For multiple sessions these are replaced by lists with one component per session (mask.check.outputs and mask.check.fits). The drop argument is passed to trim and applied to each fitted model; use it to save space, at the risk of limiting further computation on the fitted models.
tracelevel>0 causes more verbose reporting of progress during execution.

The ... argument may be used to override existing settings in object - for example, a conditional likelihood fit (CL = T) may be selected even if the original model was fitted by maximizing the full likelihood.

Value

Array of log-likelihoods (LLonly = TRUE) or estimates (LLonly = FALSE) for each combination of buffers and spacings. The array has 3 dimensions if LLonly = FALSE and both buffers and spacings have multiple levels; otherwise it collapses to a matrix. Rows generally represent buffers, but rows represent spacings if a single buffer is specified.

Warning

mask.check() may fail if object is a fitted ‘secr’ model and a data object named in the original call of secr.fit() (i.e. object$call) is no longer in the working environment (secr.fit arguments capthist, mask, verify & trace are exempt). Fix by any of (1) applying mask.check directly to the ‘capthist’ object, specifying other arguments (buffers, spacings, realpar) as needed, (2) re-fitting the model and running mask.check in the same environment, (3) specifying the offending argument(s) in ..., or (4) re-creating the required data objects(s) in the working environment, possibly from saved inputs in object (e.g., mytimecov <- myfit$timecov).

Note

When LLonly = TRUE the functionality of mask.check resembles that of the ‘Tools | ML SECR log likelihood’ menu option in Density 5. The help page in Density 5 for ML SECR 2-D integration (see index) may be helpful.

Warning messages from secr.fit are suppressed. ‘capthist’ data provided via the object argument are checked with verify.capthist if tracelevel > 0.

The likelihood-only method is fast, but not definitive. It is reasonable to aim for stability in the third decimal place of the log likelihood. Slight additional variation in the likelihood may cause little change in the estimates; the only way to be sure is to check these by setting LLonly = FALSE.

The performance of a mask depends on the detection function; be sure to set the detectfn argument appropriately. The hazard rate function has a fat tail that can be problematic.

When provided with an ‘secr’ object, mask.check constructs a default vector of buffer widths as multiples of the buffer used in object even though that value is not saved explicitly. For this trick, detector locations in traps(object$capthist) are compared to the bounding box of object$mask; the base level of buffer width is the maximum possible within the bounding box.

       gridlines = FALSE)
  plot(mask.check.fit[[i]]$mask, add = TRUE)
  lines(possumarea)
  text (2698618, 6078427, names(mask.check.fit)[i])
  box()}
AIC- or AICc-weighted average of estimated ‘real’ or ‘beta’ parameters from multiple fitted secr models, and the tabulation of estimates.

## Usage

```
## S3 method for class 'secr'
modelAverage(object, ..., realnames = NULL, betanames = NULL, newdata = NULL, alpha = 0.05, dmax = 10, covar = FALSE, average = c("link", "real"), criterion = c("AICc","AIC"), CImethod = c("Wald", "MATA"), chat = NULL)
```

```
## S3 method for class 'secrlist'
modelAverage(object, ..., realnames = NULL, betanames = NULL, newdata = NULL, alpha = 0.05, dmax = 10, covar = FALSE, average = c("link", "real"), criterion = c("AICc","AIC"), CImethod = c("Wald", "MATA"), chat = NULL)
```

### Arguments

- **object**: secr or secrlist object
- **...**: other secr objects
- **realnames**: character vector of real parameter names
- **betanames**: character vector of beta parameter names
- **newdata**: optional dataframe of values at which to evaluate models
- **alpha**: alpha level for confidence intervals
- **dmax**: numeric, the maximum AIC or AICc difference for inclusion in confidence set
- **covar**: logical, if TRUE then return variance-covariance matrix
- **average**: character string for scale on which to average real parameters
- **criterion**: character, information criterion to use for model weights
- **CImethod**: character, type of confidence interval (see Details)
- **chat**: numeric optional variance inflation factor for quasi-AIC weights
Details

Models to be compared must have been fitted to the same data and use the same likelihood method (full vs conditional). If `realnames = NULL` and `betanames = NULL` then all real parameters will be averaged; in this case all models must use the same real parameters. To average beta parameters, specify `betanames` (this is ignored if a value is provided for `realnames`). See `predict.secr` for an explanation of the optional argument `newdata`; `newdata` is ignored when averaging beta parameters.

Model-averaged estimates for parameter $\theta$ are given by

$$\hat{\theta} = \sum_k w_k \hat{\theta}_k$$

where the subscript $k$ refers to a specific model and the $w_k$ are AIC or AICc weights (see `AIC.secr` for details). Averaging of real parameters may be done on the link scale before back-transformation (`average = "link"`) or after back-transformation (`average = "real"`).

Models for which $\text{dAIC} > \text{dmax}$ (or $\text{dAICc} > \text{dmax}$) are given a weight of zero and effectively are excluded from averaging.

Also,

$$\text{var}(\hat{\theta}) = \sum_k w_k (\text{var}(\hat{\theta}_k | \beta_k) + \beta_k^2)$$

where $\hat{\beta}_k = \hat{\theta}_k - \hat{\theta}$ and the variances are asymptotic estimates from fitting each model $k$. This follows Burnham and Anderson (2004) rather than Buckland et al. (1997).

Two methods are offered for confidence intervals. The default ‘Wald’ uses the above estimate of variance. The alternative ‘MATA’ (model-averaged tail area) avoids estimating a weighted variance and is thought to provide better coverage at little cost in increased interval length (Turek and Fletcher 2012). Turek and Fletcher (2012) also found averaging with AIC weights (here `criterion = "VarAIC"`) preferable to using AICc weights, even for small samples. `CI.method` does not affect the reported standard errors.

If ‘chat’ is provided then quasi-AIC or quasi-AICc weights are used, depending on the value of ‘criterion’.

Value

For `modelAverage`, an array of model-averaged estimates, their standard errors, and a $100(1 - \alpha)\%$ confidence interval. The interval for real parameters is backtransformed from the link scale. If there is only one row in `newdata` or beta parameters are averaged or averaging is requested for only one parameter then the array is collapsed to a matrix. If `covar = TRUE` then a list is returned with separate components for the estimates and the variance-covariance matrices.

Note

`modelAverage` replaces the deprecated function `model.average` whose name conflicted with a method in `RMark`.

`modelAverage`, `AIC.secr`, `secr.fit`, `collate`

**Examples**

```r
## Compare two models fitted previously
## secrdemo.0 is a null model
## secrdemo.b has a learned trap response

modelAverage(secrdemo.0, secrdemo.b)
modelAverage(secrdemo.0, secrdemo.b, betanames = c("D","g0","sigma"))

## In this case we find the difference was actually trivial...
## (subscripting of output is equivalent to setting fields = 1)
```

---

### ms

**Multi-session Objects**

**Description**

Logical function to distinguish objects that span multiple sessions

**Usage**

```r
## Default S3 method:
ms(object, ...)
## S3 method for class 'mask'
ms(object, ...)
## S3 method for class 'secr'
ms(object, ...)
```

**Arguments**

- `object` any object
- `...` other arguments (not used)
Details

The test applied varies with the type of object. The default method uses `inherits(object, "list")`.

Value

logical, TRUE if object contains data for multiple sessions

See Also

capthist, mask, secr.fit

Examples

```r
ms(ovenCH)
ms(ovenbird.model.1)
ms(ovenCH[[1]])
```

---

Create Default Design Data

Description

Internal function used to generate a dataframe containing design data for the base levels of all predictors in an secr object.

Usage

```r
## Default S3 method:
makeNewData(object, all.levels = FALSE, ...)
## S3 method for class 'secr'
makeNewData(object, all.levels = FALSE, ...)
```

Arguments

- `object` fitted secr model object
- `all.levels` logical; if TRUE then all levels of factors are included
- `...` other arguments (not used)

Details

`makeNewData` is used by `predict` in lieu of user-specified `newdata`. There is seldom any need to call the function `makeNewData` directly.
Value

A dataframe with one row for each session and group, and columns for the predictors used by object$model.

See Also

predict.secr, secr.fit

Examples

```r
## from previously fitted model
makeNewData(secrdemo.b)
```

---

**nontarget**  

**Non-target Data**

Description

Non-target detections and interference events may be recorded in a binary detector x occasion matrix attached as an attribute to a single-session capthist object, or to each component of a multi-session capthist object.

Models fitted by secr make no use of these data. They may be used in ipsecr.

From secr 4.5.6, a summary of nontarget data is reported by the summary method for capthist objects, and the verify method reports clashes between detections and nontarget data.

Extraction and replacement functions are provided from secr 4.5.7 on.

Usage

```r
nontarget(object, ...)  
nontarget(object) <- value
```

Arguments

- `object`: capthist object
- `...`: other arguments (not used)
- `value`: numeric binary matrix (rows = detectors, columns = occasions)

Details

The order of rows should match the order of detectors in traps(object). Matrix entries should be zero for trap x occasion combinations that were not used (see usage) or for which there is a corresponding detection.

value is coerced to a matrix before assignment.
Value

For \texttt{nontarget()}, a matrix or list of matrices.

See Also

\texttt{plot.capthist, summary.capthist}

Examples

```r
set.seed(123)
ch <- capthdata

# traps that caught something
cought <- t(apply(ch, 2:3, sum))

# construct artificial nontarget data
# (positive for half the traps that caught nothing)
nontarget(ch) <- (1-cought) * (runif(500)>0.5)

head(cought)
head(nontarget(ch))

# the summary method recognises the 'nontarget' attribute
summary(ch)$nontarget
```

occasionKey

\textit{Key to Petal Plot}

Description

Displays a graphic key to the occasions corresponding to petals in a petal plot.

Usage

\texttt{occasionKey(capthist, noccasions, rad = 3, x, y, px = 0.9, py = 0.9,
\hspace{1em} title = 'Occasion', ...)}

Arguments

- \texttt{capthist} \hspace{1em} single-session capthist object
- \texttt{noccasions} \hspace{1em} number of petals (if capthist not provided)
- \texttt{rad} \hspace{1em} distance of petal centre from key centre
- \texttt{x} \hspace{1em} numeric x coordinate for centre of key
- \texttt{y} \hspace{1em} numeric y coordinate for centre of key
- \texttt{px} \hspace{1em} x position as fraction of user coordinates
ovenbird

py y position as fraction of user coordinates
title character
... other arguments passed to text

Details

Either capthist or nooccasions is required. It is assumed that a plot exists.

Graphic arguments in ... are applied to both the title and the occasion numbers.

Value

The key will be added to an existing plot. No value is returned.

See Also

plot.capthist

Examples

plot(captdata, border = 50)
occasionKey(captdata, rad = 8, cex = 0.8)

ovenbird

Ovenbird Mist-netting Dataset

Description

Data from a multi-year mist-netting study of ovenbirds (Seiurus aurocapilla) at a site in Maryland, USA.

Usage

ovenCH
ovenCHp
ovenbird.model.1
ovenbird.model.D
ovenmask
Details

From 2005 to 2009 D. K. Dawson and M. G. Efford conducted a capture–recapture survey of breeding birds in deciduous forest at the Patuxent Research Refuge near Laurel, Maryland, USA. The forest was described by Stamm, Davis & Robbins (1960), and has changed little since. Analyses of data from previous mist-netting at the site by Chan Robbins were described in Efford, Dawson & Robbins (2004) and Borchers & Efford (2008).

Forty-four mist nets (12 m long, 30-mm mesh) spaced 30 m apart on the perimeter of a 600-m x 100-m rectangle were operated for approximately 9 hours on each of 9 or 10 non-consecutive days during late May and June in each year. Netting was passive (i.e. song playback was not used to lure birds into the nets). Birds received individually numbered bands, and both newly banded and previously banded birds were released at the net where captured. Sex was determined in the hand from the presence of a brood patch (females) or cloacal protuberance (males). A small amount of extra netting was done by other researchers after the main session in some years.

This dataset comprises all records of adult (after-hatch-year) ovenbirds caught during the main session in each of the five years 2005–2009. One ovenbird was killed by a predator in the net in 2009, as indicated by a negative net number in the dataset. Sex was determined in the hand from the presence of a brood patch (females) or cloacal protuberance (males). Birds are listed by their band number (4-digit prefix, '.', and 5-digit number).

The data are provided as a multi-session capthist object ‘ovenCHp’. Sex is coded as a categorical individual covariate ("M" or "F").

Recaptures at the same site within a day are not included in this dataset, so ovenCHp has detector type ‘proximity’. Previous versions of secr provided only a trimmed version of these data, retaining only one capture per bird per day (ovenCH with detector type ‘multi’). That may be obtained from ovenCHp as shown in the examples.

Although several individuals were captured in more than one year, no use is made of this information in the analyses presently offered in secr.

An analysis of the data for males in the first four years showed that they tended to avoid nets after their first capture within a season (Dawson & Efford 2009). While the species was present consistently, the number of detections in any one year was too small to give reliable estimates of density; pooling of detection parameters across years helped to improve precision.

Included with the data are a mask and two models fitted to ovenCH as in Examples.

### ovensong

*Ovenbird Acoustic Dataset*

#### Description

Data from an acoustic survey of ovenbirds (*Seiurus aurocapilla*) at a site in Maryland, USA.

#### Usage

- `signalCH`
- `ovensong.model.1`
- `ovensong.model.2`

#### Details

In June 2007 D. K. Dawson and M. G. Efford used a moving 4-microphone array to survey breeding birds in deciduous forest at the Patuxent Research Refuge near Laurel, Maryland, USA. The data for ovenbirds were used to demonstrate a new method for analysing acoustic data (Dawson and Efford 2009). See `ovenbird` for mist-netting data from the same site over 2005–2009, and for other background.

Over five days, four microphones were placed in a square (21-m side) centred at each of 75 points in a rectangular grid (spacing 50 m); on each day points 100 m apart were sampled sequentially. Recordings of 5 minutes duration were made in .wav format on a 4-channel digital sound recorder.

The data are estimates of average power on each channel (microphone) for the first song of each ovenbird distinguishable in a particular 5-minute recording. Power was estimated with the sound analysis software Raven Pro 1.4 (Charif et al. 2008), using a window of 0.7 s duration and frequencies between 4200 and 5200 Hz, placed manually at the approximate centre of each ovenbird song. Sometimes this frequency range was obscured by insect noise so an alternative 1000-Hz range was measured and the values were adjusted by regression.

The data are provided as a single-session, single-occasion capthist object `signalCH`. The ‘signal’ attribute contains the power measurement in decibels for each detected sound on each channel where the power threshold is exceeded. As the threshold signal (attribute `cutval = 35`) is less than any signal value in this dataset, all detection histories are complete (1,1,1,1) across microphones. For analysis Dawson and Efford applied a higher threshold that treated weaker signals as ‘not detected’ (see Examples).
The row names of `signalCH` (e.g. "3755AX") are formed from a 4-digit number indicating the sampling location (one of 75 points on a 50-m grid) and a letter A–D to distinguish individual ovenbirds within a 5-minute recording; 'X' indicates power values adjusted by regression.

The default model for sound attenuation is a log-linear decline with distance from the source (linear decline on dB scale). Including a spherical spreading term in the sound attenuation model causes the likelihood surface to become multimodal in this case. Newton-Raphson, the default maximization method in `secr.fit`, is particularly inclined to settle on a local maximum; in the example below we use a set of starting values that have been found by trial and error to yield the global maximum. Two fitted models are included (see Examples for details).

OVpossum

Orongorongo Valley Brushtail Possums

Description

A dataset from long-term capture-recapture trapping of brushtail possums *Trichosurus vulpecula* in New Zealand.

Usage

OVpossumCH

Format

Details

Brushtail possums are 2-4 kg largely arboreal marsupials that have become pests of forests and farmland in New Zealand since their introduction from Australia in the nineteenth century. Their population dynamics in mixed native forest have been studied by capture-recapture in the Orongorongo Valley near Wellington since 1966 (e.g. Crawley 1973, Efford 1998, Efford and Cowan 2004).
From 1996 to 2006, a grid of 167 traps set on the ground at 30-m spacing was operated in an area of about 14 ha for 5 consecutive days three times each year (Efford and Cowan 2004). Each trap could catch only one animal, with rare exceptions when a young ‘backrider’ entered the trap with its mother. All animals were tagged and tattooed for individual identification and released at the site of capture.

A broad shingle riverbed forms a natural boundary on two sides of the study grid. Much of the grid lies on a gently sloping old alluvial fan and recent terraces, but to the southeast the valley side rises steeply and, except where cut by streams, supports beech forest (Nothofagus truncata and Nothofagus solandri solandri) rather than the mixed broadleaf forest of the valley floor.

This dataset relates to six five-day trapping sessions in 1996 and 1997, a time of high and declining density. Possums are long-lived (up to about 15 years) and as adults restrict their movements to a home range of 1-10 ha. Breeding is seasonal, resulting in an influx of newly independent juveniles in the first trapping of each calendar year.

The dataset includes individual covariates not provided by Efford (2012): ‘sex’ (F or M) and ‘Age-class’ (1 for first year, 2 for older).

A coarse habitat map is provided for the immediate vicinity of the trapping grid as the shapefile ‘OVforest.shp’ in the package ‘extdata’ folder. This distinguishes two forest classes (‘beech’ and ‘non-beech’), and leaves out the shingle riverbed. The distinction between ‘beech’ and ‘non-beech’ is mapped only to a distance of about 120 m from the outermost traps. A text file ‘leftbank.txt’ in the same folder contains the x- and y- coordinates of the adjoining bank of the Orongorongo River. All coordinates relate to the old New Zealand Map Grid (NZMG), since replaced by the New Zealand Transverse Mercator grid (NZTM2000).

The example code shows how to import the shapefile as a sp SpatialPolygonsDataFrame object and use it to construct a mask for secr.fit.

Source

Efford (2012) and unpublished data.

---

**par.secr.fit**

**Fit Multiple SECR Models**

**Description**

These functions are wrappers for `secr.fit`, `region.N` and `derived` that allow multiple models to be fitted simultaneously on multi-core machines (but see Warning).

**Usage**

```r
par.secr.fit (arglist, ncores = 1, seed = NULL, trace = TRUE, logfile = "logfile.txt",
             prefix = "fit.", LB = FALSE, save.intermediate = FALSE)
par.derived (secrlist, ncores = 1, ...)
```
par.secr.fit

par.region.N (secrlist, ncores = 1, ...)  

Arguments

arglist list of argument lists for secr.fit or a character vector naming such lists
ncores integer number of cores to be used for parallel processing
seed integer pseudorandom number seed
trace logical; if TRUE intermediate output may be logged
logfile character name of file to log progress reports
prefix character prefix for names of output
LB logical; if TRUE then use load balancing
save.intermediate logical; if TRUE then each fit is saved to an external file
... other arguments passed to derived or region.N
secrlist secrlist object

Details

From version 4.0, an arglist may specify ncores for a particular secr.fit (previously ncores was ignored in arglist).

trace overrides any settings in arglist. Reporting of intermediate results is unreliable on Windows when ncores > 1.

It is convenient to provide the names of the capthist and mask arguments in each component of arglist as character values (i.e. in quotes); objects thus named are exported from the workspace to each worker process (see Examples).

Setting LB = TRUE when ncores > 1 causes the function to call clusterApplyLB instead of clusterApply. Load balancing in clusterApplyLB is likely to result in faster completion than the default if fits differ in their in execution time and ncores < length(arglist), but this cannot be guaranteed owing to the additional communication required with the worker processes. Results with LB = TRUE for a given seed may not be reproducible.

save.intermediate causes each fit to be saved to a file with extension .RData.

Value

For par.secr.fit - secrlist of model fits (see secr.fit). Names are created by prefixing prefix to the names of arglist. If trace is TRUE then the total execution time and finish time are displayed.

For par.derived - a list of dataframes output from derived, applied to each model in turn.

For par.region.N - a list of dataframes output from region.N, applied to each model in turn.

Warning

With the introduction of multi-threading in secr 4.0, par.secr.fit has lost its speed advantage.
Parallel

par.derived(fits, se.esa = FALSE)
par.region.N(fits)

## End(Not run)

Parallel Multi-core Processing

Description

From version 4.0 secr uses multi-threading in C++ (package RcppParallel, Allaire et al. 2021) to speed likelihood evaluation and hence model fitting in sect.fit. Detection histories are distributed over threads. Setting ncores = NULL in functions with multi-threading uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).

These functions use multi-threading and call setNumThreads internally:

autoini
confint.secr
derived.secr
derivedSystematic
esafxi.secr and related functions
pdot
region.N
score.test
secr.fit

These functions use multi-threading without calling setNumThreads:

LLsurface.secr
Other functions may use multithreading indirectly through a call to one of these functions. Examples are `suggest.buffer` (autoini), `esa.plot` (pdot), and `bias.D` (pdot).

NOTE: The mechanism for setting the number of threads changed between versions 4.1.0 and 4.2.0. The default number of cores is now capped at 2 to meet CRAN requirements. Setting `ncores = NULL` previously specified one less than the maximum number of cores.

Earlier versions of secr made more limited use of multiple cores (CPUs) through the package parallel. This mechanism is still available in the functions listed here, but the speed gains are often small or even negative. Set `ncores > 1` in the function call to use multiple cores.

<table>
<thead>
<tr>
<th>Function</th>
<th>Unit</th>
<th>Benefit</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>

<td><code>par.derived</code></td>
<td>fitted model</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td><code>par.region.N</code></td>
<td>fitted model</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

‘Unit’ refers to the unit of work sent to each worker process. As a guide, a ‘large’ benefit means >60% reduction in process time with 4 CPUs.

parallel offers several different mechanisms, bringing together the functionality of multicore and snow. The mechanism used by secr is the simplest available, and is expected to work across all operating systems. Technically, it relies on Rscript and communication between the master and worker processes is via sockets. As stated in the parallel documentation "Users of Windows and Mac OS X may expect pop-up dialog boxes from the firewall asking if an R process should accept incoming connections". You may possibly get warnings from R about closing unused connections. These can safely be ignored.

Use `parallel::detectCores()` to get an idea of how many cores are available on your machine; this may (in Windows) include virtual cores over and above the number of physical cores. See `RShowDoc("parallel", package = "parallel")` in core R for explanation.

In secr.fit the output component ‘proctime’ misrepresents the elapsed processing time when multiple cores are used.

Warning

It appears that multicore operations in secr using parallel may fail if the packages snow and snowfall are also loaded. The error message is obscure:

“Error in UseMethod("sendData") : no applicable method for ’sendData’ applied to an object of class "SOCK0node"”
**Parallel**

pdot

Net Detection Probability

Description

Compute spatially explicit net probability of detection for individual(s) at given coordinates (pdot).

Usage

pdot(X, traps, detectfn = 0, detectpar = list(g0 = 0.2, sigma = 25, z = 1), noccasions = NULL, binomN = NULL, userdist = NULL, ncores = NULL)

CVpdot(..., conditional = FALSE)

Arguments

X vector or 2-column matrix of coordinates
traps traps object
detectfn integer code for detection function q.v.
detectpar a named list giving a value for each parameter of detection function
noccasions number of sampling intervals (occasions)
binomN integer code for discrete distribution (see secr.fit)
userdist user-defined distance function or matrix (see userdist)
ncores integer number of threads
... arguments passed to pdot
conditional logical; if TRUE then computed mean and CV are conditional on detection

Details

If traps has a usage attribute then noccasions is set accordingly; otherwise it must be provided. The probability computed is \( p(X) = 1 - \prod_k \{1 - \mu_s(X, k)\}^5 \) where the product is over the detectors in traps, excluding any not used on a particular occasion. The per-occasion detection function \( \mu_s \) is halfnormal (0) by default, and is assumed not to vary over the \( S \) occasions.

For detection functions (10) and (11) the signal threshold ‘cutval’ should be included in detectpar, e.g., detectpar = list(beta0 = 103, beta1 = -0.11, sdS = 2, cutval = 52.5).

The calculation is not valid for single-catch traps because \( p(X) \) is reduced by competition between animals.

userdist cannot be set if ‘traps’ is any of polygon, polygonX, transect or transectX. if userdist is a function requiring covariates or values of parameters ‘D’ or ‘noneuc’ then \( X \) must have a covariates attribute with the required columns.

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).

CVpdot returns the expected mean and CV of pdot across the points listed in \( X \), assuming uniform population density. \( X \) is usually a habitat mask. See Notes for details.

Value

For pdot, a vector of probabilities, one for each row in \( X \).
For CVpdot, a named vector with elements ‘meanpdot’ and ‘CVpdot’.

Note

CVpdot computes the mean \( \mu \) and variance \( V \) of the location-specific overall detection probability \( p(X) \) as follows.

\[
\mu = \int p(X)f(X)dX,
\]
\[
V = \int p(X)^2f(X)dX - \mu^2.
\]

For uniform density and conditional = FALSE, \( f(X) \) is merely a scaling factor independent of \( X \).
If conditional = TRUE then \( f(X) = p(X)/\int p(X)dX \).
The coefficient of variation is \( CV = \sqrt{V}/\mu \).
PG

Telemetry Fixes in Polygons

Description

For a telemetry dataset, either as a standalone captist object with detector type 'telemetryonly' or the xylist attribute of a combined captist object resulting from addTelemetry, determine the proportion of fixes of each individual that lie within a set of polygons. Typically used to obtain the proportion of fixes on a trapping grid, hence ‘proportion on grid’.

Usage

```r
PG(CH, poly = NULL, includeNULL = FALSE, plt = FALSE, ...)  
```

Arguments

- **CH**: captist object including telemetry locations
- **poly**: polygon object (see `boundarytoSF`)
- **includeNULL**: logical; if TRUE then missing values are returned for animals without telemetry data
- **plt**: logical; if TRUE then poly and telemetry locations are plotted
- **...**: other arguments passed to `buffer.contour`
Details

By default poly is obtained by applying `buffer.contour` with arguments ... to the traps attribute of CH. Note that either a positive buffer argument or `convex = TRUE` is needed for the polygon to have area > 0.

If `plt = TRUE`, `buffer.contour` is used to plot poly and the points are overplotted (open circles outside, filled circles inside). To control the framing of the plot, create an initial plot (e.g., with `plot.traps`, setting the border argument) and use `add = TRUE` (see Examples).

Value

Numeric vector of proportions. If `includeNULL = TRUE` length equal to number of animals (rows) in CH; otherwise length is the number of animals for which there is telemetry data (because xylist may cover only a subset of animals in CH).

plotMCP(x, add = FALSE, col = "black", fill = NA, lab1cap = FALSE, laboffset = 4,
ncap = FALSE, ...)

Arguments

x an object of class capthist
rad radial displacement of dot indicating each capture event from the detector location (used to separate overlapping points)
hidetraps logical indicating whether trap locations should be displayed
tracks logical indicating whether consecutive locations of individual animals should be joined by a line
title logical or character string for title
subtitle logical or character string for subtitle
add logical for whether to add to existing plot
varycol logical for whether to distinguish individuals by colour
icolours vector of individual colours (when varycol = TRUE), or colour scale (non-petal plots)
randcol logical to use random colours (varycol = TRUE)
lab1cap logical for whether to label the first capture of each animal
laboffset distance by which to offset labels from points
ncap logical to display the number of detections per trap per occasion
splitocc optional occasion from which second colour is to be used
col2 second colour (used with splitocc)
type character string ("petal", "n.per.detector" or "n.per.cluster")
cappar list of named graphical parameters for detections (passed to par)
trkpar list of named graphical parameters for tracks (passed to par)
labpar list of named graphical parameters for labels (passed to par)
... arguments to be passed to plot.traps
col vector of line colour numbers or names (plotMCP only)
fill vector of fill colour numbers or names (plotMCP only)
plot.capthist

Details

By default, a ‘petal’ plot is generated in the style of Density (Efford 2012) using eqscplot from the MASS library.

If type = "n.per.detector" or type = "n.per.cluster" the result is a colour-coded plot of the number of individuals at each unit, pooled over occasions.

If type = "sightings" the sightings of unmarked animals are displayed on a petal-like plot (requires mark-resight data) (see also sightingPlot).

If type = "centres" then a single point is plotted for each animal, jittered on each axis by a random amount (limits +/- rad/2).

If type = "telemetry" and the ‘telemetryxy’ attribute is not NULL then the telemetry locations are plotted.

If type = "nontarget" and the ‘nontarget’ attribute is not NULL then the nontarget captures or interference events are plotted.

If title = FALSE no title is displayed; if title = TRUE, the session identifier is used for the title.

If subtitle = FALSE no subtitle is displayed; if subtitle = TRUE, the subtitle gives the numbers of occasions, detections and individuals.

If x is a multi-session capthist object then a separate plot is produced for each session. Use `par(mfrow = c(nr, nc))` to allow a grid of plots to be displayed simultaneously (nr rows x nc columns).

These arguments are used only for petal plots: rad, tracks, varycol, randcol, lab1cap, laboffset, ncap, splitocc, col2, trkpar, and labpar. Call `occasionKey` to add a key to the petals.

If icolours = NULL and varycol = TRUE then a vector of colours is generated automatically as topo.colors((nrow(x)+1) * 1.5). If there are too few values in icolours for the number of individuals then colours will be re-used.

The MCP plots minimum convex polygons of individual location data over a base plot of detector locations. Usually the data are telemetry locations in the xylist attribute of the capthist object; if this is not present and x is a polygon search capthist then the individual xy data are plotted.

Value

For type = "petal", the number of detections in x. For type = "sightings", the number of sightings of unmarked animals in x. For type = "n.per.detector" or type = "n.per.cluster", a dataframe with data for a legend (see Examples).

plotMCP invisibly returns a list in which each component is a 2-column (x,y) dataframe of boundary coordinates for one individual.

## simple "centres" example
## polygon data require 'hazard' detection function 14:19
CH <- sim.capthist(make.poly(), nocc = 20, detectfn = "HHN", detectpar = list(lambda0 = 1, sigma = 10))
### Description

Plot a habitat mask either as points or as an image plot. Colours maybe used to show the value of one mask covariate.

### Usage

```r
## S3 method for class 'mask'
plot(x, border = 20, add = FALSE, covariate = NULL, axes = FALSE,
dots = TRUE, col = "grey", breaks = 10, meshcol = NA, ppoly = TRUE,
polycol = "red", legend = TRUE, ...)
```

```r
## S3 method for class 'Dsurface'
plot(x, covariate, group = NULL, plottype =
   "shaded", scale = 1, ...)
```

```r
## S3 method for class 'Rsurface'
plot(x, covariate = "Resource", plottype =
   "shaded", scale = 1, ...)
```

```r
spotHeight (object, prefix = NULL, dec = 2, point = FALSE, text = TRUE,
sep = ",", session = 1, scale = 1, ...)
```

### Arguments

- `x`, `object` mask or Dsurface object
- `border` width of blank display border (metres)
- `add` logical for adding mask points to an existing plot
- `covariate` name (as character string in quotes) or column number of a covariate to use for colouring
- `axes` logical for plotting axes
- `dots` logical for plotting mask points as dots, rather than as square pixels
- `col` colour(s) to use for plotting
- `breaks` an integer or a numeric vector – see `cut`
- `meshcol` colour for pixel borders (NA for none)
ppoly logical for whether the bounding polygon should be plotted (if ‘poly’ specified)
polycol colour for outline of polygon (ppoly = TRUE)
legend logical; if TRUE a legend is plotted
... other arguments passed to eqscplot (in the case of plot.mask), plot.mask (in the case of plot.Dsurface and plot.Rsurface), and points or text (in the case of spotHeight)
group group for which plot required, if more than 1
plottype character string c("dots", "shaded", "contour", "persp")
scale numeric multiplier for density or other numeric covariate (see Dsurface)
prefix character vector for name(s) of covariate(s) to retrieve
dec number of decimal places for rounding density
point logical for whether to plot point
text logical for whether to place density label on plot
sep character separator for elements if length(prefix)>1
session session number or identifier

Details

The argument dots of plot.mask selects between two distinct types of plot (dots and shaded (coloured) pixels).

plot.Dsurface and plot.Rsurface offer contour and perspective plots in addition to the options in plot.mask. It may take some experimentation to get what you want - see contour and persp.

For plot.Dsurface the default value of ‘covariate’ is ‘D’ unless the Dsurface has a ‘parameter’ attribute of ‘noneuc’.

If using a covariate or Dsurface or Rsurface to colour dots or pixels, the col argument should be a colour vector of length equal to the number of levels (the default palette from 2.9.0 is terrain.colors, and this palette will also be used whenever there are too few levels in the palette provided; see Notes for more on palettes). Border lines around pixels are drawn in ‘meshcol’. Set this to NA to eliminate pixel borders.

If a covariate is specified in a call to plot.Dsurface then that covariate will be plotted instead of density. This is a handy way to contour a covariate (contouring is not available in plot.mask).

If ‘breaks’ is an integer then the range of the covariate is divided into this number of equal intervals. Alternatively, ‘breaks’ may be a vector of break points (length one more than the number of intervals). This gives more control and often ‘prettier’

spotHeight may be used to interrogate a plot produced with plot.Dsurface or plot.Rsurface, or by plot.mask if the mask has covariates. prefix defaults to ‘density.’ for Dsurface objects and to ‘’ (all covariates) for mask objects. The predicted density or covariate at the nearest point is returned when the user clicks on the plot. Multiple values may be displayed (e.g., prefix = c("lcl", "uc1") if Dsurface includes confidence limits). Click outside the mask or hit the Esc key to end. spotHeight deals with one session at a time.

Legend plotting is enabled only when a covariate is specified. It uses legend when dots = TRUE and strip.legend otherwise.
plot.mask

Value

If covariate is specified and plottype = "shaded" then plot.mask invisibly returns a character vector of the intervals defined by 'breaks' (useful for plotting a legend).

If plottype = "persp" then plot.mask invisibly returns a the perspective matrix that may be used to add to the plot with trans3d.

spotHeight invisibly returns a dataframe of the extracted values and their coordinates.

Note

plot.mask() acquired the argument 'legend' in version 2.9.0, and other changes (e.g., breaks = 10) may alter the output.

Contouring requires a rectangular grid; if a Dsurface is not rectangular then plot.Dsurface with plottype = "contour" triggers a call to rectangularMask.

The colour palettes topo.colors, heat.colors and terrain.colors may be viewed with the demo.pal function in the Examples code of their help page palettes.

The package RColorBrewer is a good source of palettes. Try display.brewer.all() and e.g., col = brewer.pal(7, "YlGn").

  paste(zlev,"--"), y.intersp = 1, title = "Density / ha")

## End(Not run)

---

plot.popn  
**Plot Population Object**

**Description**

Display animal locations from a popn object.

**Usage**

```r
## S3 method for class 'popn'
plot(x, add = FALSE, frame = TRUE,
circles = NULL, collapse = FALSE, seqcol = NULL, ...)
```

**Arguments**

- `x`  
  object of class popn
- `add`  
  logical to add points to an existing plot
frame logical to add frame or polygon within which points were simulated
circles vector giving the radii if circles are to be plotted
collapse logical; if TRUE then multiple sessions are overlaid
seqcol color used for first detection when collapse = TRUE (optional)
... arguments passed to eqscplot and points or symbols

Details

If circles is provided then a circle of the given radius is plotted for each animal using the symbols function. The arguments fg and bg may be used to control the colour of the perimeter and the fill of each circle (see Examples).

For a multi-session popn with turnover, collapse = TRUE allows successive locations to be joined with (type = 'o' or type = 'l').

seqcol may be a single color, a vector of colours (one per session), or a vector of two colours, one for the first and one for all later sessions in which each animal was detected.

If ...includes 'col' then 'collapse' must be specified to avoid confusion, even for single-session data (see Examples).

Examples

temppopn <- sim.popn(D = 5, expand.grid(
  x = c(0,100), y = c(0,100)))
# specify collapse to avoid partial match of col
plot(temppopn, pch = 16, collapse = FALSE, col = "blue")
plot(temppopn, circles = 20, bg = "tan", fg = "white")
plot(temppopn, pch = 16, cex = 0.5, add = TRUE)
Usage

## S3 method for class 'secr'
plot(x, newdata = NULL, add = FALSE,
     sigmatick = FALSE, rgr = FALSE, limits = FALSE, alpha = 0.05,
     xval = 0:200, ylim = NULL, xlab = NULL, ylab = NULL, ...)

## S3 method for class 'secrlist'
plot(x, newdata = NULL, add = FALSE,
     sigmatick = FALSE, rgr = FALSE, limits = FALSE, alpha = 0.05,
     xval = 0:200, ylim = NULL, xlab = NULL, ylab = NULL, ...,
     overlay = TRUE)

detectfnplot (detectfn, pars, details = NULL, add = FALSE,
     sigmatick = FALSE, rgr = FALSE, hazard = FALSE, xval = 0:200, ylim = NULL,
     xlab = NULL, ylab = NULL, ...)

attenuationplot (pars, add = FALSE, spherical = TRUE,
     xval = 0:200, ylim = NULL, xlab = NULL, ylab = NULL, ...)

Arguments

- **x**: an secr object
- **newdata**: dataframe of data to form estimates
- **add**: logical to add curve(s) to an existing plot
- **sigmatick**: logical; if TRUE the scale parameter sigma is shown by a vertical line
- **rgr**: logical; if TRUE a scaled curve r.g(r) is plotted instead of g(r)
- **hazard**: logical; if TRUE the hazard of detection is plotted instead of probability
- **limits**: logical; if TRUE pointwise confidence limits are drawn
- **alpha**: alpha level for confidence intervals
- **xval**: vector of distances at for which detection to be plotted
- **ylim**: vector length 2 giving limits of y axis
- **xlab**: label for x axis
- **ylab**: label for y axis
- **...**: arguments to pass to lines
- **overlay**: logical; if TRUE then automatically add = TRUE for plots after the first
- **detectfn**: integer code or character string for shape of detection function 0 = halfnormal etc. – see detectfn
- **pars**: list, vector or matrix of parameter values
- **details**: list of ancillary parameters
- **spherical**: logical for whether to include spherical spreading term
plot.secr

Details

ewndata is usually NULL, in which case one curve is plotted for each session and group. Otherwise, predict.secr is used to form estimates and plot a curve for each row in newdata.

If axis labels are not provided they default to ‘Distance (m)’ and ‘Detection probability’ or ‘Detection lambda’.

detectfnplot is an alternative in which the user nominates the type of function and provides parameter values. pars maybe a list as from detectpar; it is first coerced to a numeric vector with unlist. Parameter values must be in the expected order (e.g. g0, sigma, z). If pars is a matrix then a separate curve is plotted with the parameter values in each row.

For detectfnplot the signal threshold parameters ‘cutval’ and ‘spherical’ should be provided in details (see examples).

Approximate confidence limits for g(r) are calculated using a numerical first-order delta-method approximation to the standard error at each xval. The distribution of g(r) is assumed to be normal on the logit scale for non-hazard functions (detectfn 0:13). For hazard detection functions (detectfn 14:18) the hazard is assumed (from version 3.1.1) to be distributed normally on the log scale. Limits are back-transformed to the probability scale g(r).

attenuationplot plots the expected decline in signal strength with distance, given parameters $\beta_0$ and $\beta_1$ for a log-linear model of sound attenuation.

Value

plot.secr invisibly returns a dataframe of the plotted values (or a list of dataframes in the case that newdata has more than one row).

See Also

Detection functions, plot, secr

Examples

plot (secr.demo.b, xval = 0:100, ylim = c(0, 0.4))
## Add recapture probability
plot (secr.demo.b, newdata = data.frame(b = 1), add = TRUE,
  col = "red")

## signal strength detection: 70dB at source, attenuation
## 0.3dB/m, sdS 5dB; detection threshold 40 dB.
detectfnplot (detectfn = 10, c(70, -0.3, 5), details =
  list(cutval = 40))

## add a function with louder source and spherical spreading...
detectfnplot (detectfn = 11, c(110, -0.3, 5), details =
  list(cutval = 40), add = TRUE, col = "red")

## matching sound attenuation curves; ‘spherical-only’ dashed line
attenuationplot (c(70, -0.3), spherical = FALSE, ylim=c(-10,110))
attenuationplot (c(110, 0), spherical = TRUE, add=TRUE, lty=2)
attenuationplot (c(110, -0.3), spherical = TRUE, add = TRUE,
col = "red")

plot.traps

Plot traps Object

Description

Map the locations of detectors (traps).

Usage

## S3 method for class 'traps'
plot(x, border = 100, label = FALSE, offset = c(6,6), add = FALSE,
     hidetr = FALSE, detpar = list(), txtpar = list(), bg = "white",
     gridlines = !add, gridspace = 100, gridcol = "grey",
     markused = FALSE, markvarying = FALSE, markvertices = FALSE,
     labelclusters = FALSE, frame = NULL, ...)

Arguments

x

a traps object

border

width of blank margin around the outermost detectors

label

logical indicating whether a text label should appear by each detector

offset

vector displacement of label from point on x and y axes

add

logical to add detectors to an existing plot

hidetr

logical to suppress plotting of detectors

detpar

list of named graphical parameters for detectors (passed to par)

txtpar

list of named graphical parameters for labels (passed to par)

bg

background colour

gridlines

logical for plotting grid lines

gridspace

spacing of gridlines

gridcol

colour of gridlines

markused

logical to distinguish detectors used on at least one occasion

markvarying

logical to distinguish detectors whose usage varies among occasions

markvertices

logical or 0,1,2 for plotting transect or polygon points

labelclusters

logical to label clusters

frame

data defining a boundary polygon (see boundarytoSF)

... arguments to pass to eqscplot
plotMaskEdge

Details

offset may also be a scalar value for equal displacement on the x and y axes. The hidetr option is most likely to be used when plot.traps is called by plot.capthist. See par and colours for more information on setting graphical parameters. The initial values of graphical parameters are restored on exit.

Axes are not labeled. Use axis and mtext if necessary.

markvertices determines whether the vertices of each transect or polygon will be emphasised by overplotting a point symbol (detpar$pch). Value may be logical (TRUE, FALSE) or integer (0 = no points, 1 = terminal vertices only, 2 = all vertices).

From 4.4.0, polygon detectors are shaded with detpar$col and outlined (border) with detpar$fg. Use detpar$col = NA for no shading (transparent polygons).

labelclusters requires x to have attributes 'clusterID' and 'clustertrap'.

A boundary polygon is plotted in black if frame is not NULL.

Value

None

See Also

plot, traps, clusterID

Examples

```r
temptrap <- make.grid()
plot (temptrap, detpar = list(pch = 16, col = "blue"),
     label = TRUE, offset = 7)
```

plotMaskEdge

Outline Around Mask Cells

Description

Plots the outer edge of a mask.

Usage

```r
plotMaskEdge(mask, plt = TRUE, add = FALSE, ...)
```

Arguments

- `mask`: secr habitat mask object
- `plt`: logical; if TRUE the edge is plotted
- `add`: logical; if TRUE the line is added to an existing plot
- `...`: other line plotting arguments passed to segments
pmixProfileLL

Description

Compute the profile likelihood of a finite mixture model for a user-specified range of values for the mixing parameter. This provides a check on multimodality.

Usage

pmixProfileLL(CH, model = list(g0 ~ h2, sigma ~ h2), CL = TRUE, pmvals = seq(0.01, 0.99, 0.01), pmi = 5, ...)

Arguments

CH capthist object
model model as in secr.fit
CL logical as in secr.fit
pmvals numeric vector of values for mixing parameter ‘pmix’
pointsInPolygon

pointsInPolygon

Description

Determines which of a set of points lie inside a closed polygon or at least one of a set of polygons.

Usage

pointsInPolygon(xy, poly, logical = TRUE)
## pointsInPolygon

### Arguments

- **xy**
  - 2-column matrix or dataframe of x-y coordinates for points to assess

- **poly**
  - 2-column matrix or dataframe containing perimeter points of polygon, or a SpatialPolygonsDataFrame object from package sp, or a ‘mask’ object (see Warning)

- **logical**
  - logical to control the output when ‘poly’ is a mask (see Details)

### Details

If `poly` is a SpatialPolygonsDataFrame object then the method `over` is used from sp. This allows multiple polygons and polygons with holes.

If `poly` is an secr ‘mask’ object then `xy` is discretized and matched to the cells in `poly`. If `logical` = FALSE then the returned value is a vector of integer indices to the row in `poly` corresponding to each row of `xy`; otherwise the result is a vector of logical values.

Otherwise, the algorithm is adapted from some code posted on the S-news list by Peter Perkins (23/7/1996). The polygon should be closed (last point same as first).

### Value

Vector of logical or integer values, one for each row in `xy`

### Warning

If `poly` is a mask object then its cells must be aligned to the x- and y- axes

### See Also

- `over`

### Examples

```r
## 100 random points in unit square
xy <- matrix(runif(200), ncol = 2)
## triangle centred on (0.5, 0.5)
poly <- data.frame(x = c(0.2,0.5,0.8,0.2), y = c(0.2,0.8,0.2,0.2))
plot(xy, pch = 1 + pointsInPolygon(xy, poly))
lines(poly)
```
polyarea

Description

Area of a single closed polygon (simple x-y coordinate input) or of multiple polygons, possibly with holes.

Usage

polyarea(xy, ha = TRUE)

Arguments

xy
dataframe or list with components ‘x’ and ‘y’, or a SpatialPolygons or SpatialPolygonsDataFrame object from package sp, or an sf object with polygon data

ha
logical if TRUE output is converted from square metres to hectares

Details

For sf, sfc, SpatialPolygons or SpatialPolygonsDataFrame objects, the package sf is used.

Value

A scalar.

See Also

buffer.contour

Examples

polyarea(make.grid(hollow = TRUE))

popn

Population Object

Description

Encapsulate the locations of a set of individual animals.
Details

An object of class `popn` records the locations of a set of individuals, together with ancillary data such as their sex. Often used for a realisation of a spatial point process (e.g. homogeneous Poisson) with known density (intensity). Locations are stored in a data frame with columns ‘x’ and ‘y’.

A `popn` object has attributes
possum

Description

Data from a trapping study of brushtail possums at Waitarere, North Island, New Zealand.

Usage

possumCH
possumarea
possumremovalarea
possummask
possum.model.0
possum.model.Ds

Details

Brushtail possums (*Trichosurus vulpecula*) are an unwanted invasive species in New Zealand. Although most abundant in forests, where they occasionally exceed densities of 15 / ha, possums live wherever there are palatable food plants and shelter.

Efford et al. (2005) reported a live-trapping study of possums in *Pinus radiata* plantation on coastal sand dunes. The 300-ha site at Waitarere in the North Island of New Zealand was a peninsula, bounded on one side by the sea and on two other sides by the Manawatu river. Cage traps were set in groups of 36 at 20-m spacing around the perimeter of five squares, each 180 m on a side. The squares (‘hollow grids’) were centred at random points within the 300-ha area. Animals were tagged and released daily for 5 days in April 2002. Subsequently, leg-hold trapping was conducted on a trapping web centred on each square (data not reported here), and strenuous efforts were made
to remove all possums by cyanide poisoning and further leghold trapping across the entire area. This yielded a density estimate of 2.26 possums / ha.

Traps could catch at most one animal per day. The live-trapped animals comprised 46 adult females, 33 adult males, 10 immature females and 11 immature males; sex and/or age were not recorded for 4 individuals (M. Coleman unpubl. data). These counts do not sum to the number of capture histories - see Note. One female possum was twice captured at two sites on one day, having entered a second trap after being released; one record in each pair was selected arbitrarily and discarded.

The data are provided as a single-session capthist object ‘possumCH’. ‘possummask’ is a matching mask object - see Examples. Two fitted models are provided for illustration.

The dataframe possumarea contains boundary coordinates of a habitat polygon that is used to clip possummask at the shore (from secr 1.5). possumarea comprises a single polygon representing the extent of terrestrial vegetation to the west, north and east, and an arbitrary straight southern boundary. The boundary is also included as a shapefile and as a text file (‘possumarea.shp’ etc. and ‘possumarea.txt’ in the package ‘extdata’ folder). See Examples in make.mask.

The dataframe possumremovalarea contains boundary coordinates of another polygon, the nominal removal area of Efford et al. (2005 Fig. 1) (from secr 2.3).

<table>

</tr>
</tbody>
</table>

Note

A significant problem with the data used by Efford et al. (2005) was noticed recently. Five capture histories in possumCH are for animals that had lost a previous tag. A further three histories may also have been animals that were tagged previously or mis-recorded. Analyses that treat each previously tagged animal as a new individual are in error (this includes the published analyses, the pre-fitted models described here, and those in the vignette secr-densitysurfaces.pdf). All eight questionable histories are now indicated in possumCH with the logical covariate ‘prev.tagged’.

Methods have not yet been developed to adjust for tag loss in SECR models.

## ...about 9%

## End(Not run)
```

### predict.secr

**SECR Model Predictions**

**Description**

Evaluate a spatially explicit capture–recapture model. That is, compute the ‘real’ parameters corresponding to the ‘beta’ parameters of a fitted model for arbitrary levels of any variables in the linear predictor.

**Usage**

```r
## S3 method for class 'secr'
predict(object, newdata = NULL, realnames = NULL, type = c("response", "link"),
   se.fit = TRUE, alpha = 0.05, savenew = FALSE, ...)
```
predict.secr

## S3 method for class 'secrlist'
predict(object, newdata = NULL, realnames = NULL, type = c("response", "link"),
        se.fit = TRUE, alpha = 0.05, savenew = FALSE, ...)

## S3 method for class 'secr'
detectpar(object, ..., byclass = FALSE)

### Arguments

- **object**: secr object output from secr.fit, or list of secr objects (secrlist)
- **newdata**: optional dataframe of values at which to evaluate model
- **realnames**: character vector of real parameter names
- **type**: character; type of prediction required. The default ("response") provides estimates of the ‘real’ parameters.
- **se.fit**: logical for whether output should include SE and confidence intervals
- **alpha**: alpha level for confidence intervals
- **savenew**: logical for whether newdata should be saved
- **...**: other arguments passed to `makeNewData`
- **byclass**: logical; if TRUE values are returned for each latent class in a mixture model, or class in a hybrid mixture (hcov) model

### Details

The variables in the various linear predictors are described in `secr-models.pdf` and listed for the particular model in the `vars` component of `object`.

Optional `newdata` should be a dataframe with a column for each of the variables in the model (see ‘vars’ component of `object`). If `newdata` is missing then a dataframe is constructed automatically.

Default `newdata` are for a naive animal on the first occasion; numeric covariates are set to zero and factor covariates to their base (first) level. From secr 3.1.4 the argument ‘all.levels’ may be passed to `newdata`; if TRUE then the default `newdata` includes all factor levels.

`realnames` may be used to select a subset of parameters.

Standard errors for parameters on the response (real) scale are by the delta method (Lebreton et al. 1992), and confidence intervals are backtransformed from the link scale.

The value of `newdata` is optionally saved as an attribute.

`detectpar` is used to extract the detection parameter estimates from a simple model to pass to functions such as `esa.plot`. `detectpar` calls `predict.secr`. Parameters will be evaluated by default at base levels of the covariates, although this may be overcome by passing a one-line `newdata` to `predict` via the ... argument. Groups and mixtures are a headache for `detectpar`: it merely returns the estimated detection parameters of the first group or mixture.

If the ‘a0’ parameterization has been used in `secr.fit` (i.e., `object$details$param == 3`) then `detectpar` automatically backtransforms (a0, sigma) to (g0, sigma) or (lambda0, sigma) depending on the value of `object$detectfn`. 
predict.secr

Value

When se.fit = FALSE, a dataframe identical to newdata except for the addition of one column for each ‘real’ parameter. Otherwise, a list with one component for each row in newdata. Each component is a dataframe with one row for each ‘real’ parameter (density, g0, sigma, b) and columns as below:

<table>
<thead>
<tr>
<th>link</th>
<th>link function</th>
</tr>
</thead>
<tbody>
<tr>
<td>estimate</td>
<td>estimate of real parameter</td>
</tr>
<tr>
<td>SE.estimate</td>
<td>standard error of the estimate</td>
</tr>
<tr>
<td>lcl</td>
<td>lower 100(1–alpha)% confidence limit</td>
</tr>
<tr>
<td>ucl</td>
<td>upper 100(1–alpha)% confidence limit</td>
</tr>
</tbody>
</table>

When newdata has only one row, the structure of the list is ‘dissolved’ and the return value is one data frame.

For detectpar, a list with the estimated values of detection parameters (e.g., g0 and sigma if detectfn = "halfnormal"). In the case of multi-session data the result is a list of lists (one list per session).

Note

predictDsurface should be used for predicting density at many points from a model with spatial variation. This deals automatically with scaling of x- and y-coordinates, and is much faster than predict.secr. The resulting Dsurface object has its own plot method.

The argument ‘scaled’ was removed from both predict methods in version 2.10 as the scaleg0 and scalesigma features had been superceded by other parameterisations.

Overdispersion results in confidence intervals that are too narrow. See adjustVarD for a partial solution.

Examples

```r
# load previously fitted secr model with trap response
# and extract estimates of ‘real’ parameters for both
# naive (b = 0) and previously captured (b = 1) animals
predict (secrdemo.b, newdata = data.frame(b = 0:1))
```
## OR from secr 3.1.4
predict (secrdemo.b, all.levels = TRUE)

temp <- predict (secrdemo.b, all.levels = TRUE, save = TRUE)
attr(temp, "newdata")
detectpar(secrdemo.0)

---

### predictDsurface

**Predict Density Surface**

#### Description
Predict density at each point on a raster mask from a fitted secr model.

#### Usage

```
predictDsurface(object, mask = NULL, se.D = FALSE, cl.D = FALSE, alpha = 0.05, parameter = c('D', 'noneuc'))
```

#### Arguments

- **object**: fitted secr object
- **mask**: secr mask object
- **se.D**: logical for whether to compute prediction SE
- **cl.D**: logical for whether to compute confidence limits
- **alpha**: alpha level for 100(1 – alpha)% confidence intervals
- **parameter**: character for real parameter to predict

#### Details
Predictions use the linear model for density on the link scale in the fitted secr model ‘object’, or the fitted user-defined function, if that was specified in `secr.fit`.

If ‘mask’ is NULL then predictions are for the mask component of ‘object’.

SE and confidence limits are computed only if specifically requested. They are not available for user-defined density functions.

Density is adjusted automatically for the number of clusters in ‘mashed’ models (see `mash`).

#### Value
Object of class ‘Dsurface’ inheriting from ‘mask’. Predicted densities are added to the covariate data frame (attribute ‘covariates’) as column(s) with prefix ‘D.’ If the model uses multiple groups, multiple columns will be distinguished by the group name (e.g., “D.F” and “D.M”). If groups are not defined the column is named “D.0”.

For multi-session models the value is a multi-session mask.

The pointwise prediction SE is saved as a covariate column prefixed ‘SE.’ (or multiple columns if multiple groups). Confidence limits are likewise saved with prefixes ‘lcl.’ and ‘ucl.’.

pm <- plot(regionPossums, plottype = "persp", box = FALSE, zlim = c(0,3), phi=30, d = 5, col = "green", shade = 0.75, border = NA)
lines(trans3d(possumremovalarea$x, possumremovalarea$y, rep(1,nrow(possumremovalarea)), pmat = pm))
```

```r
par(mfrow = c(1,1), mar = c(5, 4, 4, 2) + 0.1) ## reset to default
```

```r
## compare estimates of region N
## grid cell area is 0.01 ha
sum(covariates(regionPossums)[,"D.0"] * 0.01
region.N(possum.model.Ds, regionmask)
```

```r
## End(Not run)
```

### print.capthist

**Print Detections**

**Description**

Print method for `capthist` objects.

**Usage**

```r
## S3 method for class 'capthist'
print(x, ..., condense = FALSE, sortrows = FALSE)
```

**Arguments**

- `x` : capthist object
- `...` : arguments to pass to `print.default`
- `condense` : logical, if true then use condensed format for 3-D data
- `sortrows` : logical, if true then sort output by animal

**Details**

The `condense` option may be used to format data from proximity detectors in a slightly more readable form. Each row then presents the detections of an individual in a particular trap, dropping rows (traps) at which the particular animal was not detected.

**Value**

Invisibly returns a dataframe (`condense = TRUE`) or array in the format printed.
### print.secr

Print results from fitting a spatially explicit capture–recapture model or generate a list of summary values.

#### Usage

```r
# S3 method for class 'secr'
print(x, newdata = NULL, alpha = 0.05, deriv = FALSE, call = TRUE, ...)
# S3 method for class 'secr'
summary(object, newdata = NULL, alpha = 0.05, deriv = FALSE, ...)
```

#### Arguments

- `x`: secr object output from `secr.fit`
- `object`: secr object output from `secr.fit`
- `newdata`: optional dataframe of values at which to evaluate model
- `alpha`: alpha level
- `deriv`: logical for calculation of derived D and esa
- `call`: logical; if TRUE the call is printed
- `...`: other arguments optionally passed to `derived.secr`

#### Details

Results from `print.secr` are potentially complex and depend upon the analysis (see below). Optional `newdata` should be a dataframe with a column for each of the variables in the model. If `newdata` is missing then a dataframe is constructed automatically. Default `newdata` are for a naive animal on the first occasion; numeric covariates are set to zero and factor covariates to their base (first) level. Confidence intervals are 100 (1 – alpha) % intervals.

- `call`: the function call (optional)
- `version, time`: secr version, date and time fitting started, and elapsed time
- `Detector type`: ‘single’, ‘multi’, ‘proximity’ etc.
- `Detector number`: number of detectors
Average spacing
x-range
y-range
New detector type as fitted when details$newdetector specified
N animals number of distinct animals detected
N detections number of detections
N occasions number of sampling occasions
Mask area
Model model formula for each ‘real’ parameter
Fixed (real) fixed real parameters
Detection fn detection function type (halfnormal or hazard-rate)
N parameters number of parameters estimated
Log likelihood log likelihood
AIC Akaike’s information criterion
AICc AIC with small sample adjustment (Burnham and Anderson 2002)
Beta parameters coef of the fitted model, SE and confidence intervals
vcov variance-covariance matrix of beta parameters
Real parameters fitted (real) parameters evaluated at base levels of covariates
Derived parameters derived estimates of density and mean effective sampling area (optional)

Derived parameters (see derived) are computed only if deriv = TRUE.

Value
The summary method constructs a list of outputs similar to those printed by the print method, but somewhat more concise and re-usable:

versiontime secr version, and date and time fitting started
traps detector summary
capthist capthist summary
mask mask summary
modeldetails miscellaneous model characteristics (CL etc.)
AICtable single-line output of AIC.secr
coef table of fitted coefficients with CI
predicted predicted values (‘real’ parameter estimates)
derived output of derived.secr (optional)

**print.traps**  
*Print Detectors*

**Description**

Print method for traps objects.

**Usage**

```r
## S3 method for class 'traps'
print(x, ...)
```

**Arguments**

- `x` traps object
- `...` arguments to pass to `print.default`

**See Also**

`print.traps`

**Examples**

```r
print(make.grid(nx = 5, ny = 3))
```
randomHabitat

**Description**

The Modified Random Cluster algorithm of Saura and Martinez-Millan (2000) is used to generate a mask object representing patches of contiguous ‘habitat’ cells (pixels) within a ‘non-habitat’ matrix (‘non-habitat’ cells are optionally dropped). Spatial autocorrelation (fragmentation) of habitat patches is controlled via the parameter ‘p’. ‘A’ is the expected proportion of ‘habitat’ cells.

`randomDensity` is a wrapper for `randomHabitat` that may be used as input to `sim.popn`.

**Usage**

```r
code
randomHabitat(mask, p = 0.5, A = 0.5, directions = 4, minpatch = 1, drop = TRUE, covname = "habitat", plt = FALSE, seed = NULL)

randomDensity(mask, parm)
```

**Arguments**

- `mask`: secr mask object to use as template
- `p`: parameter to control fragmentation
- `A`: parameter for expected proportion of habitat
- `directions`: integer code for adjacency (rook’s move 4 or queen’s move 8)
- `minpatch`: integer minimum size of patch
- `drop`: logical for whether to drop non-habitat cells
- `covname`: character name of covariate when `drop = FALSE`
- `plt`: logical for whether intermediate stages should be plotted
- `seed`: either NULL or an integer that will be used in a call to `set.seed`
- `parm`: list of arguments for `randomHabitat`, with added argument D

**Details**

Habitat is simulated within the region defined by the cells of `mask`. The region may be non-rectangular.

The algorithm comprises stages A-D:

A. Randomly select proportion p of cells from the input mask
B. Cluster selected cells with any immediate neighbours as defined by `directions`
C. Assign clusters to ‘non-habitat’ (probability 1–A) and ‘habitat’ (probability A)
D. Cells not in any cluster from (B) receive the habitat class of the majority of the <=8 adjacent cells assigned in (C), if there are any; otherwise they are assigned at random (with probabilities 1–A, A).
Fragmentation declines, and cluster size increases, as p increases up to the ‘percolation threshold’ which is about 0.59 in the default case (Saura and Martinez-Millan 2000 p.664).

If minpatch > 1 then habitat patches of less than minpatch cells are converted to non-habitat, and vice versa. This is likely to cause the proportion of habitat to deviate from A.

If drop = FALSE a binary-valued (0/1) covariate with the requested name is included in the output mask, which has the same extent as the input. Otherwise, non-habitat cells are dropped and no covariate is added.

The argument ‘parm’ for randomDensity is a list with average density D and an optional subset of named values to override the defaults (p = 0.5, A = 0.5, directions = 4, minpatch = 1, plt = FALSE, seed = NULL). ‘rescale’ is a further optional component of ‘parm’; if ‘rescale = TRUE’ then the pixel-specific densities are adjusted upwards by the factor 1/A to maintain the same expected number of activity centres as if the nominal density applied throughout. Arguments ‘mask’ and ‘drop’ of randomHabitat are substituted automatically.

Value

For randomHabitat –

An object of class ‘mask’. By default (drop = TRUE) this has fewer rows (points) than the input mask.

The attribute “type” is a character string formed from paste(‘MRC p=’,p,’ A=’,A, sep=’ ’).

The RNG seed is stored as attribute ‘seed’ (see secrRNG).

For randomDensity –

A vector of cell-specific densities.

Note

Single-linkage clustering and adjacency operations use functions ‘clump’ and ‘adjacency’ of the package raster; ‘clump’ also requires package igraph0 (raster still uses this deprecated version). Optional plotting of intermediate stages (plt = TRUE) uses the plot method for rasterLayers in raster.

A non-rectangular input mask is padded out to a rectangular rasterLayer for operations in raster; cells added as padding are ultimately dropped.

The procedure of Saura and Martinez-Millan (2000) has been followed as far as possible, but this implementation may not match theirs in every detail.

This implementation allows only two habitat classes. The parameter A is the expected value of the habitat proportion; the realised habitat proportion may differ quite strongly from A, especially for large p (e.g., p > 0.5).

Anisotropy is not implemented; it would require skewed adjacency filters (i.e. other than rook- or queen-move filters) that are not available in raster.

Gaussian random fields provide an alternative method for simulating random habitats (e.g., rLGCP option in sim.popn).

plot(mrcmask, dots = FALSE, col = "green")
mrcmask <- randomHabitat(tempmask, p = 0.4, A = 0.4, minpatch = 5)
plot(mrcmask, dots = FALSE, col = "green")
par(opar)

## End(Not run)
Create a RasterLayer Object from Mask or Dsurface

Description

Methods to convert secr object to a RasterLayer object.

Usage

```r
## S4 method for signature 'mask'
raster(x, covariate, values = 1, crs = NA)

## S4 method for signature 'Dsurface'
raster(x, covariate, values = 1, crs = NA)

## S4 method for signature 'mask'
rast(x, covariate, values = 1, crs = "")

## S4 method for signature 'Dsurface'
rast(x, covariate, values = 1, crs = "")
```

Arguments

- `x`: mask or Dsurface object
- `covariate`: character name of covariate to provide values for RasterLayer
- `values`: numeric values for RasterLayer
- `crs`: character or object of class CRS. Optional PROJ.4 type description of a Coordinate Reference System (map projection).

Details

There are two ways to specify the values to be used. If `covariate` is provided then the values of the corresponding covariate of the mask or Dsurface are used. Otherwise, values is duplicated to the required number of rows.

The resulting RasterLayer may optionally include a PROJ.4 map projection defined via `crs`. The specification may be very simple (as in the example below) or complex, including an explicit datum and other arguments. Projections are used by `sf`, `terra`, `raster`, `sp` and other packages. See `raster` for further explanation and links.

The S3 classes ‘mask’ and ‘Dsurface’ are defined in secr as virtual S4 classes. This enables these extensions to the list of S4 methods defined in raster.

Although these methods work ‘standalone’, it is currently necessary to load the terra or raster package to do much with the result (e.g., plot it).
**Value**

RasterLayer (raster)

**Note**

Prior to secr 2.9.5 these methods could fail unpredictably because an intermediate array was badly dimensioned due to truncation of a floating point value.

**See Also**

raster

**Examples**

```r
## Not run:
shorePossums <- predictDsurface(possum.model.Ds)
tmp <- raster(shorePossums, covariate = "D.0")
library(raster)
plot(tmp, useRaster = FALSE)

## alternative with same result
tmp <- raster(shorePossums, values = covariates(shorePossums)$D.0)

## set the projection
## here the crs PROJ.4 spec refers simply to the old NZ metric grid
tmp <- raster(shorePossums, "D.0", crs = "+proj=nzmg")
## check the projection
proj4string(tmp)

## End(Not run)
```

---

**rbind.capthist**

*Combine capthist Objects*

**Description**

Form a single capthist object from two or more compatible capthist objects.

**Usage**

```r
MS.capthist(...)

## S3 method for class 'capthist'
rbind(..., renumber = TRUE, pool = NULL, verify = TRUE)
```
Arguments

... one or more capthist objects or lists of capthist objects
renumber logical, if TRUE assigns new composite individual ID
pool list of vectors of session indices or names
verify logical, if TRUE the output is checked with verify

Details

MS.capthist concatenates the sessions in the input objects as one multi-session capthist object. Each session may use a different detector array (traps) and a different number of sampling occasions. Session names are derived implicitly from the inputs, or may be given explicitly (see Examples); if any name is duplicated, all will be replaced with sequential integers. The ...argument may include lists of single-session capthist objects.

The rbind method for capthist objects is used to pool capture data from more than one session into a single session. The number of rows in the output session is the sum of the number of rows in the input sessions (i.e. each animal appears in only one session). Sessions to be pooled with rbind must have the same number of capture occasions and use the same detectors (traps). At present there is no function to pool capthist data from different detector arrays. For this it is recommended that you merge the input files and rebuild the capthist object from scratch.

For rbind.capthist, the ...argument may be

1. A series of single-session capthist objects, which are pooled to form one new single-session object, or
2. One multi-session capthist object, when the components of ‘pool’ are used to define combinations of old sessions; e.g. pool = list(A=1:3, B=4:5) produces an object with two sessions (named ‘A’ and ‘B’) from 5 old ones. If pool = NULL (the default) then all the sessions are pooled to form one single-session capthist object.

The names of arguments other than ...should be given in full. If renumber = TRUE (the default), the session name will be prepended to the animal ID before pooling: animals 1, 2 and 3 in Session A will become A.1, A.2 and A.3, while those in Session B become B.1, B.2 and B.3. This ensures that each animal has a unique ID. If renumber = FALSE, the animal IDs will not change.

Other attributes (xy, signal) are handled appropriately. If the signal threshold (attribute ‘cutval’) differs among sessions, the maximum is used and detections of lower signal strength are discarded.

The use of rbind.capthist to concatenate sessions is now deprecated: use MS.capthist.

Although MS.capthist looks like an S3 method, it isn’t. The full function name must be used. rbind.capthist became an S3 method in secr 3.1, so it is called as rbind alone.

Value

For MS.capthist, a multi-session object of class ‘capthist’ with number of sessions equal to the number of sessions in the objects in ....

For rbind.capthist, either an object of class ‘capthist’ with one session formed by pooling the sessions in the input objects, or a capthist object with more than one session, each formed by pooling groups of sessions defined by the ‘pool’ argument. Covariate columns that appear in all input sessions are retained in the output.
See Also

capthist, subset.capthist

Examples

```r
## extend a multi-session object
## we fake the 2010 data by copying from 2005
## note how we name the appended session
fakeCH <- ovenCH[["2005"]]
MS.capthist(ovenCH, "2010" = fakeCH)

## simulate sessions for 2-part mixture
temprep <- make.grid(nx = 8, ny = 8)
temp1 <- sim.capthist(temptrap,
  detectpar = list(g0 = 0.1, sigma = 40))
temp2 <- sim.capthist(temptrap,
  detectpar = list(g0 = 0.2, sigma = 20))

## concatenate sessions
temp3 <- MS.capthist(large.range = temp1, small.range = temp2)
summary(temp3)
## session-specific movement statistic
RPSV(temp3)

## pool sessions
temp4 <- rbind(temp1, temp2)
summary(temp4)

## compare mixture to sum of components
## note 'detectors visited' is not additive for 'multi' detector
## nor is 'detectors used'
(summary(temp1)$counts + summary(temp2)$counts) -
  summary(temp4)$counts

## Not run:

## compare two different model fits
tempfit3 <- secr.fit(temp3, CL = TRUE, buffer = 150, model = list
  (g0 ~ session, sigma ~ session), trace = FALSE)
predict(tempfit3)

## if we can tell which animals had large ranges...
covariates(temp4) <- data.frame(range.size = rep(c("large",
  "small"), c(nrow(temp1), nrow(temp2))))
tempfit4 <- secr.fit(temp4, CL = TRUE, buffer = 150, model = list
  (g0 ~ range.size, sigma ~ range.size), trace = FALSE)
predict(tempfit4, newdata = data.frame(range.size = c("large",
  "small")))

## polygon data
```
pol1 <- make.poly()
pol2 <- make.poly(x = c(50,50,150,150))
ch1 <- sim.capthist(pol1, popn = list(D = 30), detectfn = 'HHN',
                  detectpar = list(lambda0 = 0.3))
ch2 <- sim.capthist(pol2, popn = list(D = 30), detectfn = 'HHN',
                  detectpar = list(lambda0 = 0.3))
plot(ch1); plot(pol2, add = TRUE); plot(ch2, add = TRUE)

## End(Not run)

---

**rbind.popn**

**Combine popn Objects**

**Description**

Form a single **popn** object from two or more existing **popn** objects, or a list.

**Usage**

```r
## S3 method for class 'popn'
rbind(..., renumber = TRUE)
```

**Arguments**

- `...` one or more **popn** objects
- `renumber` logical for whether row names in the new object should be set to the row indices

**Details**

An attempt to combine objects will fail if they conflict in their covariates attributes.

From **secr** 3.1 this is an S3 method and list input is not allowed.

**Value**

An object of class **popn** with number of rows equal to the sum of the rows in the input objects.

**See Also**

- **popn**
Examples

```r
## generate and combine two subpopulations
trapobj <- make.grid()
p1 <- sim.popn(D = 3, core = trapobj)
p2 <- sim.popn(D = 2, core = trapobj)
covariates(p1) <- data.frame(size = rep("small", nrow(p1)))
covariates(p2) <- data.frame(size = rep("large", nrow(p2)))
pop <- rbind(p1, p2)

## or
pop <- do.call(rbind, list(p1, p2))
```

---

**rrbind.traps**

**Combine traps Objects**

**Description**

Form a single `traps` object from two or more existing `traps` objects.

**Usage**

```r
## S3 method for class 'traps'
rrbind(..., renumber = TRUE, addusage, checkdetector = TRUE, suffix = TRUE)
```

**Arguments**

- `...`: one or more `traps` objects
- `renumber`: logical for whether row names in the new object should be set to the row indices
- `addusage`: integer vector; if specified and the inputs lack usage attributes then a binary usage attribute will be generated with the given number of occasions for each input
- `checkdetector`: logical; if TRUE then variation in the detector attribute triggers a warning
- `suffix`: logical; if TRUE then suffix to the row names indicates source

**Details**

An attempt to combine objects will fail if they conflict in their covariates attributes. Differences in the usage attribute are handled as follows. If usage is missing for all inputs and addusage = TRUE is specified then usage codes are generated automatically (positive for the specified number of occasions). If usage is specified for one input but not other(s), the missing values are constructed assuming all detectors were operated for the maximum number of occasions in any input. If inputs differ in the number of ‘usage’ columns (occasions), the smaller matrices are padded with ‘zero’ columns to the maximum number of columns in any input.

... may be a single multi-session `traps` object (from 2.10.0).
By default (and always prior to 3.1.1) row names include a suffix (e.g., ".1", or ".2") to indicate the original object (first, second etc.). A suffix is added automatically to all names if any name is duplicated, and a warning is generated.

Value

An object of class traps with number of rows equal to the sum of the rows in the input objects.

See Also

traps, subset.traps

Examples

```r
## nested hollow grids
hollow1 <- make.grid(nx = 8, ny = 8, hollow = TRUE)
hollow2 <- shift(make.grid(nx = 6, ny = 6, hollow = TRUE),
                 c(20, 20))
nested <- rbind(hollow1, hollow2)
plot(nested, gridlines = FALSE, label = TRUE)
```

Description

Data in the DENSITY formats for capture data and trap layouts may be imported as a capthist object for analysis in secr. Data in a capthist object may also be exported in these formats for use in DENSITY (Efford 2012). read.capthist inputs data from text files and constructs a capthist object in one step using the functions read.traps and make.capthist. Data may also be read from Excel spreadsheets if the package readxl is installed (see secr-datainput.pdf).

Usage

```r
read.capthist(captfile, trapfile, detector = "multi", fmt = c("trapID","XY"),
              noccasions = NULL, covnames = NULL, trapcovnames = NULL,
              cutval = NULL, verify = TRUE, noncapt = "NONE", tol = 0.01, snapXY = FALSE,
              markocc = NULL, ...)

write.capthist(object, filestem = deparse(substitute(object)),
                sess = "1", ndec = 2, covariates = FALSE, tonumberic = TRUE, ...)
```
Arguments

- **captfile**: name of capture data file
- **trapfile**: name of trap layout file or (for a multi-session captfile) a vector of file names, one for each session
- **detector**: character value for detector type (‘single’, ‘multi’, ‘proximity’, etc.)
- **fmt**: character value for capture format (‘trapID’ or ‘XY’)
- **noccasions**: number of occasions on which detectors were operated
- **covnames**: character vector of names for individual covariate fields in ‘captfile’
- **trapcovnames**: character vector of names for detector covariate fields in ‘trapfile’
- **cutval**: numeric, threshold of signal strength for ‘signal’ detector type
- **verify**: logical if TRUE then the resulting capthist object is checked with verify
- **noncapt**: character value; animal ID used for ‘no captures’
- **tol**: numeric, snap tolerance in metres
- **snapXY**: logical; if TRUE then fmt = ‘XY’ uses nearest trap within tol
- **markocc**: integer vector distinguishing marking occasions (1) from sighting occasions (0)
- **object**: capthist object with the captures and trap locations to export
- **filestem**: character value used to form names of output files
- **sess**: character session identifier
- **ndec**: number of digits after decimal point for x,y coordinates
- **covariates**: logical or a character vector of covariates to export
- **tonumeric**: logical for whether factor and character covariates should be converted to numeric values on output

Details

**read.capthist**

captfile should record one detection on each line. A detection comprises a session identifier, animal identifier, occasion number (1, 2,...,S where S is the number of occasions), and a detector identifier (fmt = "trapID") or X- and Y-coordinates (fmt = "XY"). Each line of trapfile has a detector identifier and its X- and Y-coordinates. In either file type the identifiers (labels) may be numeric or alphanumeric values. Values should be separated by blanks or tabs unless (i) the file name ends in ‘.csv’ or (ii) sep = "," is passed in ..., in which case commas are assumed. Blank lines and any text after ‘#’ are ignored. For further details see secr-datainput.pdf, make.capthist and ‘Data formats’ in the help for DENSITY.

The noccasions argument is needed only if there were no detections on the final occasion; it may be a positive integer (constant across all sessions) or a vector of positive integers, one for each session. covnames is needed only when captfile includes individual covariates. Likewise for trapcovnames and detector covariates. Values of noccasions and covnames are passed directly to make.capthist, and trapcovnames is passed to read.traps.

A session identifier is required even for single-session capture data. In the case of data from multiple sessions, trapfile may be a vector of file names, one for each session.
Additional data may be coded as for DENSITY. Specifically, captfile may include extra columns of individual covariates, and trapfile may code varying usage of each detector over occasions and detector covariates.

markocc is needed only if sightings of unmarked animals are potentially recorded on some occasions. If the data span multiple sessions with differing combinations of marking and sighting occasions then markocc may be a list with one vector per session.

The function read.telemetry is a simplified version of read.capthist for telemetry data.

write.capthist

For a single-session analysis, DENSITY requires one text file of capture data and one text file with detector coordinates (the ‘trap layout’ file). write.capthist constructs names for these files by appending ‘capt.txt’ and ‘trap.txt’ to filestem which defaults to the name of the capthist object. If filestem is empty then output goes to the console.

If object contains multiple sessions with differing traps then a separate trap layout file is exported for each session and each file name includes the session name. All capture data are exported to one file regardless of the number of sessions. The DENSITY format used is ‘TrapID’ except when x-y coordinates are specific to a detection (i.e., polygon and transect detectors).

covariates controls the export of both detector and individual covariates. If it is TRUE or FALSE then it is taken to apply to both. A vector of covariate names is used as a lookup for both detector and capthist covariate fields: covariates are exported if their name matches; this may be used to export any combination of (uniquely named) detector and capthist covariates.

Existing text files will be replaced without warning. In the case of a multi-session capthist file, session names are taken from object rather than sess. Session names are truncated to 17 characters with blanks and commas removed.

To export data in comma-delimited (‘.csv’) format, pass sep = "," in .... The resulting files have extension ‘.csv’ rather than ‘.txt’ and may be opened with spreadsheet software.

Note

The original DENSITY formats accommodate ‘single’, ‘multi’ and ‘proximity’ data. Data for the newer detector types (‘count’, ‘signal’, ‘polygon’, ‘polygonX’, ‘transect’, ‘transectX’ and ‘telemetryonly’) may be input using the DENSITY formats with minor variations. They may also be output with write.capthist, but a warning is given that DENSITY does not understand these data types. See detector and secr-datainput.pdf for more.

The … argument is useful for some special cases. For example, if your input uses ‘;’ instead of ‘#’ for comments (‘;’ is also valid in DENSITY) then set comment.char = ";" in read.capthist.

In a similar fashion, write comma- or tab-separated values by setting sep = "", or sep = "\t" respectively.

The arguments of count.fields are a subset of those of read.table so ...is limited to any of {sep, quote, skip, blank.lines.skip, comment.char}.

If you fail to set fmt correctly in read.capthist then the error message from verify may be uninformative.

Examples

## export ovenbird capture histories
## the files "ovenCHcapt.txt" and "ovenCHtrap.txt" are
## placed in the current folder (check with getwd() or dir())

## Not run:
write.capthist(ovenCH)

## End(Not run)

---

read.mask Read Habitat Mask From File

Description

Read coordinates of points on a habitat mask from a text file.

Usage

read.mask(file = NULL, data = NULL, spacing = NULL, columns = NULL, ...)

Arguments

- file character string with name of text file
- data dataframe
- spacing spacing of grid points in metres
- columns character vector naming the columns to save as covariates
- ... other arguments to pass to read.table
Details

For file input, the x and y coordinates are usually the first two values on each line, separated by white space. If the file starts with a line of column headers and ‘header = TRUE’ is passed to `read.table` in the …argument then ‘x’ and ‘y’ need not be the first two fields.

data is an alternative input route if the x and y coordinates already exist in R as columns in a dataframe. Only one of data or file should be specified.

The grid cell size `spacing` should be provided if known. If it is not provided then an attempt is made to infer it from the minimum spacing of points. This can be slow and may demand more memory than is available. In rare cases (highly fragmented masks) it may also yield the wrong answer.

From 2.3.0, additional columns in the input are saved as covariates. The default (`columns = NULL`) is to save all columns.

Value

object of class `mask` with type ‘user’

Note

`read.mask` creates a single-session mask. If used in `secr.fit` with a multi-session capthist object a single-session mask will be replicated to the number of sessions. This is appropriate if all sessions relate to the same geographical region. If the ‘sessions’ relate to different regions you will need to construct a multi-session mask as a list of single-session masks (e.g. `mask <- list(mask1, mask2, mask3)`).

See Also

`mask`

Examples

```r
## Replace file name with a valid local name and remove `"`#
# read.mask (file = "c:\myfolder\mask.txt",
# spacing = 3, header = TRUE)
## "mask.txt" should have lines like this
## x y
## 265 265
## 268 265
## ...
```

---

**read.telemetry**

*Import Telemetry Fixes*

**Description**

A shortcut function for constructing a telemetry capthist object from a file of telemetry fixes. Telemetry data are generally similar in format to polygon data (see also `addTelemetry`).
read.telemetry

Usage

read.telemetry(file = NULL, data = NULL, covnames = NULL, verify = TRUE, ...)

Arguments

file character name of text file
data data.frame containing coordinate data (alternative to file)
covnames character vector of names for individual covariates
verify logical for whether to check input
... other arguments passed to countfields, read.table etc.

Details

Input data may be in a text file (argument file) or a dataframe (argument data). Data should be in the XY format for function ‘read.capthist’ i.e. the first 5 columns should be Session, ID, Occasion, X, Y. Further columns are treated as individual covariates.

No ‘traps’ input is required. A traps object is generated automatically.

Value

An secr capthist object including attribute ‘telemetryxy’ with the x-y coordinates, and a ‘traps’ object with detector type = ‘telemetry’

See Also

addTelemetry, read.capthist

Examples

## Not run:
olddir <- setwd("D:/bears/alberta")
## peek at raw data
head(readLines("gps2008.txt"))
gps2008CH <- read.telemetry("gps2008.txt")
setwd(olddir)

plot( gps2008CH, gridsp = 10000)
head(gps2008CH)
secr.fit(gps2008CH, start = log(4000), detectfn = 'HHN',
      details = list(telemetryscale = 1e12))

## End(Not run)
Description

Construct an object of class `traps` with detector locations from a text file or data frame. Usage per occasion and covariates may be included. Data may also be read from an Excel spreadsheet (see `secr-datainput.pdf`).

Usage

```r
read.traps(file = NULL, data = NULL, detector = "multi", covnames = NULL, binary.usage = TRUE, markocc = NULL, trapID = NULL, ...)```

Arguments

- `file` character string with name of text file
- `data` data frame of detector coordinates
- `detector` character string for detector type
- `covnames` character vector of names for detector covariate fields
- `binary.usage` logical; if FALSE will read usage fields as continuous effort
- `markocc` integer vector distinguishing marking occasions (1) from sighting occasions (0)
- `trapID` character column containing detector names (see Details)
- `...` other arguments to pass to `read.table`

Details

Reads a text file in which the first column is a character string (see Note) identifying a detector and the next two columns are its x- and y-coordinates, separated by white space. The coordinates optionally may be followed by a string of codes ‘0’ or ‘1’ indicating whether the detector was operated on each occasion. Trap-specific covariates may be added at the end of the line preceded by ‘/’. This format is compatible with the Density software (Efford 2012), except that all detectors are assumed to be of the same type (usage codes greater than 1 are treated as 1), and more than one covariate may be specified.

If `file` is missing then x-y coordinates will be taken instead from `data`, which should include columns ‘x’ and ‘y’. Row names of `data` are read as detector identifiers unless `trapID` is specified. This option does not allow for covariates or usage, but they may be added later.

detector specifies the behaviour of the detector following Efford et al. (2009). ‘single’ refers to a trap that is able to catch at most one animal at a time; ‘multi’ refers to a trap that may catch more than one animal at a time. For both ‘single’ and ‘multi’ detectors a trapped animals can appear at only one detector per occasion. Detectors of type ‘proximity’, such as camera traps and hair snags for DNA sampling, allow animals to be recorded at several detectors on one occasion. See `detector` for further detector types.
For polygon and transect detector types, each line corresponds to a vertex and starts with a code to identify the polygon or transect (hence the same code appears on 2 or more lines). For input from a dataframe the code column should be named ‘polyID’. Also, usage and covariates are for the polygon or transect as a whole and not for each vertex. Usage and covariates are appended to the end of the line, just as for point detectors (traps etc.). The usage and covariates for each polygon or transect are taken from its first vertex. Although the end-of-line strings of other vertices are not used, they cannot be blank and should use the same spacing as the first vertex.

_value_

An object of class `traps` comprising a data frame of x- and y-coordinates, the detector type (‘single’, ‘multi’, ‘proximity’, ‘count’, ‘polygon’ etc.), and possibly other attributes.

**Note**

Detector names, which become row names in the traps object, should not contain underscores.

Prior to 4.3.1 the function did not read usage or covariates from xls or data input.

**References**

**See Also**

`traps`, `make.grid`, `detector`

**Examples**

```r
## Not run:  # in following, replace file name with a valid local name
dataframe <- paste0(system.file("extdata", package = "secr"), "/trap.txt'
tr <- read.traps (filename, detector = "proximity")
summary(tr)

# Or if we have a dataframe of coordinates...
mytr <- data.frame(x = c(365,365,365), y = c(365,395,425))
row.names = c('A','B','C'))
mytr
```

## 204
rectangularMask

Description

Convert a mask or Dsurface with an irregular outline into a mask or Dsurface with a rectangular outline and the same bounding box. This enables contour plotting.

Usage

rectangularMask(mask)

Arguments

mask  
object of class mask or Dsurface

Details

The covariates of new points are set to missing. The operation may be reversed (nearly) with subset(rectmask, attr(rectmask, "OK")).

The results are unpredictable if the mask has been rotated.

Value

A rectangular mask or Dsurface with the same ‘area’, ‘boundingbox’, ‘meanSD’, ‘polygon’ and ‘polygon.habitat’ attributes as mask. A logical vector attribute ‘OK’ is added identifying the points inherited from mask.

See Also

plot.Dsurface

Examples

rMask <- rectangularMask(possummask)
plot(rMask)
plot(possummask, add = TRUE, col = "blue")
Description
Combine columns in a matrix-like object to create a new data set using the first non-zero value.

Usage

reduce(object, ...)
# Default S3 method:
reduce(object, columns, ...)

Arguments

object  object that may be coerced to a matrix
columns list in which each component is a vector of subscripts for columns to be pooled
...     other arguments (not used currently)

Details
The first element of columns defines the columns of object for the first new column, the second for the second new column etc. This is a generic method. More useful methods exist for capthist and traps objects.

Value
A matrix with number of columns equal to length(columns).

See Also
capthist, reduce.capthist, reduce.traps

Examples

## matrix with random zeros
temp <- matrix(runif(20), nc = 4)
temp[sample(20,10)] <- 0
temp

reduce(temp, list(1:2, 3:4))
**reduce.capthist**  
*Combine Occasions Or Detectors*

---

**Description**

Use these methods to combine data from multiple occasions or multiple detectors in a capthist or traps object, creating a new data set and possibly converting between detector types.

**Usage**

```r
## S3 method for class 'traps'
reduce(object, newtraps = NULL, newoccasions = NULL, span = NULL,
       rename = FALSE, newxy = c('mean', 'first'), ...)

## S3 method for class 'capthist'
reduce(object, newtraps = NULL, span = NULL, rename =
       FALSE, newoccasions = NULL, by = 1, outputdetector = NULL,
       select = c("last","first","random"), dropunused = TRUE, verify
       = TRUE, sessions = NULL, ...)
```

**Arguments**

- **object**: traps or capthist object
- **newtraps**: list in which each component is a vector of subscripts for detectors to be pooled
- **newoccasions**: list in which each component is a vector of subscripts for occasions to be pooled
- **span**: numeric maximum span in metres of new detector
- **rename**: logical; if TRUE the new detectors will be numbered from 1, otherwise a name will be constructed from the old detector names
- **newxy**: character; coordinates when detectors grouped with ‘newtraps’
- **by**: number of old occasions in each new occasion
- **outputdetector**: character value giving detector type for output (defaults to input)
- **select**: character value for method to resolve conflicts
- **dropunused**: logical, if TRUE any never-used detectors are dropped
- **verify**: logical, if TRUE the verify function is applied to the output
- **sessions**: vector of session indices or names (optional)
- **...**: other arguments passed by reduce.capthist to reduce.traps, or by reduce.traps to hclust
Details

reduce.traps –
Grouping may be specified explicitly via newtraps, or implicitly by span. If span is specified a clustering of detector sites will be performed with hclust and detectors will be assigned to groups with cutree. The default algorithm in hclust is complete linkage, which tends to yield compact, circular clusters; each will have diameter less than or equal to span.

newxy = 'first' selects the coordinates of the first detector in a group defined by 'newtraps', rather then the average of all detectors in group.

reduce.capthist –
The first component of newoccasions defines the columns of object for new occasion 1, the second for new occasion 2, etc. If newoccasions is NULL then all occasions are output. Subscripts in a component of newoccasions that do not match an occasion in the input are ignored. When the output detector is one of the trap types ('single', 'multi'), reducing capture occasions can result in locational ambiguity for individuals caught on more than one occasion, and for single-catch traps there may also be conflicts between individuals at the same trap. The method for resolving conflicts among 'multi' detectors is determined by select which should be one of 'first', 'last' or 'random'. With 'single' detectors select is ignored and the method is: first, randomly select* one trap per animal per day; second, randomly select* one animal per trap per day; third, when collapsing multiple days use the first capture, if any, in each trap.

Usage data in the traps attribute are also pooled if present; usage is summed over contributing occasions and detectors. If there is no 'usage' attribute in the input, and outputdetector is one of 'count', 'polygon', 'transect' and 'telemetry', a homogeneous (all-1's) 'usage' attribute is first generated for the input.

* i.e., in the case of a single capture, use that capture; in the case of multiple 'competing' captures draw one at random.

If newoccasions is not provided then old occasions are grouped into new occasions as indicated by the by argument. For example, if there are 15 old occasions and by = 5 then new occasions will be formed from occasions 1:5, 6:10, and 11:15. A warning is given when the number of old occasions is not a multiple of by as then the final new occasion will comprise fewer old occasions.

dropunused = TRUE has the possibly unintended effect of dropping whole occasions on which there were no detections.

A special use of the by argument is to combine all occasions into one for each session in a multi-session dataset. This is done by setting by = "all".

reduce.capthist may be used with non-spatial capthist objects (NULL 'traps' attribute) by setting verify = FALSE.

Value

reduce.traps –
An object of class traps with detectors combined according to newtraps or span. The new object has an attribute 'newtrap', a vector of length equal to the original number of detectors. Each element in newtrap is the index of the new detector to which the old detector was assigned (see Examples). The object has no clusterID or clustertrap attribute.

reduce.capthist –
An object of class capthist with number of occasions (columns) equal to length(newoccasions);
detectors may simultaneously be aggregated as with reduce.traps. The detector type is inherited
from object unless a new type is specified with the argument outputdetector.

**Warning**

The argument named ‘columns’ was renamed to ‘newoccasions’ in version 2.5.0, and arguments
were added to reduce.capthist for the pooling of detectors. Old code should work as before if all
arguments are named and ‘columns’ is changed.

**Note**

The reduce method may be used to re-assign the detector type (and hence data format) of a capthist
object without combining occasions or detectors. Set the object and outputdetector arguments
and leave others at their default values.

Automated clustering can produce unexpected outcomes. In particular, there is no guarantee that
clusters will be equal in size. You should inspect the results of reduce.traps especially when using
span.

reduce.traps is not implemented for polygons or transects.

The function discretize converts polygon data to point-detector (multi, proximity or count) data.

**See Also**

capthist, subset.capthist, discretize, hclust, cutree

**Examples**

tempcapt <- sim.capthist (make.grid(nx = 6, ny = 6), nocc = 6)
class(tempcapt)

pooled.tempcapt <- reduce(tempcapt, newocc = list(1,2:3,4:6))
summary (pooled.tempcapt)

pooled.tempcapt2 <- reduce(tempcapt, by = 2)
summary (pooled.tempcapt2)

## collapse multi-session dataset to single-session 'open population'
oneسس <- join(reduce(ovenCH, by = "all"))
summary(onesess)

# group detectors within 60 metres
plot (traps(captdata))
plot (reduce(captdata, span = 60), add = TRUE)

# plot linking old and new
old <- traps(captdata)
new <- reduce(old, span = 60)
newtrap <- attr(new, "newtrap")
plot(old, border = 10)
plot(new, add = TRUE, detpar = list(pch = 16), label = TRUE)
## region.N

### Population Size

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Estimate the expected and realised populations in a region, using a fitted spatially explicit capture-recapture model. Density is assumed to follow an inhomogeneous Poisson process in two dimensions. Expected $N$ is the volume under a fitted density surface; realised $N$ is the number of individuals within the region for the current realisation of the process (cf Johnson et al. 2010; see Note).</td>
</tr>
</tbody>
</table>
region.N

Usage

region.N(object, ...)

## S3 method for class 'secr'
region.N(object, region = NULL, spacing = NULL, session = NULL,
group = NULL, se.N = TRUE, alpha = 0.05, loginterval = TRUE,
keep.region = FALSE, nlowerbound = TRUE, RN.method = "poisson",
pooled.RN = FALSE, ncores = NULL, ...)

## S3 method for class 'secrlist'
region.N(object, region = NULL, spacing = NULL, session = NULL,
group = NULL, se.N = TRUE, alpha = 0.05, loginterval = TRUE,
keep.region = FALSE, nlowerbound = TRUE, RN.method = "poisson",
pooled.RN = FALSE, ncores = NULL, ...)

Arguments

object secr object output from secr.fit
region mask object defining the possibly non-contiguous region for which population
size is required, or vector polygon(s) (see Details)
spacing spacing between grid points (metres) if region mask is constructed on the fly
session character session
group group – for future use
se.N logical for whether to estimate SE(\hat{N}) and confidence interval
alpha alpha level for confidence intervals
loginterval logical for whether to base interval on log(N)
keep.region logical for whether to save the raster region
nlowerbound logical for whether to use n as lower bound when computing log interval for
realised N
RN.method character string for method used to calculate realised N (RN) and its sampling
variance. ‘poisson’ or ‘MSPE’.
pooled.RN logical; if TRUE the estimate of realised N for a multi-session model is com-
punted as if for combined sampling with all detectors (see Details)
ncores integer number of threads to be used for parallel processing
...
other arguments (not used)

Details

If the density surface of the fitted model is flat (i.e. object$model$D == ~1 or object$CL == TRUE)
then \(E(N)\) is simply the density multiplied by the area of region, and the standard error is also a
simple product. In the conditional likelihood case, the density and standard error are obtained by
first calling derived.
If, on the other hand, the density has been modelled then the density surface is predicted at each point in `region` and $E(N)$ is obtained by discrete summation. Pixel size may have a minor effect on the result - check by varying spacing. Sampling variance is determined by the delta method, using a numerical approximation to the gradient of $E(N)$ with respect to each beta parameter.

The region may be defined as a mask object (if omitted, the mask component of object will be used). Alternatively, `region` may be a SpatialPolygonsDataFrame object (see package `sp`), and a raster mask will be constructed on the fly using the specified spacing. See `make.mask` for an example importing a shapefile to a SpatialPolygonsDataFrame.

Note: The option of specifying a polygon rather than a mask for `region` does not work if the density model in object uses spatial covariates: these must be passed in a mask.

Group-specific $N$ has yet to be implemented.

Population size is adjusted automatically for the number of clusters in ‘mashed’ models (see `mash`). However, the population size reported is that associated with a single cluster unless `regionmask` is specified.

`pooled.RN = TRUE` handles the special case of a multi-session model in which the region of interest spans several patches (i.e., sampling in each session is localised within `region`). This is not yet fully implemented.

Setting `ncores = NULL` uses the existing value from the environment variable `RCPP_PARALLEL_NUM_THREADS` (see `setNumThreads`).

Use `par.region.N` to apply `region.N` in parallel to several models.

### Value

If `se.N = FALSE`, the numeric value of expected population size, otherwise, a dataframe with rows ‘E.N’ and ‘R.N’, and columns as below:

- `estimate` estimate of N (expected or realised, depending on row)
- `SE.estimate` standard error of estimated N
- `lcl` lower 100(1–alpha)% confidence limit
- `ucl` upper 100(1–alpha)% confidence limit
- `n` total number of individuals detected

For multiple sessions, the value is a list with one component per session, each component as above.

If `keep.region = TRUE` then the mask object for the region is saved as the attribute ‘region’ (see Examples).

The area in hectares of the region is saved as attribute ‘regionarea’.

### Note

The estimates of expected and realised $N$ are generally very similar, or identical, but realised $N$ usually has lower estimated variance, especially if the $n$ detected animals comprise a large fraction.

Realised $N$ is given by $R(N) = n + \int_B (1 - p_r(X))D(X)dX$ (the second term represents undetected animals). This definition strictly holds only when `region B` is at least as large as the region of integration used to fit the model; only with this condition can we be sure all $n$ detected animals
have centres within B. The sampling variance of $R(N)$, technically a mean square prediction error (Johnson et al. 2010), is approximated by summing the expected Poisson variance of the true number of undetected animals and a delta-method estimate of its sampling variance, obtained as for $E(N)$.

By default, a shortcut is used to compute the sampling variance of realised $N$. With this option (RN.method = ‘poisson’) the sampling variance is the sampling variance of $E(N)$ minus the estimate of $E(N)$ (representing Poisson process variance). This has been found to give reliable confidence intervals in simulations (Efford and Fewster 2013).

If RN.method is neither ‘MSPE’ nor ‘poisson’ (ignoring case) then the estimate of expected $N$ is also used for realised $N$, and the ‘poisson’ shortcut variance is used.

Johnson et al. (2010) use the notation $\mu(B)$ for expected $N$ and $N(B)$ for realised $N$ in region $B$. In our case, the relative SE (CV) of $\mu(B)$ is the same as that for the estimated density $D$ if $D$ has been estimated using the Poisson distribution option in secr.fit or derived(). If $D$ has been estimated with the binomial distribution option, its relative SE for simple models will be the same as that of $N(B)$, assuming that $B$ is the full extent of the original mask.

RMarkInput

Convert Data to RMark Input Format

Description

A single-session capthist object is formed by RMarkInput into a dataframe that may be passed directly to RMark.

Usage

RMarkInput(object, grouped = FALSE, covariates = TRUE)
unRMarkInput(df, covariates = TRUE)

Arguments

object secr capthist object
grouped logical for whether to replace each group of identical capture histories with a single line
covariates logical or character vector; see Details
df dataframe with fields ‘ch’ and ‘freq’

Details

To convert a multi-session object first collapse the sessions with join.
If covariates is TRUE the all columns of individual covariates in the input are appended as columns in the output. If covariates is a character-valued vector then only the specified covariates will be appended.
If both grouped and covariates are specified in RMarkInput, grouped will be ignored, with a warning.

Value

For RMarkInput –
Dataframe with fields ch and freq. ‘ch’ is a character string of 0’s and 1’s. If grouped = FALSE the rownames are retained and the value of ‘freq’ is 1 or -1. Negative values of ‘freq’ indicate removal.
The dataframe also includes individual covariates specified with covariates.
The attribute ‘intervals’ is copied from ‘object’, if present; otherwise it is set to a vector of zeros (indicating a closed-population sample).
For unRMarkInput –
A single-session capthist object with no traps attribute and hence no detector type (i.e. non-spatial capture histories). Covariates are copied as requested.
Note

In versions before 2.4.0, a spurious occasion was added by RMarkInput when grouped = FALSE. Thanks to Jeff Stetz for spotting this.

The default value for grouped changed to FALSE in secr 2.4.0

RMarkInput(deermouse.ESG, covariates = TRUE)

## Not run:
## fit robust-design model in RMark (MARK must be installed)
library(RMark)
MarkPath <- 'c:\MARK'  # adjust for your installation
ovenRD.data <- process.data(ovenRD, model = "Robust",
  time.interval = attr(ovenRD, "intervals"))
ovenRD.model <- mark(data = ovenRD.data, model = "Robust",
  model.parameters = list(p = list(formula = ~1, share = TRUE),
   GammaDoublePrime = list(formula = ~1),
   GammaPrime = list(formula = ~1),
   f0 = list(formula = ~1))),
cleanup(ask = FALSE)

## End(Not run)
Description

Precision of parameter estimates from an SECR model, expressed as relative standard error.

Usage

RSE(fit, parm = NULL, newdata = NULL)

Arguments

- fit: secr or openCR fitted model
- parm: character; names of one or more real parameters (default all)
- newdata: dataframe of covariates for predict.secr

Details

The relative standard error (RSE) of parameter $\theta$ is $RSE(\hat{\theta}) = \frac{SE(\theta)}{\hat{\theta}}$.

For a parameter estimated using a log link with single coefficient $\beta$, the RSE is also $RSE(\hat{\theta}) = \sqrt{\exp(\text{var}(\beta)) - 1}$. This formula is used wherever applicable.

Value

Named vector of RSE, or matrix if newdata has more than one row.

Note

The less explicit abbreviation CV has been used for the same quantity (sometimes expressed as a percentage). CV is used also for the relative standard deviation of a distribution.

CV

Examples

RSE(secrdemo.0)
Rsurface

Smoothing Resource Surface

Description

Creates a smoothed resource surface from a covariate of a mask. Smoothing entails summing the value in each pixel weighted by a detection kernel centred on the focal pixel. The detection kernel represents home-range utilization with spatial scale sigma. The resulting surface is equivalent to the denominator used by Royle et al. (2013) to normalize site-specific detection.

Usage

Rsurface(mask, sigma, usecov = NULL, alpha2 = 1, detectfn = 'HHN', z = 1, inverse = FALSE, scale = TRUE)

Arguments

- mask: secr habitat mask object (single-session)
- sigma: numeric spatial scale of home range model
- alpha2: numeric coefficient of spatial covariate
- usecov: character name of resource covariate
- detectfn: integer or character code for detection function
- z: numeric shape parameter of home range model
- inverse: logical; if TRUE the reciprocal of smoothed resource is returned
- scale: logical; not used

Details

detectfn may be uniform (‘UN’) or one of the cumulative-hazard functions (‘HHN’, ‘HHR’, ‘HEX’, ‘HAN’, ‘HCG’) (or integer codes 4, 14:18; see detectfn).

The default ‘HHN’ corresponds to a halfnormal function on the hazard scale, or a bivariate circular normal home range.

If usecov is not named then it takes the value 1.0 for all points on the mask and zero otherwise.

The Rsurface can be used implicitly to normalize detection probability when fitting a model with detector-specific covariate equal to usecov (see details, but the process is intricate and not fully documented).

Value

An object with class c(‘Rsurface’, ‘mask’, ‘data.frame’) and covariate ‘Resource’ (other covariates are retained from the input mask). The attribute ‘scale’ is 1.0 if scale = FALSE; otherwise it is the average of the resource over the masked area.
Note

Consider a focal pixel \( s \) and another point in the habitat mask \( x \), with distance \( d = |x - s| \). Weights are given by a kernel \( f(d) \). Typically the kernel will be halfnormal \( f(d) = \exp(-d^2/(2\sigma^2)) \) (detectfn = ‘HHN’) or exponential \( f(d) = \exp(-d/\sigma) \) (detectfn = ‘HEX’) (see detectfn for other possibilities).

If \( z(x) \) represents the covariate value at point \( x \), the summed resource availability at \( s \) is given by

\[
R(s) = \sum_x f(d) \exp(\alpha z(x)).
\]

This corresponds to the denominator of eqn 4 in Royle et al. (2013).

By default, the numerical values reported by Rsurface are not raw \( R \) values. If scale = TRUE, values are standardized by dividing by the mean: \( R'(s) = R(s)/(\sum_s R(s)/n) \) where \( n \) is the number of pixels. Values of \( R'(s) \) are centred on 1.0.

If inverse = TRUE, the numeric values are \( 1/R'(s) \) or \( 1/R(s) \) as determined by scale.

}
```
Score Test for SECR Models

Description
Compute score tests comparing a fitted model and a more general alternative model.

Usage
score.test(secr, ..., betaindex = NULL, trace = FALSE, ncores = NULL, .relStep = 0.001, minAbsPar = 0.1)

score.table(object, ..., sort = TRUE, dmax = 10)

Arguments
- **secr**: fitted secr model
- **...**: one or more alternative models OR a fitted secr model
- **trace**: logical. If TRUE then output one-line summary at each evaluation of the likelihood
- **ncores**: integer number of threads for parallel processing
- **.relStep**: see `fdHess`
- **minAbsPar**: see `fdHess`
- **betaindex**: vector of indices mapping fitted values to parameters in the alternative model
- **object**: score.test object or list of such objects
- **sort**: logical for whether output rows should be in descending order of AICc
- **dmax**: threshold of dAICc for inclusion in model set

Details
Score tests allow fast model selection (e.g. Catchpole & Morgan 1996). Only the simpler model need be fitted. This implementation uses the observed information matrix, which may sometimes mislead (Morgan et al. 2007). The gradient and second derivative of the likelihood function are evaluated numerically at the point in the parameter space of the second model corresponding to the fit of the first model. This operation uses the function `fdHess` of the `nlme` package; the likelihood must be evaluated several times, but many fewer times than would be needed to fit the model. The score statistic is an approximation to the likelihood ratio; this allows the difference in AIC to be estimated.

Covariates are inferred from components of the reference model `secr`. If the new models require additional covariates these may usually be added to the respective component of `secr`.

Mapping of parameters between the fitted and alternative models sometimes requires user intervention via the `betaindex` argument. For example `betaindex = c(1,2,4)` is the correct mapping.
when comparing the null model \((D \sim 1, g0 \sim 1, \sigma \sim 1)\) to one with a behavioural effect on \(g0\) \((D \sim 1, g0 \sim b, \sigma \sim 1)\).

The arguments \(.relStep\) and \(.minAbsPar\) control the numerical gradient calculation and are passed directly to \(fdHess\). More investigation is needed to determine optimal settings.

\(score.table\) summarises one or more score tests in the form of a model comparison table. The \(\ldots\) argument here allows the inclusion of additional score test objects (note the meaning differs from \(score.test\)). Approximate AICc values are used to compute relative AIC model weights for all models within \(dmax\) AICc units of the best model.

If \(ncores = NULL\) then the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS is used (see \(setNumThreads\)).

**Value**

An object of class ‘score.test’ that inherits from ‘htest’, a list with components

- **statistic**
  - the value the chi-squared test statistic (score statistic)
- **parameter**
  - degrees of freedom of the approximate chi-squared distribution of the test statistic (difference in number of parameters \(H0, H1\))
- **p.value**
  - probability of test statistic assuming chi-square distribution
- **method**
  - a character string indicating the type of test performed
- **data.name**
  - character string with null hypothesis, alternative hypothesis and arguments to function call from fit of \(H0\)
- **\(H0\)**
  - simpler model
- **np0**
  - number of parameters in simpler model
- **\(H1\)**
  - alternative model
- **\(H1.beta\)**
  - coefficients of alternative model
- **AIC**
  - Akaike’s information criterion, approximated from score statistic
- **AICc**
  - AIC with small-sample adjustment of Hurvich & Tsai 1989

If \(\ldots\) defines several alternative models then a list of score.test objects is returned.

The output from \(score.table\) is a dataframe with one row per model, including the reference model.

**Note**

This implementation is experimental. The AIC values, and values derived from them, are approximations that may differ considerably from AIC values obtained by fitting and comparing the respective models. Use of the observed information matrix may not be optimal.

## End(Not run)
```

---

**Description**

These functions are no longer available in *secr*.

**Usage**

```
# Defunct in 4.6.2 (2023-09-30)
model.average()

# Defunct in 4.5.10 (2023-03-10)
ip.secr()
pfn()

# Defunct in 4.4.2 (2021-05-04)
make.newdata()
```
secr-make.newdata()

# Defunct in 4.0.0 (2019-10-27)
read.SPACECAP()
write.SPACECAP()

## Details

- `model.average` is replaced by a method for 'secr' and 'secrlist' objects of the generic `modelAverage`. The internal code is essentially the same for `model.average` and `modelAverage.secrlist`. The generic avoids a name conflict with RMark and is also used in `openCR`.
- `ip.secr` and `pfn` have been superceded by `ipsecr.fit` and `proxy.ms` in package `ipsecr`.
- Internal functions `secr.make.newdata` and `make.newdata` were replaced with `makeNewData` generic from 4.4.2.
- `SPACECAP` was removed from the CRAN archive on 2019-08-31.

secr.design.MS  Construct Detection Model Design Matrices and Lookups

Description
Internal functions used by secr.fit.

Usage

secr.design.MS (capthist, models, timecov = NULL, sessioncov = NULL,
groups = NULL, hcov = NULL, dframe = NULL, naive = FALSE, CL = FALSE,
keep.dframe = FALSE, full.dframe = FALSE, ignoreusage = FALSE, contrasts = NULL, ...)

make.lookup (tempmat)

insertdim (x, dimx, dims)

Arguments
capthist capthist object
models list of formulae for parameters of detection
timecov optional dataframe of values of time (occasion-specific) covariate(s).
sessioncov optional dataframe of values of session-specific covariate(s).
groups optional vector of one or more variables with which to form groups. Each element should be the name of a factor variable in the covariates attribute of capthist.
hcov character name of an individual (capthist) covariate for known class membership in h2 models
dframe optional data frame of design data for detection parameters
naive logical if TRUE then modelled detection probability is for a naive animal (not caught previously); if FALSE then detection probability is contingent on individual’s history of detection
CL logical; TRUE for model to be fitted by maximizing the conditional likelihood
keep.dframe logical; if TRUE the dataframe of design data is included in the output
full.dframe logical; if FALSE then padding rows are purged from output dframe (ignored if keep.dframe = FALSE)
ignoreusage logical; if TRUE any usage attribute of traps(capthist) is ignored
contrasts contrast specification as for model.matrix
... other arguments passed to the R function model.matrix
tempmat matrix for which row lookup required
x vector of character, numeric or factor values
dimx vector of notional dimensions for x to fill in target array
dims vector of notional dimensions of target array
Details

This is an internal `secr` function that you are unlikely ever to use. ... may be used to pass `contrasts.arg` to `model.matrix`.

Each real parameter is notionally different for each unique combination of session, individual, occasion, detector and latent class, i.e., for \( R \) sessions, \( n \) individuals, \( S \) occasions and \( K \) detectors there are potentially \( R \times n \times S \times K \) different values. Actual models always predict a much reduced set of distinct values, and the number of rows in the design matrix is reduced correspondingly; a parameter index array allows these to retrieved for any combination of session, individual, occasion and detector.

The `keep.dframe` option is provided for the rare occasions that a user may want to check the data frame that is an intermediate step in computing each design matrix with `model.matrix` (i.e. the data argument of `model.matrix`).

Value

For `secr.design.MS`, a list with the components

- `designMatrices` list of reduced design matrices, one for each real detection parameter
- `parameterTable` index to row of the reduced design matrix for each real detection parameter; \( \text{dim}(\text{parameterTable}) = c(\text{uniquepar}, \text{np}) \), where `uniquepar` is the number of unique combinations of parameter values (\( \text{uniquepar} < RnSKM \)) and `np` is the number of parameters in the detection model.
- `PIA` Parameter Index Array - index to row of `parameterTable` for a given session, animal, occasion and detector; \( \text{dim}(\text{PIA}) = c(R,n,S,K,M) \)
- `R` number of sessions

If `models` is empty then all components are NULL except for `PIA` which is an array of 1’s (\( M \) set to 1).

Optionally (\( \text{keep.dframe} = \text{TRUE} \)) -

- `dframe` data frame of design data, one column per covariate, one row for each \( c(R,n,S,K,M) \). For multi-session models \( n, S, K \) refer to the maximum across sessions
- `validdim` list giving the valid dimensions (\( n, S, K, M \)) before padding

For `make.lookup`, a list with components

- `lookup` matrix of unique rows
- `index` indices in lookup of the original rows

For `insertdim`, a vector with length `prod(dims)` containing the values replicated according to `dimx`.

secr.fit

Spatially Explicit Capture–Recapture

Description

Estimate animal population density with data from an array of passive detectors (traps) by fitting a spatial detection model by maximizing the likelihood. Data must have been assembled as an object of class `capthist`. Integration is by summation over the grid of points in mask.

Usage

```r
secr.fit (capthist, model = list(D~1, g0~1, sigma~1), mask = NULL, buffer = NULL,
         CL = FALSE, detectfn = NULL, binomN = NULL, start = NULL, link = list(),
         fixed = list(), timecov = NULL, sessioncov = NULL, hcov = NULL,
         groups = NULL, dframe = NULL, details = list(), method =
         "Newton-Raphson", verify = TRUE, biasLimit = 0.01, trace = NULL,
         ncores = NULL, ...)
```

Arguments

- **capthist**: `capthist` object including capture data and detector (trap) layout
- **mask**: `mask` object or (for a multi-session analysis) a list of mask objects, one for each session
- **buffer**: scalar mask buffer radius if mask not specified (default 100 m)

verify

biasLimit

trace

ncores

...
buffer and mask are alternative ways to define the region of integration (see mask). If mask is not specified then a mask of type "trapbuffer" will be constructed automatically using the specified buffer width in metres.

hcov is used to define a hybrid mixture model, used especially to model sex differences (see hcov). (Allows some animals to be of unknown class).

The length of timecov should equal the number of sampling occasions (ncol(capthist)). Arguments timecov, sessioncov and groups are used only when needed for terms in one of the model specifications. Default link is list(D="log",g0="logit", sigma="log").

If start is missing then autoini is used for D, g0 and sigma, and other beta parameters are set initially to arbitrary values, mostly zero. start may be a previously fitted model. In this case, a vector of starting beta values is constructed from the old (usually nested) model and additional betas are set to zero. Mapping of parameters follows the default in score.test, but user intervention is not allowed. From 2.10.0 the new and old models need not share all the same ‘real’ parameters, but any new real parameters, such as ‘pmix’ for finite mixture models, receive a starting value of 0 on the link scale (remembering e.g., invlogit(0) = 0.5 for parameter ‘pmix’).

binomN (previously a component of details) determines the distribution that is fitted for the number of detections of an individual at a particular detector, on a particular occasion, when the detectors are of type ‘count’, ‘polygon’ or ‘transect’:

- binomN > 1 — binomial with size binomN
- binomN = 1 — binomial with size determined by usage
- binomN = 0 — Poisson

The default with these detectors is to fit a Poisson distribution.

details is used for various specialized settings listed below. These are described separately - see details.

```
  autoini  session to use for starting values (default 1)
  centred  centre x-y coordinates
  chat     overdispersion of sighting counts Tu, Tm
  chatonly compute overdispersion for Tu and Tm, then exit
  contrasts coding of factor predictors
  convexpolygon allows non-convex polygons (slower)
  Dfn      reparameterization of density model (seldom used directly)
  Dlambda  switch density reparameterization to trend model
  distribution binomial vs Poisson N
  fastproximity special handling of binary proximity detectors
  fixedbeta specify fixed beta parameter(s)
  grain    grain argument of RcppParallel::parallelFor
  hessian  variance method
  ignoreusage override usage in traps object of capthist
  intwidth2 controls optimise when only one parameter
  knownmarks known or unknown number of marked animals in sighting-only model
  LLonly   compute one likelihood for values in start
  maxdistance distance threshold for selective mask
  miscparm starting values for extra parameters fitted via userdist function
  newdetector detector type to override detector(traps(capthist))
```
nsim  number of simulations to compute overdispersion
param  optional parameterisation code
savecall  optionally suppress saving of call
telemetrytype  treat telemetry data as independent, dependent or concurrent
normalize  rescale detection to individual range use
usecov  spatial covariate of use for normalization
userdist  user-provided distance function or matrix

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).

A mark-resight model is fitted if the markocc attribute of the capthist ‘traps’ object includes sighting occasions. See the vignette secr-markresight.pdf for a full account.

If method = "Newton-Raphson" then nlm is used to maximize the log likelihood (minimize the negative log likelihood); otherwise optim is used with the chosen method ("BFGS", "Nelder-Mead", etc.). If maximization fails a warning is given appropriate to the method.

From secr 2.5.1, method = "none" may be used to skip likelihood maximization and compute only the hessian for the current dataset at the values in start, and the corresponding variance-covariance matrix of beta parameters. The computation uses fdHess from nlme.

If verify = TRUE then verify is called to check capthist and mask; analysis is aborted if "errors" are found. Some conditions that trigger an "error" are benign (e.g., no detections in some sessions of a multi-session study of a sparse population); use verify = FALSE to avoid the check. See also Note.

If buffer is used rather than mask, and biasLimit is valid, then the estimated density is checked for bias due to the choice of buffer. A warning is generated when buffer appears to be too small (predicted RB(D-hat) > biasLimit, default 1% relative bias). The prediction uses bias.D. No check is performed when mask is specified, when biasLimit is 0, negative or NA, or when the detector type is "polygon", "transect", "polygonX" or "transectX".

Function par.secr.fit is a way to fit several models at once.

Value

When details$LLonly = TRUE a single log-likelihood is returned, with attributes

npar  number of parameters to be estimated,
preptime  elapsed setup time in seconds,
LLtime  elapsed time for single likelihood evaluation, exclusive of setup.

Otherwise, secr.fit returns an object of class secr representing the fitted SECR model. This has components

call  function call

version secr version number
starttime character string of date and time at start of fit
proctime processor time for model fit, in seconds

The environment variable RCPP_PARALLEL_NUM_THREADS is updated if an integer value is provided for ncores.

Warning

** Mark-resight data formats and models are experimental in secr 2.10.0 and subject to change **
Note

One system of units is used throughout secr. Distances are in metres and areas are in hectares (ha). The unit of density is animals per hectare. 1 ha = 10000 m^2 = 0.01 km^2. To convert density to animals / km^2, multiply by 100.

When you display an ‘secr’ object by typing its name at the command prompt, you implicitly call its ‘print’ method print.secr, which in turn calls predict.secr to tabulate estimates of the ‘real’ parameters. Confidence limits (lcl, ucl) are for a 100(1-alpha)% interval, where alpha defaults to 0.05 (95% interval); alpha may be varied in print.secr or predict.secr.

AIC, logLik and vcov methods are also provided. Take care with using AIC: not all models are comparable (see Notes section of AIC.secr) and large differences in AIC may relate to trivial differences in estimated density.

derived is used to compute the derived parameters ‘esa’ (effective sampling area) and ‘D’ (density) for models fitted by maximizing the conditional likelihood (CL = TRUE).

Components ‘version’ and ‘starttime’ were introduced in version 1.2.7, and recording of the completion time in ‘fitted’ was discontinued.

The Newton-Raphson algorithm is fast, but it sometimes fails to compute the information matrix correctly, causing some or all standard errors to be set to NA. This usually indicates a major problem in fitting the model, and parameter estimates should not be trusted. See Troubleshooting.

The component D in output was replaced with N from version 2.3. Use region.N to obtain SE or confidence intervals for N-hat, or to infer N for a different region.

Prior to version 2.3.2 the buffer bias check could be switched off by setting verify = FALSE. This is now done by setting biasLimit = 0 or biasLimit = NA.

## Goodness-of-Fit Test

### Description

Simple Monte-Carlo goodness-of-fit tests for full-likelihood SECR models. The approach is to calculate a statistic from either the raw data or a fitted model, and to relate this to the distribution of the statistic under the original fitted model. The distribution is estimated by simulating data from the model, and possibly re-fitting the model to each simulated dataset.

The suitability of different test statistics has yet to be assessed.

### Usage

```r
secr.test(object, nsim = 99, statfn, fit = FALSE, seed = NULL, ncores = NULL, tracelevel = 1)
```

### Arguments

- **object**: a fitted secr model
- **nsim**: integer number of replicates
- **statfn**: function to compute a numeric vector of one or more statistics from a single-session `capthist` object or from a fitted model (see Details)
fit logical; if TRUE the model is re-fitted to each simulated dataset
seed either NULL or an integer that will be used in a call to set.seed
ncores integer number of threads for parallel processing
tracelevel see sim.secr

Details

The test statistic(s) may be computed either on a dataset or on a fitted model, as determined by the argument fit. The single argument expected by statfn should be either a ‘capthist’ object (fit = FALSE) or an ‘secr’ object (fit = TRUE).

The default statistic when fit = FALSE is the proportion of individuals observed on only one occasion, which is equivalent to statfn = function(CH) c(f1 = sum(apply(abs(CH) > 0,1,sum) == 1) / nrow(CH)). Repeat detections on one occasion at the same or different detectors are not counted. The default statistic is therefore not appropriate for some data, specifically from ‘count’ or ‘polygon’ detectors with few occasions or only one.

The default statistic when fit = TRUE is the deviance divided by the residual degrees of freedom (i.e., statfn = function(object) c(devdf = deviance(object) / df.residual(object))).

The reported probability (p) is the rank of the observed value in the vector combining the observed value and simulated values, divided by (nsim + 1). Ranks are computed with rank using the default ties.method = "average".

Simulations take account of the usage attribute of detectors in the original capthist object, given that usage was defined and ignoreusage was not set.

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).

statfn may return a vector of statistics for each observed or simulated dataset or model: then the value of each statistic will be calculated for every simulated dataset, and summarised. If fit = TRUE the vector of statistics may include both those computed on the raw data (object$capthist) and the fitted model.

Value

An object of class c('secrtest','list') with components:

object as input
nsim as input
statfn as input
fit as input
seed as input
output list comprising the simulated values, the observed value(s), and estimated probabilities

For multi-session input when fit = FALSE, ‘output’ is a list in which each session provides one component.

Print and plot methods are provided for ‘secrtest’ objects.
**Note**

simulate.secr is always used to simulate the raw data, but simulate.secr does not work for all types of fitted model. Models fitted by maximizing the likelihood conditional on \( n \) (CL = TRUE in secr.fit) potentially include individual covariates whose distribution in the population is unknown. This precludes simulation, and conditional-likelihood models in general are therefore not covered by secr.test.

Other exclusions include exotic non-binary behavioural responses ("bn", "bkn", "bkc", "Bkc" - but these are generally undocumented in any case).

If fit = TRUE then sim.secr is used.

At each simulation a new population is generated across the extent of the original mask. If the extent is unduly large then time will be wasted simulating the possibility of detection for many essentially undetectable animals. This is an argument for keeping the mask tight - large enough only to avoid mask-induced bias.

**Examples**

```r
## Not run:
secr.test(secrdemo.0, nsim = 99)

secr.test(ovenbird.model.1, nsim = 20)

## example combining raw data summary and model fit
## assumes single-session
bothfn <- function(object) {
  CH <- object$capthist
  f1 <- sum(apply(abs(CH) > 0, 1, sum) == 1) / nrow(CH)
  devdf <- deviance(object) / df.residual(object)
  c(f1 = f1, devdf = devdf)
}

## End(Not run)
```

**secrdemo**

SECR Models Fitted to Demonstration Data
Description

Demonstration data from program Density are provided as text files in the 'extdata' folder, as raw dataframes (trapXY, captXY), and as a combined capthist object (captdata) ready for input to secr.fit.

The fitted models are objects of class secr formed by

```r
secrdemo.0 <- secr.fit (captdata)
secrdemo.b <- secr.fit (captdata, model = list(g0 = ~b))
secrdemo.CL <- secr.fit (captdata, CL = TRUE)
```

Usage

data(secrdemo)

Details

The raw data are 235 fictional captures of 76 animals over 5 occasions in 100 single-catch traps 30 metres apart on a square grid with origin at (365,365).

Dataframe `trapXY` contains the data from the Density input file ‘trap.txt’, and `captXY` contains the data from ‘capt.txt’ (Efford 2012).

The fitted models use a halfnormal detection function and the likelihood for multi-catch traps (expect estimates of g0 to be biased because of trap saturation Efford et al. 2009). The first is a null model (i.e. parameters constant) and the second fits a learned trap response.

### Description

The use of random number seeds in `secr` is explained.

### Random numbers in `R`

`R` provides several kinds of random number generator (RNG) in the `base` package (see `RNG`). These are used both explicitly, in functions such as `runif` and `rnorm`, and implicitly (`sample`).

A seed suitable for any kind of RNG is held in a vector of 626 integers named `.Random.seed`. The vector is not to be modified directly by users. Instead, to start a reproducible stream of random numbers, the user calls `set.seed` with a single non-null integer argument. This has the effect of initialising `.Random.seed`. The value of `.Random.seed` may nevertheless be stored and restored to reset the RNG state.

`set.seed` with a NULL argument initialised `.Random.seed` to an indeterminate (time- and process-dependent) value. The same happens if a random number function is called before `.Random.seed` has been set.
Handling of RNG seed for simulation in package stats

The ‘official’ approach to setting and storing the RNG seed is shown in code and documentation for the generic function simulate in the stats package.

- The generic has argument ‘seed’ with default NULL.
- If ‘seed’ is non-null then set.seed is called.
- The returned value has an attribute “seed” whose value is either (i) if specified, the integer value of the ‘seed’ argument (with its own attribute “kind” from RNGkind), or (ii) the original vector .Random.seed.
- On exit the RNG state in .Random.seed is reset to the value that applied when the function was called.

For NULL seed input, the saved RNGstate may be used to reset .Random.seed (see Examples).

Use of random numbers in secr

Many functions in secr call on random numbers, sometimes in unexpected places. For example autoini selects a random sample to thin points and speed computation. In most functions there is no provision for direct control of the random number state: users won’t usually care, and if they do then set.seed may be called for the particular R session. Exceptions are ip.secr and par.secr.fit; both allow control of the seed, but do not save it.

However, control of the RNG seed is required for reproducible data generation in simulation functions. These functions typically have a ‘seed’ argument that is used internally in a call to set.seed. Handling of seeds in the simulation functions of secr largely follows stats::simulate as described in the preceding section.

The relevant functions are –

<table>
<thead>
<tr>
<th>Function</th>
<th>Default</th>
<th>Saved attribute</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>randomHabitat</td>
<td>NULL</td>
<td>seed or RNGstate</td>
<td></td>
</tr>
<tr>
<td>secr.test</td>
<td>NULL</td>
<td>seed or RNGstate</td>
<td>calls and retains seed from simulate.secr</td>
</tr>
<tr>
<td>sim.capthist</td>
<td>NULL</td>
<td>seed or RNGstate</td>
<td></td>
</tr>
<tr>
<td>sim.resight</td>
<td>NULL</td>
<td>seed or RNGstate</td>
<td>Seed may be passed in...argument</td>
</tr>
<tr>
<td>sim.popn</td>
<td>NULL</td>
<td>seed or RNGstate</td>
<td></td>
</tr>
<tr>
<td>sim.secr</td>
<td>NULL</td>
<td>seed or RNGstate</td>
<td></td>
</tr>
<tr>
<td>simulate.secr</td>
<td>NULL</td>
<td>seed or RNGstate</td>
<td>S3 method called by sim.secr</td>
</tr>
</tbody>
</table>

Setting seed = NULL in any of these functions has the effect of continuing the existing random number stream; it is not the same as calling set.seed(NULL). Two functions at present do not follow this model: ip.secr and par.secr.fit.

Parallel processing

Two models are used for parallel processing in secr, corresponding to multi-threading with package RcppParallel (e.g. secr.fit) and parallel cores in package parallel (e.g. ip.secr).

In the parallel model the L’Ecuyer pseudorandom generator is used to provide a separate random number stream for each core (see clusterSetRNGStream).
When using **Rcpp** the state of the random number generator is set in C++ with the call `RNGScope scope` that automatically resets the state of the generator on exit (Eddelbuettel 2013 p. 115).

Random number streams in separate **RcppParallel** threads are (probably) not independent. Thus there are potential issues with RNG calls in multi-threaded code. However, in **secr** 4.0 all RNG calls in C++ code are outside multi-threaded contexts, with the exception of simulations allowing for overdispersion in mark–resight estimates (Rcpp exported function `sightingchatcpp`). The implications for mark-resight estimates have not been explored, and it is unclear whether more elaborate solutions are needed.

```r
## Not run:

lmfit <- lm(speed ~ dist, data = cars)

## 1. NULL seed
r1 <- simulate(lmfit, seed = NULL)
r2 <- simulate(lmfit, seed = NULL)
## restore RNGstate, assuming RNGkind unchanged
.Random.seed <- attr(r1, "seed")
r3 <- simulate(lmfit, seed = NULL)
r1[1:6,1]
r2[1:6,1]
r3[1:6,1]

## 2. explicit seed
r4 <- simulate(lmfit, seed = 123)
r5 <- simulate(lmfit, seed = attr(r4, "seed"))
r4[1:6,1]
r5[1:6,1]

## End(Not run)
```

---

**secrtest**

*Goodness-of-fit Test Results*

**Description**

S3 class for results from `secr.test`.  

Usage

```r
## S3 method for class 'secrtest'
print(x, terse = TRUE, ...)
## S3 method for class 'secrtest'
plot(x, stat, ...)
```

Arguments

- `x`: secrtest object from `secr.test`
- `terse`: logical; if TRUE only p values are displayed
- `stat`: character; names of statistics to plot (default: all)
- `...`: other arguments passed to hist by `plot.secrtest`

Details

An 'secrtest' object is output from `secr.test`. `plot.secrtest` plots a histogram of the simulated values.

If `plot.secrtest` is applied to an object with more than one statistic then multiple plots are produced, so a multi-figure layout should be prepared (`par(mfrow = c(1,2))` for 2 plots side by side). Include the hist argument `main = ''` to suppress the ugly plot labels, and ensure each statistic is named by `statfn` so that the x-axis is labelled correctly (See the Examples in help for `secr.test`).

See Also

- `secr.test`

Examples

```r
## Not run:

tmp <- secr.test(ovenbird.model.1)
if (inherits(tmp, 'secrtest')) {
  tmp  ## terse print
  print(tmp, terse = FALSE)
  par(mfrow = c(1,5))
  plot(tmp, main = '', xlim=c(0,1), breaks=seq(0,1,0.05))
  par(mfrow = c(1,1))  ## reset to default
}

## End(Not run)
```
Description

Extract or replace the session names of a capthist object.

Usage

```r
session(object, ...)  
session(object) <- value
```

Arguments

- `object`: object with ‘session’ attribute e.g. capthist
- `value`: character vector or vector that may be coerced to character, one value per session
- `...`: other arguments (not used)

Details

Replacement values will be coerced to character.

Value

a character vector with one value for each session in capthist

Note

Like Density, secr uses the term ‘session’ for a closed-population sample. A session usually includes data from several closely-spaced capture occasions (often consecutive days). Each ‘primary session’ in the ‘robust’ design of Pollock (1982) would be treated as a session in secr. secr also uses ‘session’ for independent subsets of the capture data distinguished by characteristics other than sampling time (as above). For example, two grids trapped simultaneously could be analysed as distinct sessions if (i) they were far enough apart that there was negligible prospect of the same animal being caught on both grids, and (ii) there was interest in comparing estimates from the two grids, or fitting a common detection model.

The log likelihood for a session model is the sum of the separate session log likelihoods. Although this assumes independence of sampling, parameters may be shared across sessions, or session-specific parameter values may be functions of session-level covariates. For many purposes, ‘sessions’ are equivalent to ‘groups’. For multi-session models the detector array and mask are specified separately for each session. Group models are therefore generally simpler to implement. On the other hand, sessions offer more flexibility in defining and evaluating between-session models, including trend models.

**setNumThreads**

**See Also**

capthist

**Examples**

```r
session(captdata)
```

---

### Description

Set or report the number of cores to be used for multi-threaded operations. A wrapper for the RcppParallel function setThreadOptions (Allaire et al. 2019).

**Usage**

```r
setNumThreads(ncores, ...)
```

**Arguments**

- `ncores` integer number of threads to use
- `...` other arguments passed to RcppParallel::setThreadOptions, specifically stack-Size

**Details**

If `ncores` is NULL then the current value of the environment variable RCPP_PARALLEL_NUM_THREADS is used. RCPP_PARALLEL_NUM_THREADS defaults to 2 at the start of a session (assuming at least 2 logical cores available).

Calling `setNumThreads()` with no arguments is a handy way to check how many threads are in use.

The value of RCPP_PARALLEL_NUM_THREADS is also reset when a multi-threaded function such as secr.fit is called with a non-NULL value of the ncores argument. This value applies in later calls of secr.fit with ncores = NULL until changed.

**Value**

The new value of the environment variable RCPP_PARALLEL_NUM_THREADS.

**Note**

The mechanism for setting the number of threads changed between versions 4.1.0 and 4.2.0. The default number of cores is now capped at 2 to meet CRAN requirements. Setting `ncores = NULL` previously specified one less than the number of available cores.
References

Parallel, setThreadOptions Sys.getenv

Examples

# determine current number of threads
setNumThreads()

## Not run:
# set new number of threads
setNumThreads(7)

# a call to secr.fit that specifies 'ncores' also sets the
# number of threads, as we see here
fit <- secr.fit(capdata, trace = FALSE, ncores = 8)
setNumThreads()

## End(Not run)

shareFactorLevels  Fix Inconsistent Covariates

Description

Factor covariates can give trouble in multi-session models if the levels differ among sessions. A warning is provided by verify.capthist. This function forces factor covariates to use the same levels.

Usage

shareFactorLevels(object, columns = NULL, stringsAsFactors = TRUE)
Arguments

- **object**: multi-session capthist object or list of traps or mask objects
- **columns**: indices of columns to fix (default all)
- **stringsAsFactors**: logical; if TRUE then character columns are converted to factor

Details

Factor-valued covariates are coerced to use the same set of levels for each session of a multi-session capthist object or each component of a list of traps or masks. The combined level set is the union of all levels in separate sessions. The order of levels follows the default in `factor` (alphabetical according to current locale).

Setting `stringsAsFactors = TRUE` causes character-valued columns to be converted to factors.

Value

An object of the same class as input. A single-session object is passed unchanged except for possible conversion of character values to factor (`stringsAsFactors = TRUE`).

See Also

- `verify.capthist`

sighting

Sighting Attributes

Description

Extract or replace the `markocc` attribute of a `traps` object that distinguishes marking occasions from sighting occasions. Also, extract or replace the attributes `Tu`, `Tm` and `Tn` of a capthist object, used for storing counts of sightings. All attributes are optional, but `Tu`, `Tm` and `Tn` require `markocc` to be specified.

Usage

```r
markocc(object, ...)  # Extracts the markocc attribute
markocc(object) <- value  # Replaces the markocc attribute

sighting(object)
Tu(object, ...)
Tu(object) <- value

Tm(object, ...)
Tm(object) <- value

Tn(object, ...)
Tn(object) <- value
```
**signal**

Arguments

- **object**
  - traps object (markocc) or capthist object (Tu, Tm, Tn)
- **value**
  - numeric matrix of detectors x occasions, or a vector (see Details)
- **...**
  - other arguments (not used)

Details

For replacement of markocc, 'value' should be a vector of integers indicating the occasions on which animals are sighted only (0) or marked or recaptured (1).

For replacement of Tu, Tm or Tn, 'value' may be a scalar (total count) or a detectors x occasions matrix.

Value

markocc(object) returns the markocc vector of the traps object. markocc(object) may be NULL.

Tu, Tm and Tn return the respective attributes of a capthist object, or NULL if they are unspecified.

sighting(object) returns TRUE if the markocc attribute indicates at least one sighting-only occasion.

- traps, addSightings, sightingPlot, secr-markresight.pdf

---

**signal**

**Signal Fields**

Description

Extract or replace signal attributes of a 'capthist' object.

Usage

```
signalframe(object)
signalframe(object) <- value

## S3 method for class 'capthist'
signal(object, ...)
## S3 method for class 'capthist'
noise(object, ...)

signal(object) <- value
noise(object) <- value
```
Arguments

- **object**: a ‘capthist’ object
- **value**: replacement value (see Details)
- **...**: other arguments (not used)

Details

Signal attributes of a ‘capthist’ object are stored in a dataframe called the signalframe. This has one row per detection. The signalframe includes the primary field ‘signal’ and an unlimited number of other fields. To extract the signal field alone use the signal method.

These functions extract data on detections, ignoring occasions when an animal was not detected. Detections are ordered by occasion, animalID and trap.

Replacement values must precisely match object in number of detections and in their order.

Value

For **signalframe**, a dataframe containing signal data and covariates, one row per detection. The data frame has one row per detection. See **signalmatrix** for a matrix with one row per cue and columns for different microphones.

For **signal** and **noise**, a numeric vector with one element per detection.

If object has multiple sessions, the result is a list with one component per session.

See Also

capthist, signalmatrix

Examples

```r
## ovensong dataset has very simple signalframe
head(signalframe(signalCH))
```

---

**signalmatrix**

Reformat Signal Data

Description

Produce sound x microphone matrix, possibly with sound covariates as extra columns.

Usage

```r
signalmatrix(object, noise = FALSE, recodezero = FALSE,
            prefix = "Ch", signalcovariates = NULL, names = NULL)
```
Arguments

- **object**: object inheriting from secr class 'capthist'
- **noise**: logical; if TRUE, noise is extracted instead of signal
- **recodezero**: logical; if TRUE zero signals are set to NA
- **prefix**: character value used to form channel names
- **signalcovariates**: character vector of covariate names from signalframe to add as columns
- **names**: character vector of column names

Details

This function extracts signal or noise data from a capthist object, where it is stored in the 'signal-frame' attribute, as a more natural sound x microphone table. There is no equivalent replacement function.

The `signalcovariates` argument may be used to specify additional columns of the signal frame to collapse and add as columns to the right of the actual signal data. Ordinarily there will be multiple rows in signalframe for each row in the output; the covariate value is taken from the first matching row.

If `names` is not provided, column names are constructed from the detector names. If the length of `names` is less than the number of columns, simple numerical names are constructed.

Value

A dataframe with dim = c(n,K+j) where n is the number of separate sounds, K is the number of microphones, and j is the number of covariates (by default j = 0).

- **ovensong**

Examples

```r
## use 'secr' ovenbird data
signalmatrix(signalCH)
```

Description

Create a set of capture or marking-and-resighting histories by simulated sampling of a 2-D population using an array of detectors.
Usage

```r
sim.capthist(traps, popn = list(D = 5, buffer = 100, Ndist = "poisson"), detectfn = 0, detectpar = list(), noccasions = 5, nsessions = 1, binomN = NULL, exactN = NULL, p.available = 1, renumber = TRUE, seed = NULL, maxperpoly = 100, chulltol = 0.001, userdist = NULL, savepopn = FALSE)

sim.resight(traps, popn = list(D = 5, buffer = 100, Ndist = "poisson"), ..., pID = 1, unmarked = TRUE, nonID = TRUE, unresolved = FALSE, unsighted = TRUE, pmark = 0.5, Nmark = NULL, markingmask = NULL)
```

Arguments

- **traps**: locations object with the locations and other attributes of detectors
- **popn**: locations of individuals in the population to be sampled, either as a `popn` object (see `sim.popn`) or a list with the named components.
- **detectfn**: integer code or character string for shape of detection function 0 = halfnormal etc. – see `detectfn`
- **detectpar**: list of values for named parameters of detection function
- **noccasions**: number of occasions to simulate
- **nsessions**: number of sessions to simulate
- **binomN**: integer code for distribution of counts (see Details)
- **exactN**: integer number of telemetry fixes per occasion
- **p.available**: vector of one or two probabilities (see Details)
- **renumber**: logical for whether output rows should labeled sequentially (TRUE) or retain the numbering of the population from which they were drawn (FALSE)
- **seed**: either NULL or an integer that will be used in a call to `set.seed`
- **maxperpoly**: integer maximum number of detections of an individual in one polygon or transect on any occasion
- **chulltol**: numeric buffer (m) for polygon around telemetry locations
- **userdist**: user-defined distance function or matrix (see details)
- **savepopn**: logical; if TRUE then the popn (input or simulated) is saved as an attribute
- **...**: arguments to pass to `sim.capthist`
- **pID**: probability of individual identification for marked animals
- **unmarked**: logical, if TRUE unmarked individuals are not recorded during 'sighting'
- **nonID**: logical, if TRUE then unidentified marked individuals are not recorded during 'sighting'
- **unresolved**: logical, if TRUE then individuals of unresolved mark status are not recorded during 'sighting'
- **unsighted**: logical, if TRUE and sighting only then capthist includes all-zero histories
- **pmark**: numeric probability that an individual is 'pre-marked' (see Details)
- **Nmark**: number of individuals to be 'pre-marked' (see Details)
- **markingmask**: mask object
Details

If `popn` is not of class ‘popn’ then a homogeneous Poisson population with the desired density (animals/ha) is first simulated over the rectangular area of the bounding box of `traps` plus a buffer of the requested width (metres). The detection algorithm depends on the detector type of `traps`. For ‘proximity’ detectors, the actual detection probability of animal `i` at detector `j` is the naive probability given by the detection function. For ‘single’ and ‘multi’ detectors the naive probability is modified by competition between detectors and, in the case of ‘single’ detectors, between animals. See Efford (2004) and other papers below for details.

Detection parameters in `detectpar` are specific to the detection function, which is indicated by `detectfn`. Parameters may vary with time - for this provide a vector of length `noccasions`. The g0 parameter may vary both by time and detector - for this provide a matrix with `noccasions` rows and as many columns as there are detectors. The default detection parameters are `list(g0 = 0.2, sigma = 25, z = 1)`.

The default is to simulate a single session. This may be overridden by providing a list of populations to sample (argument `popn`) or by specifying `nsessions > 1` (if both then the number of sessions must match). Using `nsessions > 1` results in replicate samples of populations with the same density etc. as specified directly in the `popn` argument.

`binomN` determines the statistical distribution of the number of detections of an individual at a particular ‘count’ detector or polygon on a particular occasion. A Poisson distribution is indicated by `binomN = 0`; see `secr.fit` for more. The distribution is always Bernoulli (binary) for ‘proximity’ and ‘signal’ detectors.

If `exactN` is not specified or zero then the number of telemetry fixes is a random variable determined by the other detection settings.

`p.available` specifies temporary non-availability for detection in multi-session simulations. If a single probability is specified then temporary non-availability is random (independent from session to session). If two probabilities are given then non-availability is Markovian (dependent on previous state) and the two values are for animals available and not available at the preceding session. In the Markovian case, availability in the first session is assigned at random according to the equilibrium probability `p2 / (1 - p1 + p2)`. Incomplete availability is not implemented for sampling lists of populations.

`detectpar` may include a component ‘truncate’ for the distance beyond which detection probability is set to zero. By default this value is `NULL` (no specific limit).

`detectpar` may also include a component ‘recapfactor’ for a general learned trap response. For ‘single’ and ‘multi’ detector types the probability of detection changes by this factor for all occasions after the occasion of first capture. Attempted use with other detector types causes an error. If `recapfactor` x `g(d)` > 1.0, `g(d)` is truncated at 1.0. Other types of response (site-specific bk, Markovian B) are not allowed.

If `popn` is specified by an object of class ‘popn’ then any individual covariates will be passed on; the `covariates` attribute of the output is otherwise set to `NULL`.

The random number seed is managed as in `simulate`.

`chulltol` is used only when simulating telemetry locations. By default, a new ‘traps’ polygon is generated as the convex hull of the simulated locations, with a slight (1 mm) added buffer to ensure boundary points are within the polygon. Buffering is suppressed if `chulltol` is `NA` or negative.

`userrdist` cannot be set if ‘traps’ is any of polygon, polygonX, transect or transectX.
`sim.capthist` generates mark-resight data. The ‘markocc’ attribute of ‘traps’ indicates the occasions which are for sighting-only (0) or marking and recapture (1). The number of occasions is determined by `markocc`. `sim.capthist` is first called with the arguments ‘traps’ and …. The detector type of ‘traps’ should be ‘proximity’ or ‘count’ for sighting occasions (markocc = 0). The detector type need not be the same for marking and sighting occasions (‘multi’ is allowed on marking occasions). If … includes a non-null ‘seed’ the random seed is reset in `sim.resight` and not passed to `sim.capthist`.

A special case arises when all occasions are sighting-only. Then it is assumed that individuals in the population are marked prior to the start of sampling with a known spatial distribution (i.e. marking does not follow a spatial detection model). By default, animals throughout the buffered area are pre-marked with probability `pmark`. If `Nmark` is specified then a sample of size `Nmark` will be selected for marking, overriding `pmark`.

The marked population may be restricted to a subset of the space spanned by `popn` by specifying `markingmask`, which may have a further covariate ‘marking’ to vary the intensity of marking.

**Value**

For `sim.capthist`, an object of class `capthist`, a 3-dimensional array with additional attributes. Rows represent individuals and columns represent occasions; the third dimension, codes the number of detections at each detector (zero or one for trap detectors (‘single’, ‘multi’) and binary proximity detectors).

The initial state of the R random number generator is stored in the ‘seed’ attribute.

For `sim.resight`, an object of class `capthist` for which the traps object has a markocc attribute (marking occasions), and there are further attributes `Tu` (sightings of unmarked animals) and `Tm` (sightings of marked but not identified animals).

**Note**

External code is called to speed the simulations. The present version assumes a null model, i.e., naive detection probability is constant except for effects of distance and possibly time (using vector-valued detection parameters from 1.2.10). You can, however, use `rbind.capthist` to combine detections of population subclasses (e.g. males and females) simulated with different parameter values. This is not valid for detector type “single” because it fails to allow for competition for traps between subclasses. Future versions may allow more complex models.

`truncate` has no effect (i) when using a uniform detection function with radius (sigma) <= `truncate` and (ii) with signal strength detection (detectfn 10, 11). Note that truncated detection functions are provided for de novo simulation, but are not available when fitting models with in `secr.fit` or simulating from a fitted model with `sim.secr`.

`maxperpoly` limits the size of the array allocated for detections in C code; an error results if the is number is exceeded.

Prior to 2.10.0 `sim.resight` interpreted length-2 vectors of detection parameters as referring to marking and sighting occasions; this feature has been discontinued.

Examples

```r
## simple example
## detector = "multi" (default)
temptrap <- make.grid(nx = 6, ny = 6, spacing = 20)
sim.capthist (temptrap, detectpar = list(g0 = 0.2, sigma = 20))

## with detector = "proximity", there may be more than one
## detection per individual per occasion
temptrap <- make.grid(nx = 6, ny = 6, spacing = 20, detector = "proximity")
sim.capthist (temptrap, detectpar = list(g0 = 0.2, sigma = 20))

## marking on occasions 1, 3 only
markocc(temptrap) <- c(1,0,1,0,0)
CH <- sim.capthist (temptrap, detectpar = list(g0 = 0.2, sigma = 20))

## multiple sessions
grid4 <- make.grid(nx = 2, ny = 2)
temp <- sim.capthist (grid4, popn = list(D = 1), nsessions = 20)
sim.capthist (grid4, popn = list(D = 1), nsessions = 20)

## unmarked or presence types
# grid <- make.grid(nx = 10, ny = 10, detector = "unmarked")
# CH <- sim.capthist (grid, nooccasions = 5)
# CH
```

## "presence" and "unmarked" data are stored as "count" data
## behaviour is controlled by detector type, e.g.
```r
# detector(traps(CH)) <- "presence"
# CH
```
Simulate 2-D Population

**Description**

Simulate a point process representing the locations of individual animals.

**Usage**

```r
sim.popn(D, core, buffer = 100, model2D = c("poisson", "cluster", "IHP", "coastal", "hills", "linear", "even", "rLGCP", "rThomas"), buffertype = c("rect", "concave", "convex"), poly = NULL, covariates = list(sex = c(M = 0.5, F = 0.5)), number.from = 1, Ndist = c("poisson", "fixed", "specified"), nsessions = 1, details = NULL, seed = NULL, keep.mask = model2D %in% c("IHP", "linear"), Nbuffer = NULL, age = FALSE, ...) tile(popn, method = "reflect")
```

**Arguments**

- **D**: density animals / hectare (10 000 m^2) (see Details for IHP case)
- **core**: data frame of points defining the core area
- **buffer**: buffer radius about core area
- **model2D**: character string for 2-D distribution
- **buffertype**: character string for buffer type
- **poly**: bounding polygon (see Details)
- **covariates**: list of named covariates
- **number.from**: integer ID for animal
- **Ndist**: character string for distribution of number of individuals
- **nsessions**: number of sessions to simulate
- **details**: optional list with additional parameters
- **seed**: either NULL or an integer that will be used in a call to `set.seed`
- **keep.mask**: logical; if TRUE and `model2D %in% c("IHP", "linear")` then core is saved as the attribute "mask"
- **Nbuffer**: integer number of individuals to simulate
- **age**: logical; if TRUE then age covariate added for multisession popn with turnover
- **...**: arguments passed to subset if poly is not NULL
- **popn**: popn object
- **method**: character string "reflect" or "copy"
Details

core must contain columns ‘x’ and ‘y’: a traps object is suitable. For buffertype = "rect", animals are simulated in the rectangular area obtained by extending the bounding box of core by buffer metres to top and bottom, left and right. This box has area \( A \). If model2D = 'poisson' the buffer type may also be 'convex' (points within a buffered convex polygon) or 'concave' (corresponding to a mask of type 'trapbuffer'); these buffer types use buffer.contour.

A notional random covariate ‘sex’ is generated by default.

Each element of covariates defines a categorical (factor) covariate with the given probabilities of membership in each class. No mechanism is provided for generating continuous covariates, but these may be added later (see Examples).

Ndist should usually be ‘poisson’ or ‘fixed’. The number of individuals \( N \) has expected value \( DA \). If \( DA \) is non-integer then Ndist = "fixed" results in \( N \in \{\text{trunc}(DA), \text{trunc}(DA) + 1\} \), with probabilities set to yield \( DA \) individuals on average. The option ‘specified’ is undocumented; it is used in some open-population simulations.

If model2D = "cluster" then the simulated population approximates a Neyman-Scott clustered Poisson distribution. Ancillary parameters are passed as components of details: details$mu is the expected number of individuals per cluster and details$hsigma is the spatial scale (\( \sigma \)) of a 2-D kernel for location within each cluster. The algorithm is

1. Determine the number of clusters (parents) as a random Poisson variate with \( \lambda = DA/\mu \)
2. Locate each parent by drawing uniform random x- and y-coordinates
3. Determine number of offspring for each parent by drawing from a Poisson distribution with mean \( \mu \)
4. Locate offspring by adding random normal error to each parent coordinate
5. Apply toroidal wrapping to ensure all offspring locations are inside the buffered area

A special cluster option is selected if details$clone = "constant": then each parent is cloned exactly details$mu times.

Toroidal wrapping is a compromise. The result is more faithful to the Neyman-Scott distribution if the buffer is large enough that only a small proportion of the points are wrapped.

If model2D = "IHP" then an inhomogeneous Poisson distribution is simulated. core should be a habitat mask and D should be one of –

- a vector of length equal to the number of cells (rows) in core,
- the name of a covariate in core that contains cell-specific densities (animals / hectare),
- a function to generate the intensity of the distribution at each mask point, or
- a constant.

If a function, D should take two arguments, a habitat mask and a list of parameter values (‘core’ and ‘details’ are passed internally as these arguments).

The number of individuals in each cell is either (i) Poisson-distributed with mean \( DA \) where \( A \) is the cell area (an attribute of the mask) (Ndist = "poisson") or (ii) multinomial with size \( DA \) and relative cell probabilities given by D (Ndist = "fixed"). buffertype and buffer are ignored, as the extent of the population is governed entirely by the mask in core.
If `model2D = "linear"` then a linear population is simulated as for `model2D = "IHP"`, except that core should be a linearmask object from package `secrlinear`, and density (D) is expressed in animals per km. The documentation of `secrlinear` should be consulted for further detail (e.g. the wrapper function `sim.linearpopn`).

If `model2D = "coastal"` then a form of inhomogeneous Poisson distribution is simulated in which the x- and y-coordinates are drawn from independent Beta distributions. Default parameters generate the ‘coastal’ distribution used by Fewster and Buckland (2004) for simulations of line-transect distance sampling \((x \sim \text{Beta}(1, 1.5), y \sim \text{Beta}(5, 1)\), which places 50% of the population in the ‘northern’ 13% of the rectangle). The four Beta parameters may be supplied in the vector component Beta of the ‘details’ list (see Examples). The Beta parameters \((1,1)\) give a uniform distribution. Coordinates are scaled to fit the limits of a sampled rectangle, so this method assumes buffertype = "rect".

If `model2D = "hills"` then a form of inhomogeneous Poisson distribution is simulated in which intensity is a sine curve in the x- and y- directions (density varies symmetrically between 0 and 2 x D along each axis). The number of hills in each direction (default 1) is determined by the ‘hills’ component of the ‘details’ list (e.g. details = list(hills=c(2,3)) for 6 hills). If either number is negative then alternate rows will be offset by half a hill. Displacements of the entire pattern to the right and top are indicated by further elements of the ‘hills’ component (e.g. details = list(hills=c(1,1,0.5,0.5)) for 1 hill shifted half a unit to the top right; coordinates are wrapped, so the effect is to split the hill into the four corners). Negative displacements are replaced by runif(1). Density is zero at the edge when the displacement vector is \((0,0)\) and rows are not offset.

If `model2D = "even"` then the buffered area is divided into square cells with side \(\sqrt{10000/D}\) and one animal is located at a random uniform location within each cell. If the height or width is not an exact multiple of the cell side then one whole extra row or column of cells is added; animals located at random in these cells are discarded if they fall outside the original area.

From `secr 4.6.2`, `sim.popn` provides an interface to two simulation functions from `spatstat` (Baddeley et al. 2015): `rLGCP` and `rThomas`.

If `model2D = "rLGCP"` then a log-gaussian Cox process is simulated within the buffered area. Function `rLGCP` in `spatstat` calls functions from `RandomFields` (Schlather et al. 2015; see Notes). Certain options are fixed: the correlation function is `RMexp` from `RandomFields`, and there is no provision for covariate effects. Clipping to a polygon (`poly`) and fixed-N (`Ndist = "fixed"`) are not supported. The algorithm first constructs the log spatial intensity as a realisation of a Gaussian random field; one realisation of an IHP with that intensity is then simulated.

The parameters for `model2D = "rLGCP"` are the scalar density (D) and the variance and spatial scale of the random field (passed as details arguments ‘var’ and ‘scale’). The variance is on the log scale; the mean on the log scale is computed internally as \(\mu = \log(D) - \text{var}/2\). var = 0 results in a random uniform (Poisson) distribution. The discretized intensity function is saved as the attribute "Lambda", a habitat mask with covariate "Lambda" that may be used to construct further IHP realisations (see Examples).

If `model2D = "rThomas"` then a Thomas process is simulated. This is a special case of the Neyman-Scott process in which each parent gives rise to a Poisson number of offspring (see Notes). The expected number of offspring per parent and the spatial scatter about each parent are specified by the details arguments ‘mu’ and ‘scale’. Argument ‘kappa’ of `rThomas` (density of parent process) is computed as \(D/\text{mu}/1e4\). Other arguments remain at their defaults, including ‘expand’ \((4 * \text{scale})\).

If `poly` is specified, points outside `poly` are dropped. `poly` may be one of the types described in `boundarytoSF`.
The `subset` method is called internally when `poly` is used; the ... argument may be used to pass values for `keep.poly` and `poly.habitat`.

Multi-session populations may be generated with `nsessions > 1`. Multi-session populations may be independent or generated by per capita turnover from a starting population. In the 'independent' case (details$lambda not specified) D or Nbuffer may be a vector of length equal to `nsessions`. Turnover is controlled by survival, growth rate and movement parameters provided as components of details and described in `turnover`. The optional covariate 'age' is the number of sessions from the session of recruitment.

The random number seed is managed as in `simulate.lm`.

Function `tile` replicates a `popn` pattern by either reflecting or copying and translating it to fill a 3 x 3 grid.

**Value**

An object of class c("popn", "data.frame") a data frame with columns 'x' and 'y'. Rows correspond to individuals. Individual covariates (optional) are stored as a data frame attribute. The initial state of the R random number generator is stored in the 'seed' attribute.

If `model2D = "linear"` the output is of class c("linearpopn", "popn", "data.frame").

If `model2D = "IHP"` or `model2D = "linear"` the value of core is stored in the 'mask' attribute.

**Notes**

Package RandomFields is not currently on CRAN. It may be installed with this code:

```r
```

`model2D = "rThomas"` and `model2D = "cluster"` (the builtin Neyman-Scott implementation) are equivalent. There may be some subtle differences. The `spatstat` implementation is usually to be preferred.

Simulate From Fitted secr Model

Description

Simulate a spatially distributed population, sample from that population with an array of detectors, and optionally fit an SECR model to the simulated data.

Usage

### S3 method for class 'secr'

```r
simulate(object, nsim = 1, seed = NULL, maxperpoly = 100,
          chat = 1, ...) 
```

```r
sim.secr(object, nsim = 1, extractfn = function(x) c(deviance =
          deviance(x), df = df.residual(x)), seed = NULL, maxperpoly = 100,
          data = NULL, tracelevel = 1, hessian = c("none", "auto", "fdHess"),
          start = object$fit$par, ncores = NULL) 
```

```r
sim.detect(object, popnlist, maxperpoly = 100, renumber = TRUE) 
```

Arguments

- **object**: a fitted secr model
- **nsim**: integer number of replicates
- **seed**: either NULL or an integer that will be used in a call to `set.seed`
- **maxperpoly**: integer maximum number of detections of an individual in one polygon or transect on any occasion
- **chat**: real value for overdispersion parameter
- **ncores**: integer number of threads used by `secr.fit`
- **extractfn**: function to extract output values from fitted model
- **data**: optional list of simulated data saved from previous call to `simulate.secr`
- **tracelevel**: integer for level of detail in reporting (0,1,2)
- **hessian**: character or logical controlling the computation of the Hessian matrix
- **start**: vector of starting ‘beta’ values for `secr.fit`
- **...**: other arguments (not used)
- **popnlist**: list of popn objects
- **renumber**: logical; if TRUE then
Details

For each replicate, `simulate.secr` calls `sim.popn` to generate session- and group-specific realizations of the (possibly inhomogeneous) 2-D Poisson distribution fitted in `object`, across the habitat mask(s) in `object`. Group subpopulations are combined using `rbind.popn` within each session; information to reconstruct groups is retained in the individual-level factor covariate(s) of the resulting `popn` object (corresponding to `object$groups`). Each population is then sampled using the fitted detection model and detector (trap) array(s) in `object`.

The random number seed is managed as in `simulate.lm`.

Certain model types are not supported by `simulate.secr`. These include models fitted using conditional likelihood (object$CL = TRUE), telemetry models and exotic behavioural response models.

Detector type is determined by `detector(traps(object$capthist))`.

`sim.secr` is a wrapper function. If `data = NULL` (the default) then it calls `simulate.secr` to generate `nsim` new datasets. If `data` is provided then `nsim` is taken to be `length(data)`. `secr.fit` is called to fit the original model to each new dataset. Results are summarized according to the user-provided function `extractfn`. The default `extractfn` returns the deviance and its degrees of freedom; a NULL value for `extractfn` returns the fitted `secr` objects after trimming to reduce bulk. Simulation uses the detector type of the data, even when another likelihood is fitted (this is the case with single-catch data, for which a multi-catch likelihood is fitted). Warning messages from `secr.fit` are suppressed.

`extractfn` should be a function that takes an `secr` object as its only argument.

`tracelevel=0` suppresses most messages; `tracelevel=1` gives a terse message at the start of each fit; `tracelevel=2` also sets `details$trace = TRUE` for `secr.fit`, causing each likelihood evaluation to be reported.

`hessian` controls computation of the Hessian matrix from which variances and covariances are obtained. `hessian` replaces the value in `object$details`. Options are "none" (no variances), "auto" (the default) or "fdhess" (see `secr.fit`). It is OK (and faster) to use `hessian="none"` unless `extractfn` needs variances or covariances. Logical TRUE and FALSE are interpreted by `secr.fit` as "auto" and "none".

If `ncores = NULL` then the existing value from the environment variable `RCPP_PARALLEL_NUM_THREADS` is used (see `setNumThreads`).

`sim.capthist` is a more direct way to simulate data from a null model (i.e. one with constant parameters for density and detection), or from a time-varying model.

`sim.detect` is a function used internally that will not usually be called directly.

Value

For `simulate.secr`, a list of data sets (‘capthist’ objects). This list has class c("secrdata", "list"); the initial state of the random number generator (roughly, the value of .Random.seed) is stored as the attribute ‘seed’.

The value from `sim.secr` depends on `extractfn`: if that returns a numeric vector of length `n.extract` then the value is a matrix with `dim = c(nsim, n.extract)` (i.e., the matrix has one row per replicate and one column for each extracted value). Otherwise, the value returned by `sim.secr` is a list with one component per replicate (strictly, an object of class = c("secrlist", "list")). Each simulated fit may be retrieved in toto by specifying `extractfn = identity`, or slimmed down by specifying `extractfn = NULL` or `extractfn = trim`, which are equivalent.
For either form of output from `sim.secr` the initial state of the random number generator is stored as the attribute ‘seed’.

For `sim.detect` a list of ‘capthist’ objects.

**Note**

The value returned by `simulate.secr` is a list of ‘capthist’ objects; if there is more than one session, each ‘capthist’ is itself a sort of list.

The classes ‘secrdata’ and ‘secrlist’ are used only to override the ugly and usually unwanted printing of the seed attribute. However, a few other methods are available for ‘secrlist’ objects (e.g. `plot.secrlist`).

The default value for `start` in `sim.secr` is the previously fitted parameter vector. Alternatives are `NULL` or `object$start`.

**See Also**

`sim.capthist`, `secr.fit`, `simulate`, `secr.test`

**Examples**

```r
## Not run:

## previously fitted model
simulate(secrdemo.0, nsim = 2)

## The following has been superceded by secr.test()

## this would take a long time...
sims <- sim.secr(secrdemo.0, nsim = 99)
deviance(secrdemo.0)
devs <- c(deviance(secrdemo.0), sims$deviance)
quantile(devs, probs = c(0.95))
rank(devs)[1] / length(devs)

## to assess bias and CI coverage
extrfn <- function(object) unlist(predict(object)["D",-1])
sims <- sim.secr(secrdemo.0, nsim = 50, hessian = "auto",
extractfn = extrfn)
sims

## with a larger sample, could get parametric bootstrap CI
quantile(sims[,1], c(0.025, 0.975))

## End(Not run)
```
Description

Data from a study of skinks (*Oligosoma infrapunctatum* and *O. lineoocellatum*) in New Zealand.

Usage

infraCH
lineoCH
LStraps

Details

Lizards were studied over several years on a steep bracken-covered hillside on Lake Station in the Upper Buller Valley, South Island, New Zealand. Pitfall traps (sunken cans baited with a morsel of fruit in sugar syrup) were set in two large grids, each 11 x 21 traps nominally 5 meters apart, surveyed by tape and compass (locations determined later with precision surveying equipment - see Examples). Three diurnal lizard species were trapped: *Oligosoma infrapunctatum*, *O. lineoocellatum* and *O. polychroma* (Scincidae). The smallest species *O. polychroma* was seldom caught and these data are not included. The two other species are almost equal in average size (about 160 mm total length); they are long-lived and probably mature in their second or third year. The study aimed to examine their habitat use and competitive interactions.

Traps were set for 12 3-day sessions over 1995–1996, but some sessions yielded very few captures because skinks were inactive, and some sessions were incomplete for logistical reasons. The data are from sessions 6 and 7 in late spring (17–20 October 1995 and 14–17 November 1995). Traps were cleared daily; the few skinks present when traps were closed on the morning of the fourth day are treated as Day 3 captures. Individuals were marked uniquely by clipping one toe on each foot. Natural toe loss caused some problems with long-term identification; captures were dropped from the dataset when identity was uncertain. Released animals were occasionally recaptured in a different trap on the same day; these records were also discarded.

The data are provided as two two-session capthist objects ‘infraCH’ and ‘lineoCH’. Also included is ‘LStraps’, the traps object with the coordinates and covariates of the trap sites (these data are also embedded in each of the capthist objects). Pitfall traps are multi-catch traps so detector(LStraps) = ‘multi’.

Habitat data for each trap site are included as a dataframe of trap covariates in LStraps. Ground cover and vegetation were recorded for a 1-m radius plot at each trap site. The dataframe also gives the total number of captures of each species by site on 31 days between April 1995 and March 1996, and the maximum potential annual solar radiation calculated from slope and aspect (Frank and Lee 1966). Each site was assigned to a habitat class by fuzzy clustering (Kaufman and Rousseauw 1990; package cluster) of a distance matrix using the ground cover, vegetation and solar radiation variables. Sites in class 1 were open with bare ground or low-canopy vegetation including the heath-like *Leucopogon fraseri* and grasses; sites in class 2 had more-closed vegetation, lacking
*Leucopogon fraseri* and with a higher canopy that often included *Coriaria arborea*. Site variables are listed with definitions in the attribute `habitat.variables` of `LStraps` (see Examples).

smooths

Smooth Terms in SECR Models

Description

From version 2.9.0, the model formulae provided to `secr.fit` may include smooth terms as specified for the `mgcv` function ‘gam’, with some restrictions. Smooth terms may be used for both density and detection parameters.

Details

The specification of smooth terms is explained in `formula.gam`. Only a subset of options are relevant to ‘secr’. Penalized splines are not available. The smooth function may be ‘s’ or ‘te’.

The ‘wiggliness’ of the curve is controlled by the argument k, which in this implementation is set by the user. The argument ‘fx’ should be set to TRUE.

See also the example in `secr-densitysurfaces.pdf`.

Background

Regression splines are a very flexible way to represent non-linear responses in generalized additive models (e.g., `mgcv`, Wood 2006). Borchers and Kidney (2014) have shown how they may be used to model 2-dimensional trend in density in `secrgam`, an R package that extends `secr`. Their approach is to use `mgcv` to construct regression spline basis functions from mask x- and y-coordinates, and possibly additional mask covariates, and to pass these as covariates to `secr`. The idea of using `mgcv` to construct the basis functions is applied within `secr` from version 2.9.

Smooth semi-parametric responses are also useful for modelling variation in detection parameters such as g0 and sigma over time, or in response to individual or detector-level covariates, when (1) a linear or other parametric response is arbitrary or implausible, and (2) sampling spans a range of times or levels of the covariate(s).

For a concrete example, consider a population sampled monthly for a year (i.e., 12 ‘sessions’). If home range size varies seasonally then the parameter sigma may vary in a more-or-less sinusoidal fashion. A linear trend is obviously inadequate, and a quadratic is not much better. However, a sine curve is hard to fit (we would need to estimate its phase, amplitude, mean and spatial scale) and assumes the increase and decrease phases are equally steep. An extreme solution is to treat month as a factor and estimate a separate parameter for each level (month). A smooth (semi-parametric) curve may capture the main features of seasonal variation with fewer parameters.
Warning

This implementation of smooth models results in large fitted objects, on account of the need to store setup information from \texttt{mgcv}. It is also vulnerable to future changes in \texttt{mgcv}.

Expect that the implementation will change in later versions of \texttt{secr}, and that smooth models fitted in this version will not necessarily be compatible with \texttt{predict} and \texttt{predictDsurface} in later versions.

Note

Setting the intercept of a smooth to zero is not a canned option in \texttt{mgcv}, and is not offered in \texttt{secr}. It may be achieved by placing a knot at zero and hacking the matrix of basis functions to drop the corresponding column, plus some more jiggling.

Examples

```r
## Not run:
## smooth density surface
possum.model.sxy <- secr.fit(possumCH, mask = possummask,
  model = D ~ s(x,y, k = 6, fx = TRUE), trace = FALSE)
fittedsurface <- predictDsurface(possum.model.sxy)
par(mar = c(1,1,1,6))
plot(fittedsurface)
plot(fittedsurface, plottype = 'contour', add = TRUE)
par(mar = c(5,4,4,2) + 0.1) ## reset to default

## Now try smooth on g0
## For the smooth we use 'Session' which is coded numerically (0:4)
## rather than the factor 'session' (''2005', '2006', '2007', '2008',
## '2009')
ovenbird.model.g0 <- secr.fit(ovenCH, mask = ovenmask,
  model = g0 ~ session, trace = FALSE)
ovenbird.model.sg0 <- secr.fit(ovenCH, mask = ovenmask,
  model = g0 ~ s(Session, k = 3, fx = TRUE), trace = FALSE)
AIC(ovenbird.model.g0, ovenbird.model.sg0)
```
## Or over occasions within a session...

```r
fit.sT3 <- secr.fit(captdata, model = g0 ~ s(T, k = 3, fx = TRUE),
                    trace = FALSE)
pred <- predict(fit.sT3, newdata = data.frame(T = 0:4))
plot(sapply(pred, '[', 'g0', 'estimate'))
```

## End(Not run)

---

### Slice Transect Into Shorter Sections

#### Description

This function splits the transects in a ‘transect’ or ‘transectX’ traps object into multiple shorter sections. The function may also be applied directly to a capthist object based on transect data. This makes it easy to convert detection data collected along linear transects to point detection data (see Example).

#### Usage

```r
snip(object, from = 0, by = 1000, length.out = NULL, keep.incomplete = TRUE, tol = 0.01)
```

#### Arguments

- `object`: secr ‘traps’ or ‘capthist’ object based on transects
- `from`: numeric starting position (m)
- `by`: numeric length of new transects (m)
- `length.out`: numeric number of new transects, as alternative to ‘by’
- `keep.incomplete`: logical; if TRUE then initial or terminal sections of each original transect that are less than ‘by’ will be retained in the output
- `tol`: numeric tolerance for xyontransect (capthist only)

#### Details

If a positive `length.out` is specified, `by` will be computed as `(transectlength(object) - from) / length.out`.

#### Value

A ‘traps’ or ‘capthist’ object, according to the input. If `keep.incomplete == FALSE` animals and detections from the
See Also

transectlength, discretize

Examples

```r
x <- seq(0, 4*pi, length = 41)
temptrans <- make.transect(x = x*100, y = sin(x)*300)
plot (snip(temptrans, by = 200), markvertices = 1)

## Not run:
## simulate some captures
tempcapt <- sim.capthist(temptrans, popn = list(D = 2,
    buffer = 300), detectfn = 'HHN', binomN = 0,
    detectpar = list(lambda0 = 0.5, sigma = 50))

## snip capture histories
tempCH <- snip(tempcapt, by = 20)

## collapse from 'transect' to 'count', discarding location within transects
tempCH <- reduce(tempCH, outputdetector = "count")

## fit secr model and examine H-T estimates of density
## fails with detectfn = 'HN'
fit <- secr.fit(tempCH, buffer = 300, CL = TRUE, detectfn = 'HHN', trace = FALSE)
derived(fit)

## also, may split an existing transect into equal lengths
## same result:
plot(snip(temptrans, by = transectlength(temptrans)/10),
    markvertices = 1)
plot(snip(temptrans, length.out = 10), markvertices = 1)

## End(Not run)
```

---

**sort.capthist**

**Sort Rows of capthist or mask Object**

**Description**

Rows are sorted by fields in covariates or by a provided sort key of length equal to the number of rows.
Usage

```r
## S3 method for class 'capthist'
sort(x, decreasing = FALSE, by = "", byrowname = TRUE, ...)

## S3 method for class 'mask'
sort(x, decreasing = FALSE, by = "", byrowname = TRUE, ...)
```

Arguments

- `x` capthist object
- `decreasing` logical. Should the sort be increasing or decreasing?
- `by` character vector (names of covariates) or data frame whose columns will be used as sort keys
- `byrowname` logical. Should row name be used as a final sort key?
- `...` other arguments (not used)

Details

For multi-session capthist objects only the named covariate form is suitable as the number of rows varies between sessions.

If requested, rows are sorted by rowname within `by`. The effect of the default is to sort by rowname.

The attribute marking points of a mask object is removed if present, as it is no longer meaningful.

Value

capthist or mask object with sorted rows; any relevant attributes are also sorted (covariates, signal, xy)

See Also

capthist

Examples

```r
sort(ovenCH, by = "Sex")
covariates(ovenCH)["2005"]
covariates(sort(ovenCH, by = "Sex"))["2005"]
```
## spelling

**Detector or Mask Spacing**

### Description

Extract or replace the spacing attribute of a detector array or mask.

### Usage

```r
spacing(object, ...)  
spacing(object) <- value
```

```r  
## S3 method for class 'traps'  
spacing(object, ..., recalculate = FALSE)
## S3 method for class 'mask'  
spacing(object, ..., recalculate = FALSE)
```

### Arguments

- **object**: object with ‘spacing’ attribute e.g. traps
- **value**: numeric value for spacing
- **...**: other arguments (not used)
- **recalculate**: logical; if TRUE compute average spacing afresh

### Details

The ‘spacing’ attribute of a detector array is the average distance from one detector to the nearest other detector.

The attribute was not always set by `make.grid()` and `read.traps()` in versions of `secr` before 1.5.0. If the attribute is found to be NULL then `spacing` will compute it on the fly.

### Value

scalar numeric value of mean spacing, or a vector if `object` has multiple sessions

### See Also

- `traps`

### Examples

```r  
temptrap <- make.grid(nx = 6, ny = 8)  
spacing(temptrap)
```
Description

A list of ways to make secr.fit run faster.

Use an appropriate mask

Check the extent and spacing of the habitat mask that you are using. Execution time is roughly proportional to the number of mask points (nrow(mymask)). Default settings can lead to very large masks for detector arrays that are elongated ‘north-south’ because the number of points in the east-west direction is fixed. Compare results with a much sparser mask (e.g., nx = 32 instead of nx = 64).

Use conditional likelihood

If you don’t need to model variation in density over space or time then consider maximizing the conditional likelihood in secr.fit (CL = TRUE). This reduces the complexity of the optimization problem, especially where there are several sessions and you want session-specific density estimates (by default, derived() returns a separate estimate for each session even if the detection parameters are constant across sessions).

Model selection

Do you really need to fit all those complex models? Chasing down small decrements in AIC is so last-century. Remember that detection parameters are mostly nuisance parameters, and models with big differences in AIC may barely differ in their density estimates. This is a good topic for further research - we seem to need a ‘focussed information criterion’ (Claeskens and Hjort 2008) to discern the differences that matter. Be aware of the effects that can really make a difference: learned responses (b, bk etc.) and massive unmodelled heterogeneity.

Use score.test() to compare nested models. At each stage this requires only the more simple model to have been fitted in full; further processing is required to obtain a numerical estimate of the gradient of the likelihood surface for the more complex model, but this is much faster than maximizing the likelihood. The tradeoff is that the score test is only approximate, and you may want to later verify the results using a full AIC comparison.

Break problem down

Suppose you are fitting models to multiple separate datasets that fit the general description of ‘sessions’. If you are fitting separate detection parameters to each session (i.e., you do not need to pool detection information), and you are not modelling trend in density across sessions, then it is much quicker to fit each session separately than to try to do it all at once. See Examples.

Mash replicated clusters of detectors

If your detectors are arranged in similar clusters (e.g., small square grids) then try the function mash.
Reduce sparse ‘proximity’ data to ‘multi’

Full data from ‘proximity’ detectors has dimensions n x S x K (n is number of individuals, S is number of occasions, K is number of traps). If the data are sparse (i.e. multiple detections of an individual on one occasion are rare) then it is efficient to treat proximity data as multi-catch data (dimension n x S, maximum of one detection per occasion). Use reduce(proxCH, outputdetector = "multi")

Use multiple cores when applicable

Most computers these days have multiple processors and these will be used by secr if the user sets ncores greater than one in secr.fit, sim.secr and some other functions. If ncores = NULL then the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS is used (see setNumThreads).

Functions par.secr.fit, par.derived, and par.secr.fit are an alternative way to take advantage of multiple cores when fitting several models.

Avoid covariates with many levels

Categorical (factor) covariates with many levels and continuous covariates that take many values are not handled efficiently in secr.fit, and can dramatically slow down analyses and increase memory requirements.

Set appropriate typsize

Setting typsize manually in the call of ‘secr.fit’ can speed up fitting when magnitudes on the link scale are very different (for example, when an identity link is used for density and density is very small or very large).

Simulations

Model fitting is not needed to assess power. The precision of estimates from secr.fit can be predicted without laboriously fitting models to simulated datasets. Just use method = "none" to obtain the asymptotic variance at the known parameter values for which data have been simulated (e.g. with sim.capthist()).

Suppress computation of standard errors by derived(). For a model fitted by conditional likelihood (CL = TRUE) the subsequent computation of derived density estimates can take appreciable time. If variances are not needed (e.g., when the aim is to predict the bias of the estimator across a large number of simulations) it is efficient to set se.D = FALSE in derived().

It is tempting to save a list with the entire ‘secr’ object from each simulated fit, and to later extract summary statistics as needed. Be aware that with large simulations the overheads associated with storage of the list can become very large. The solution is to anticipate the summary statistics you will want and save only these.

## End(Not run)
```

---

**stoatDNA**

**Stoat DNA Data**

**Description**

Data of A. E. Byrom from a study of stoats (*Mustela erminea*) in New Zealand. Individuals were identified from DNA in hair samples.

**Usage**

```r
stoatCH
stoat.model.HN
stoat.model.EX
```

**Details**

The data are from a pilot study of stoats in red beech (*Nothofagus fusca*) forest in the Matakitaki Valley, South Island, New Zealand. Sticky hair-sampling tubes (*n* = 94) were placed on a 3-km x 3-km grid with 500-m spacing between lines and 250-m spacing along lines. Tubes were baited with rabbit meat and checked daily for 7 days, starting on 15 December 2001. Stoat hair samples were
identified to individual using DNA microsatellites amplified by PCR from follicular tissue (Gleeson et al. 2010). Six loci were amplified and the mean number of alleles was 7.3 per locus. Not all loci could be amplified in 27% of samples. A total of 40 hair samples were collected (Gleeson et al. 2010), but only 30 appear in this dataset; the rest presumably did not yield sufficient DNA for genotyping.

The data are provided as a single-session capthist object ‘stoatCH’. Hair tubes are ‘proximity’ detectors which allow an individual to be detected at multiple detectors on one occasion (day), but there are no multiple detections in this dataset and for historical reasons the data are provided as detector type ‘multi’. Two pre-fitted models are included: stoat.model.HN and stoat.model.EX.

Object Description
stoatCH capthist object
stoat.model.HN fitted secr model – null, halfnormal detection function
stoat.model.EX fitted secr model – null, exponential detection function

Note

The log-likelihood values reported for these data by secr.fit differ by a constant from those published by Efford et al. (2009) because the earlier version of DENSITY used in that analysis did not include the multinomial coefficient, which in this case is log(20!) or about +42.336. The previous analysis also used a coarser habitat mask than the default in secr (32 x 32 rather than 64 x 64) and this slightly alters the log-likelihood and ΔAIC values.

Fitting the hazard-rate detection function previously required the shape parameter z (or b) to be fixed, but the model can be fitted in secr without fixing z. However, the hazard rate function can cause problems owing to its long tail, and it is not recommended. The check on the buffer width, usually applied automatically on completion of secr.fit, causes an error and must be suppressed with biasLimit = NA (see Examples).

Gleeson et al. (2010) address the question of whether there is enough variability at the sampled microsatellite loci to distinguish individuals. The reference to 98 sampling sites in that paper is a minor error (A. E. Byrom pers. comm.).

strip.legend  Colour Strip Legend

Description

This function is used with shaded plots to display a legend.

Usage

strip.legend(xy, legend, col, legendtype = c("breaks", "intervals", "other"),
             tileborder = NA, height = 0.5, width = 0.06, inset = 0.06, text.offset = 0.02,
             text.cex = 0.9, xpd = TRUE, scale = 1, title = "", box = NA, box.col = par()$bg)
Arguments

- **xy**: location of legend (see Details)
- **legend**: character vector (see Details)
- **col**: vector of colour values
- **legendtype**: character
- **tileborder**: colour of lines around each tile in the colour strip. Use NA for none.
- **height**: height of colour strip as a fraction of the plot dimensions
- **width**: width of colour strip as a fraction of the plot dimensions
- **inset**: spacing between legend and outside plot boundary, as a fraction of the plot dimensions
- **text.offset**: spacing between colour strip and text, as a fraction of the plot dimensions
- **text.cex**: size of text font
- **xpd**: logical, if TRUE the legend will use the margins of the plot
- **scale**: numeric; each value x will be displayed as scale * x
- **title**: text displayed above legend
- **box**: colour of frame, if framed, otherwise NA
- **box.col**: colour of background, if framed, otherwise ignored

Details

The location of the legend is determined by **xy** which may be one of the character values "topright", "topleft", "bottomright", "bottomleft", "right", "left", or the x-y coordinates (in user units) of the top-left corner of the colour strip. Coordinates may be given as a vector or a list, and the output from **locator(1)** is suitable.

For more on colours, see notes in **plot.mask** and **colors** and **terrain.colors**

If **legendtype** = 'breaks' then labels are placed at the class boundaries; otherwise, the labels are centred vertically. If **legendtype** = 'breaks' or **legendtype** = 'intervals' then numeric values are extracted from the input, otherwise the text strings in **legend** are used as provided.

The legend itself may be provided as a vector of values or as the class labels output from **plot.mask**. Class labels are generated by **cut** in the form '{0,20]', '{20,40]', etc. These are parsed to construct either breaks (0,20,40,...) or intervals ('0-20', '20-40',...) as requested in the **legendtype** argument.

**box** may also be TRUE/FALSE; if TRUE the foreground colour is used **par()$fg**.

Value

Invisibly returns a vector of user coordinates for the left, right, bottom and top of the colour strip.

Note

From **secr** 2.9.0, the default behaviour of **plot.mask** is to call **strip.legend** to display a legend in the top right of the plot, labeled at breaks.
subset.capthist

Subset or Split capthist Object

Description
Create a new capthist object or list of objects by selecting rows (individuals), columns (occasions) and traps from an existing capthist object.

Usage

```r
# S3 method for class 'capthist'
subset(x, subset = NULL, occasions = NULL, traps = NULL,
sessions = NULL, cutval = NULL, dropnullCH = TRUE, dropnullocc = FALSE,
dropunused = TRUE, droplowsignals = TRUE, dropNAsignals = FALSE,
cutabssignal = TRUE, renumber = FALSE, ...)
```

```r
# S3 method for class 'capthist'
split(x, f, drop = FALSE, prefix = "S", bytrap = FALSE,
byoccasion = FALSE, ...)
```
Arguments

- **x** object of class `capthist`
- **subset** vector of subscripts to select rows (individuals) (see Details for variations)
- **occasions** vector of subscripts to select columns (occasions)
- **traps** vector of subscripts to select detectors (traps)
- **sessions** vector of subscripts to select sessions
- **cutval** new threshold for signal strength
- **dropnullCH** logical for whether null (all-zero) capture histories should be dropped
- **dropnullocc** logical for whether occasions with no detections should be dropped
- **dropunused** logical for whether never-used detectors should be dropped
- **droplowsignals** logical for whether `cutval` should be applied at each microphone rather than to sound as a whole
- **dropNAsignals** logical for whether detections with missing signal should be dropped
- **cutabssignal** logical for whether to apply `cutval` to absolute signal strength or the difference between signal and noise
- **renumber** logical for whether row.names should be replaced with sequence number in new `capthist`
- **f** factor or object that may be coerced to a factor
- **drop** logical indicating if levels that do not occur should be dropped (if f is a factor)
- **prefix** a character prefix to be used for component names when values of f are numeric
- **bytrap** logical; if TRUE then each level of f identifies traps to include
- **byoccasion** logical; if TRUE then each level of f identifies occasions to include
- **...** other arguments passed to `subset.capthist` (split.capthist) or to optional subset function (`subset.capthist`)

Details

Subscript vectors may be either logical- (length equal to the relevant dimension of x), character- or integer-valued. Subsetting is applied to attributes (e.g. covariates, traps) as appropriate. The default action is to include all animals, occasions, and detectors if the relevant argument is omitted. When traps is provided, detections at other detectors are set to zero, as if the detector had not been used, and the corresponding rows are removed from traps. If the detector type is ‘proximity’ then selecting traps also reduces the third dimension of the capthist array.

`split` generates a list in which each component is a capthist object. Each component corresponds to a level of f. Multi-session capthists are accepted in `secr` >= 4.4.0; f should then be a list of factors with one component per session and the same levels in all.

To combine (pool) occasions use `reduce.capthist`. There is no equivalent of `unlist` for lists of capthist objects.

The effect of `droplowsignals = FALSE` is to retain below-threshold measurements of signal strength on all channels (microphones) as long as the signal is above `cutval` on at least one. In this case all retained sounds are treated as detected on all microphones. This fails when signals are already missing on some channels.

Subsetting is awkward with multi-session input when the criterion is an individual covariate. See the Examples for one way this can be tackled.
subset.capthist

Value

capthist object with the requested subset of observations, or a list of such objects (i.e., a multi-session capthist object). List input results in list output, except when a single session is selected.

See Also
capthist, rbind.capthist, reduce.capthist

## Split out captures on alternate rows of a grid

tempcapt5 <- split(captdata, f = rep(1:2, 50), bytrap = TRUE)
summary(tempcapt5)

## Divide one session into two by occasion

tempcapt6 <- split(captdata, f = factor(c(1,1,2,2,2)), byoccasion = TRUE)
summary(tempcapt6)

## Applying a covariate criterion across all sessions of a
## multi-session capthist object e.g. selecting male ovenbirds from the
## 2005--2009 ovenCH dataset. We include a restriction on occasions
## to demonstrate the use of 'MoreArgs'. Note that mapply() creates a
## list, and the class of the output must be restored manually.

ovenCH.males <- mapply(subset, ovenCH,
   subset = lapply(ovenCH, function(x) covariates(x)$Sex == "M"),
   MoreArgs = list(occasions = 1:5))
class(ovenCH.males) <- class(ovenCH)
summary(ovenCH.males, terse = TRUE)

## A simpler approach using a function to define subset
subsetfn <- function(x, sex) covariates(x)$Sex == sex
ovenCH.males <- subset(ovenCH, subset = subsetfn, sex = "M")
summary(ovenCH.males, terse = TRUE)

subset.mask

## S3 method for class 'mask'
subset(x, subset, ...)

## S3 method for class 'mask'
split(x, f, drop = FALSE, clusters = NULL, ...)

## S3 method for class 'mask'
rbind(...)

Arguments

x          mask object
subset     numeric or logical vector to select rows of mask
f          factor or object that may be coerced to a factor
drop       logical indicating if levels that do not occur should be dropped (if f is a factor)
clusters   list of traps objects, each defining a cluster (alternative to f)
...         two or more mask objects (rbind only)

Details

The subscripts in subset may be of type integer, character or logical as described in Extract.

The split method may use either a factor f with one value for each row or a list of clusters, each a traps object. The output mask corresponding to each cluster is the subset of the original mask points that lie within buffer of a trap within the cluster; buffer is computed as the maximum distance between a mask point in x and any detector in clusters. Sub-masks specified with clusters may overlap.

Covariates are ignored by rbind.mask.
Value

For `subset`, an object of class ‘mask’ with only the requested subset of rows and ‘type’ attribute set to ‘subset’.

For `split`, a list of mask objects.

For `rbind`, an object of class ‘mask’ with all unique rows from the masks in . . . , and ‘type’ attribute set to ‘rbind’.

Warning

The spacing attribute is carried over from the input (it is not updated automatically). In the case of very sparse masks (i.e. those with isolated points) this may lead to an unexpected value for this attribute. (Automatic updating requires excessive computation time and/or memory for very large masks).

`mask`

Examples

tempmask <- make.mask(make.grid())
OK <- (tempmask$x + tempmask$y) > 100
tempmask <- subset(tempmask, subset = OK)
plot(tempmask)

subset.popn  Subset popn Object

Description

Retain selected rows of a popn object.

Usage

```r
## S3 method for class 'popn'
subset(x, subset = NULL, sessions = NULL, poly = NULL,
       poly.habitat = TRUE, keep.poly = TRUE, renumber = FALSE, ...)
```

Arguments

- `x`  popn object
- `subset`  vector to subscript the rows of `x`
- `sessions`  vector to subscript sessions if `x` is a multi-session population
- `poly`  bounding polygon (see Details)
- `poly.habitat`  logical for whether `poly` represents habitat or its inverse (non-habitat)
subset.traps

**Subset traps Object**

**Description**

Retain selected rows of a traps object.

**Usage**

```r
## S3 method for class 'traps'
subset(x, subset = NULL, occasions = NULL, ...)
## S3 method for class 'traps'
split(x, f, drop = FALSE, prefix = "S", byoccasion = FALSE, ...)
```

**Details**

The subscripts in `subset` may be of type integer, character or logical as described in `Extract`. By default, all rows are retained.

In the case of a multi-session `popn` object (a list of populations), `subset` may be a list with one component for the subscripts in each new session.

If `poly` is specified, points outside `poly` are dropped. `poly` may be one of the types described in `boundarytoSF`.

**Value**

An object of class `popn` with only the requested subset of rows. Subsetting is applied to the covariates attribute if this is present. Attributes ‘Ndist’ and ‘model2D’ are set to NULL.

**See Also**

`popn`

**Examples**

```r
temppop <- sim.popn(D = 10, expand.grid(x = c(0,100), y = c(0,100)), buffer = 50)
## 50% binomial sample of simulated population
temppops <- subset(temppop, runif(nrow(temppop)) < 0.5)
plot(temppop)
plot(temppops, add = TRUE, pch = 16)
```
Arguments

- **x**: traps object
- **subset**: vector to subscript the rows of **x**
- **occasions**: vector to subscript columns in `usage(x)`
- ... arguments passed to other functions or to optional subset function (subset.traps)
- **f**: factor or object that may be coerced to a factor
- **drop**: logical indicating if levels that do not occur should be dropped (if **f** is a factor)
- **prefix**: a character prefix to be used for component names when values of **f** are numeric
- **byoccasion**: logical; if TRUE then **f** is used to split occasions

Details

The subscripts in `subset` may be of type integer, character or logical as described in `Extract`. By default, all rows are retained.

In the case of ‘polygon’ and ‘transect’ detectors, subsetting is done at the level of whole polygons or transects. `subset` should therefore have the same length as `levels(polyID(x))` or `levels(transectID(x))`.

`split` generates a list in which each component is a `traps` object. Each component corresponds to a level of **f**. The argument **x** of `split` cannot be a list (i.e. **x** must be a single-session `traps` object).

If the levels of **f** are numeric, from version 2.10.3 a leading zero is inserted in the names of the output list to maintain the sort order.

Value

An object of class `traps` with only the requested subset of rows. Subsetting is applied to `usage` and `covariates` attributes if these are present.

Splitting with `byoccasion = TRUE` produces a list of `traps` objects, each with usage codes for a subset of occasions. Traps not used on any occasion within a session are automatically dropped from that session.

See Also

- `traps`, `rbind.traps`

Examples

```r
## odd-numbered traps only, using modulo operator
temptrap <- make.grid(nx = 7, ny = 7)
t2 <- subset(temptrap, as.logical(1:nrow(temptrap) %% 2))
plot(t2)

## this works also for even number of rows, but must change 'outer' call
temptrap <- make.grid(nx = 8, ny = 8)
t3 <- subset(temptrap, !as.logical(outer(1:8,1:8,'+')%%2))
plot(t3)
```
suggest.buffer  

Mask Buffer Width

Description

Determines a suitable buffer width for an integration mask. The ‘buffer’ in question defines a concave polygon around a detector array constructed using make.mask with type = “trapbuffer”. The method relies on an approximation to the bias of maximum likelihood density estimates (M. Efford unpubl).

Usage

suggest.buffer(object, detectfn = NULL, detectpar = NULL, noccasions = NULL, ignoreusage = FALSE, ncores = NULL, RBtarget = 0.001, interval = NULL, binomN = NULL, ...)

bias.D (buffer, traps, detectfn, detectpar, noccasions, binomN = NULL, control = NULL)

Arguments

object single-session ‘secr’, ‘traps’ or ‘capthist’ object
detectfn integer code or character string for shape of detection function 0 = halfnormal etc. – see detectfn
detectpar list of values for named parameters of detection function – see detectpar
noccasions number of sampling occasions
ignoreusage logical for whether to discard usage information from traps(capthist)
ncores integer number of threads to use for parallel processing
RBtarget numeric target for relative bias of density estimate
interval a vector containing the end-points of the interval to be searched
binomN integer code for distribution of counts (see secr.fit)
... other argument(s) passed to bias.D
buffer vector of buffer widths
traps ‘traps’ object
control list of mostly obscure numerical settings (see Details)

Details

The basic input style of suggest.buffer uses a ‘traps’ object and a detection model specified by ‘detectpar’, ‘detectfn’ and ‘noccasions’, plus a target relative bias (RB). A numerical search is conducted for the buffer width that is predicted to deliver the requested RB. If interval is omitted it defaults to (1, 100S) where S is the spatial scale of the detection function (usually detectpar$sigma).
suggest.buffer

An error is reported if the required buffer width is not within interval. This often happens with heavy-tailed detection functions (e.g., hazard-rate): choose another function, a larger RBtarget or a wider interval.

Setting ncores = NULL uses the existing value from the environment variable RCPP_PARALLEL_NUM_THREADS (see setNumThreads).

Convenient alternative input styles are –

- secr object containing a fitted model. Values of ‘traps’, ‘detectpar’, ‘detectfn’ and ‘noccasions’ are extracted from object and any values supplied for these arguments are ignored.
- capthist object containing raw data. If detectpar is not supplied then autoini is used to get ‘quick and dirty’ values of $g_0$ and sigma for a halfnormal detection function. noccasions is ignored. autoini tends to underestimate sigma, and the resulting buffer also tends to be too small.

bias.D is called internally by suggest.buffer.

Value

suggest.buffer returns a scalar value for the suggested buffer width in metres, or a vector of such values in the case of a multi-session object.

bias.D returns a dataframe with columns buffer and RB.D (approximate bias of density estimate using finite buffer width, relative to estimate with infinite buffer).

Note

The algorithm in bias.D uses one-dimensional numerical integration of a polar approximation to site-specific detection probability. This uses a further 3-part linear approximation for the length of contours of distance-to-nearest-detector ($r$) as a function of $r$.

The approximation seems to work well for a compact detector array, but it should not be taken as an estimate of the bias for any other purpose: do not report RB.D as "the relative bias of the density estimate". RB.D addresses only the effect of using a finite buffer. The effect of buffer width on final estimates should be checked with mask.check.

The default buffer type in make.mask, and hence in secr.fit, is ‘traprect’, not ‘trapbuffer’, but a buffer width that is adequate for ‘trapbuffer’ is always adequate for ‘traprect’.

control contains various settings of little interest to the user.

The potential components of control are –

- method = 1 code for method of modelling $p(X)$ as a function of buffer ($q(r)$)
- bfactor = 20 $q(r)$ vs $p(X)$ calibration mask buffer width in multiples of trap spacing
- masksample = 1000 maximum number of points sampled from calibration mask
- spline.df = 10 effective degrees of freedom for smooth.spline
- ncores = NULL integer number of cores

## compare detection histories and fitted model as input
suggest.buffer(captdata)
suggest.buffer(secrdemo.0)

## End(Not run)
```

summary.capthist

**Summarise Detections**

**Description**
Concise description of capthist object.

**Usage**

```
## S3 method for class 'capthist'
summary(object, terse = FALSE, moves = FALSE, tpa = FALSE, ...)

## S3 method for class 'summary.capthist'
print(x, ...)

counts(CHlist, counts = "M(t+1)")
```
Arguments

- **object**: `capthist` object
- **terse**: logical; if TRUE return only summary counts
- **moves**: logical; if TRUE then summary includes detected movements
- **tpa**: logical; if TRUE then summary includes number of detectors per animal
- **x**: `summary.capthist` object
- **...**: arguments passed to other functions
- **CHlist**: `capthist` object, especially a multi-session object
- **counts**: character vector of count names

Details

These counts are reported by `summary.capthist`

- **n**: number of individuals detected on each occasion
- **u**: number of individuals detected for the first time on each occasion
- **f**: number of individuals detected exactly f times
- **M(t+1)**: cumulative number of individuals detected
- **losses**: number of individuals reported as not released on each occasion
- **detections**: number of detections, including within-occasion ‘recaptures’
- **traps visited**: number of detectors at which at least one detection was recorded
- **traps set**: number of detectors, excluding any ‘not set’ in usage attribute of `traps` attribute

The last two rows are dropped if the data are nonspatial (object has no traps attribute).

Movements are as reported by `moves`. When **terse = TRUE** the number of non-zero moves is reported. The temporal sequence of detections at ‘proximity’ and ‘count’ detectors is not recorded in the `capthist` object, so the movement statistics are not to be taken too seriously. The problem is minimised when detections are sparse (seldom more than one per animal per occasion), and does not occur with ‘single’ or ‘multi’ detectors.

The ‘tpa’ option provides the frequency distribution of detectors per animal. When **terse = TRUE** the number of animals at >= 2 detectors is reported (‘Animal2’).

**counts** may be used to return the specified counts in a compact session x occasion table. If more than one count is named then a list is returned with one component for each type of count.

Value

From `summary.capthist`, an object of class `summary.capthist`, a list with at least these components

- **detector**: detector type (“single”, “multi”, “proximity” etc.)
- **ndetector**: number of detectors
- **xrange**: range of x coordinates of detectors
- **yrange**: range of y coordinates of detectors
summary.mask

Concise summary of a mask object.

Usage

```r
## S3 method for class 'mask'
summary(object, ...)
## S3 method for class 'summary.mask'
print(x, ...)
```

Arguments

- `object`: mask object
- `x`: summary.mask object
- `...`: other arguments (not used)

Details

The bounding box is the smallest rectangular area with edges parallel to the x- and y-axes that contains all points and their associated grid cells. A print method is provided for objects of class summary.mask.
Value

Object of class ‘summary.mask’, a list with components

defector character string for detector type ("single","multi","proximity")
type mask type ("traprect","trapbuffer","pdot","polygon","user","subset")
nmaskpoints number of points in mask
xrange range of x coordinates
yrange range of y coordinates
meanSD dataframe with mean and SD of x, y, and each covariate
spacing nominal spacing of points
cellarea area (ha) of grid cell associated with each point
bounding box dataframe with x-y coordinates for vertices of bounding box
covar summary of each covariate

mask

Examples

tempmask <- make.mask(make.grid())
## left to right gradient
covariates (tempmask) <- data.frame(x = tempmask$x)
summary(tempmask)

summary.popn Summarise Simulated Population

Description

Concise summary of a popn object.

Usage

## S3 method for class 'popn'
summary(object, collapse = FALSE, ...)
## S3 method for class 'summary.popn'
print(x, ...)

Arguments

object popn object
collapse logical; if TRUE multi-session popn objects are treated as a single open popula-
tion
x summary.popn object
... other arguments (not used)
Details

By default each component of a multisession object is summarised separately. If collapse = TRUE then turnover and movements are collated across sessions, matching individuals by rownames.

Value

For summary.popn, an object of class ‘summary.popn’ with various components. For a multisession object and collapse = TRUE the descriptors include the numbers of new individuals (recruits) and lost individuals (deaths), and matrices showing the status of each animal in each session (‘status’ codes 0 not recruited yet; 1 alive; -1 dead) and movement from previous session if alive then (‘movements’).

See Also

sim.popn

Examples

grid <- make.grid(8,8)
turnover <- list(phi = 0.8, lambda = 1)
pop <- sim.popn(Nbuffer = 200, core = grid, buffer = 200, Ndist = 'fixed',
    nsessions = 5, details = turnover)
summary(pop, collapse = TRUE)
Details

When object includes both categorical (factor) covariates and usage, usage is tabulated for each level of the covariates.

Computation of spacing (mean distance to nearest trap) is slow and may hit a memory limit when there are many traps. In this case, turn off the computation with `getspacing = FALSE`.

Value

An object of class `summary.traps`, a list with elements

- `detector`  
  - `detector` type ("single", "multi", "proximity" etc.)
- `ndetector`  
  - number of detectors
- `xrange`  
  - range of x coordinates
- `yrange`  
  - range of y coordinates
- `spacing`  
  - mean distance from each trap to nearest other trap
- `usage`  
  - table of usage by occasion
- `covar`  
  - summary of covariates

See Also

- `print.traps`

Examples

```r
demo.traps <- make.grid()
summary(demo.traps)  ## uses print method for summary.traps object
```

---

**timevaryingcov**  

**Time-varying Covariates**

Description

Extract or replace time varying covariates

Usage

```r
timevaryingcov(object, ...)  
timevaryingcov(object) <- value
```

Arguments

<table>
<thead>
<tr>
<th>argument</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>object</code></td>
<td>an object of class <code>traps</code> or <code>capthist</code></td>
</tr>
<tr>
<td><code>value</code></td>
<td>a list of named vectors</td>
</tr>
<tr>
<td><code>...</code></td>
<td>other arguments (not used)</td>
</tr>
</tbody>
</table>
Details

The timevaryingcov attribute is a list of one or more named vectors. Each vector identifies a subset of columns of covariates(object), one for each occasion. If character values are used they should correspond to covariate names.

In secr models, time-varying covariates are restricted to traps objects. Time-varying (session-specific) individual covariates may be used in openCR. The following remarks apply to time-varying traps covariates.

The name of the vector may be used in a model formula; when the model is fitted, the value of the trap covariate on a particular occasion is retrieved from the column indexed by the vector.

For replacement, if object already has a usage attribute, the length of each vector in value must match exactly the number of columns in usage(object).

When converting a multi-session capthist object into a robust-design “single-session” object with function join the argument ‘timevaryingcov’ is used to collate covariate values across sessions in a form suitable for inclusion in openCR models (see join).

Value
timevaryingcov(object) returns the timevaryingcov attribute of object (may be NULL).

Note

It is usually better to model varying effort directly, via the usage attribute (see secr-varyingeffort.pdf).

Models for data from detectors of type ‘multi’, ‘polygonX’ or ‘transectX’ take much longer to fit when detector covariates of any sort are used.

Time-varying covariates are not available with the (default) ‘fastproximity’ option.

See secr-varyingeffort.pdf for input of detector covariates from a file.

join

Examples

```r
# make a trapping grid with simple covariates
temptrap <- make.grid(nx = 6, ny = 8, detector = "multi")
covariates (temptrap) <- data.frame(matrix(
  c(rep(1,48*3),rep(2,48*2)), ncol = 5))
head(covariates (temptrap))

# identify columns 1-5 as daily covariates
timevaryingcov(temptrap) <- list(blockt = 1:5)
timevaryingcov(temptrap)

## Not run:

# default density = 5/ha, no occurrences = 5
CH <- sim.capthist(temptrap, detectpar = list(g0 = c(0.15, 0.15,
```
 transformations

    0.15, 0.3, 0.3), sigma = 25))

fit.1 <- secr.fit(CH, trace = FALSE)
fit.tvc2 <- secr.fit(CH, model = g0 ~ blockt, trace = FALSE)

# because variation aligns with occasions, we get the same with:
fit.t2 <- secr.fit(CH, model = g0 ~ tcov, timecov = c(1,1,2,2,2),
                   trace = FALSE)
predict(fit.t2, newdata = data.frame(tcov = 1:2))
predict(fit.tvc2, newdata = data.frame(blockt = 1:2))

# now model some more messy variation
covariates (traps(CH))[1:10,] <- 3
fit.tvc3 <- secr.fit(CH, model = g0 ~ blockt, trace = FALSE)

AIC(fit.tvc2, fit.t2, fit.tvc3)
# fit.tvc3 is the 'wrong' model

## End(Not run)

transformations  Transform Point Array

Description

Flip (reflect), rotate or slide (translate) an array of points. Methods are provided for ‘traps’ objects that ensure other attributes are retained. The methods may be used with rbind.traps to create complex geometries.

Usage

flip (object, lr = FALSE, tb = FALSE, ...)
rotate (object, degrees, centrexy = NULL, ...)
shift (object, shiftxy, ...)

## S3 method for class 'traps'
flip(object, lr = FALSE, tb = FALSE, ...)
## S3 method for class 'traps'
rotate(object, degrees, centrexy = NULL, ...)
## S3 method for class 'traps'
shift(object, shiftxy, ...)

## S3 method for class 'popn'
flip(object, lr = FALSE, tb = FALSE, ...)
## S3 method for class 'popn'
transformations

rotate(object, degrees, centrexy = NULL, ...)
## S3 method for class 'popn'
shift(object, shiftxy, ...)

## S3 method for class 'mask'
shift(object, shiftxy, ...)

Arguments

object  a 2-column matrix or object that can be coerced to a matrix
lr      either logical for whether array should be flipped left-right, or numeric value for
        x-coordinate of axis about which it should be flipped left-right
tb      either logical for whether array should be flipped top-bottom, or numeric value for
        y-coordinate of axis about which it should be flipped top-bottom
degrees clockwise angle of rotation in degrees
centrexy vector with xy coordinates of rotation centre
shiftxy vector of x and y displacements
...     other arguments (not used)

Details

flip reflects points about a vertical or horizontal axis. Logical values for lr or tb indicate that
points should be flipped about the mean on the relevant axis. Numeric values indicate the particular
axis value(s) about which points should be flipped. The default arguments result in no change.
shift shifts the location of each point by the desired amount on each axis.
rotate rotates the array about a designated point. If centrexy is NULL then rotation is about
(0,0) (rotate.default), the array centre (rotate.traps), or the centre of the bounding box
(rotate.popn).

Value

A matrix or object of class ‘traps’ or ‘popn’ with the coordinates of each point transformed as
requested.

trats, popn

Examples

temp <- matrix(runif(20) * 2 - 1, nc = 2)

## flip
temp2 <- flip(temp, lr = 1)
plot(temp, xlim=c(-1.5,4), ylim = c(-1.5,1.5), pch = 16)
points (temp2, pch = 1)
trap.builder

### Description

Construct detector layouts comprising small arrays (clusters) replicated across space, possibly at a probability sample of points.

### Usage

```r
trap.builder (n = 10, cluster, region = NULL, frame = NULL, method = c("SRS", "GRTS", "all", "rank"),
```
edgemethod = c("clip", "allowoverlap", "allinside", "anyinside", "centreinside"), samplefactor = 2, ranks = NULL, rotation = NULL, detector, exclude = NULL, exclmethod = c("clip", "alloutside", "anyoutside", "centreoutside"), plt = FALSE, add = FALSE, ...)

mash (object, origin = c(0,0), clustergroup = NULL, ...)

cluster.counts (object)

cluster.centres (object)

Arguments

n integer number of clusters (ignored if method = "all")
cluster traps object
region bounding polygon(s)
frame data frame of points used as a finite sampling frame
method character string (see Details)
edgemethod character string (see Details)
samplefactor oversampling to allow for rejection of edge clusters (multiple of n)
ranks vector of relative importance (see Details)
rotation angular rotation of each cluster about centre (degrees)
detector character detector type (see detector)
exclude polygon(s) from which detectors are to be excluded
exclmethod character string (see Details)
plt logical: should array be plotted?
add logical: add to existing plot
object single-session multi-cluster capthist object, or traps object for cluster.centres
origin new coordinate origin for detector array
clustergroup list of vectors subscripting the clusters to be mashed
... other arguments passed by trap.builder to spsurvey::grts (e.g., mindis) and by mash to make.capthist (e.g., sortrows)

Details

The detector array in cluster is replicated n times and translated to centres sampled from the area sampling frame in region or the finite sampling frame in frame. Each cluster may be rotated about its centre either by a fixed number of degrees (rotation positive), or by a random angle (rotation negative).

If the cluster argument is not provided then single detectors of the given type are placed according to the design.
The sampling frame is finite (the points in frame) whenever frame is not NULL. If region and frame are both specified, sampling uses the finite frame but sites may be clipped using the polygon. Method may be "SRS", "GRTS", "all" or "rank". "SRS" takes a simple random sample (without replacement in the case of a finite sampling frame). "GRTS" takes a spatially representative sample using the 'generalized random tessellation stratified' (GRTS) method of Stevens and Olsen (2004). "all" replicates cluster across all points in the finite sampling frame. "rank" selects n sites from frame on the basis of their ranking on the vector ‘ranks’, which should have length equal to the number of rows in frame; ties are resolved by drawing a site at random.

Options for edgemethod are –

<table>
<thead>
<tr>
<th>edgemethod</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;clip&quot;</td>
<td>reject any individual detectors outside region</td>
</tr>
<tr>
<td>&quot;allowoverlap&quot;</td>
<td>no action</td>
</tr>
<tr>
<td>&quot;allinside&quot;</td>
<td>reject whole cluster if any component is outside region</td>
</tr>
<tr>
<td>&quot;anyinside&quot;</td>
<td>reject whole cluster if no component is inside region</td>
</tr>
<tr>
<td>&quot;centreinside&quot;</td>
<td>reject whole cluster if centre outside region, and clip to region</td>
</tr>
</tbody>
</table>

Similarly, exclmethod may be "clip" (reject individual detectors), "alloutside" (reject whole cluster if any component is outside exclude) etc. Sufficient additional samples ((samplefactor--1) * n) must be drawn to allow for replacement of any rejected clusters; otherwise, an error is reported (‘not enough clusters within polygon’).

GRTS samples require function grts in version >= 5.3.0 of package spsurvey (Dumelle et al. 2022). More sophisticated stratified designs may be specified by using grts directly.

mash collapses a multi-cluster capthist object as if all detections were made on a single cluster. The new detector coordinates in the ‘traps’ attribute are for a single cluster with (min(x), min(y)) given by origin. clustergroup optionally selects one or more groups of clusters to mash; if length(clustergroup) > 1 then a multisession capthist object will be generated, one ‘session’ per cluster group. By default, all clusters are mashed.

mash discards detector-level covariates and occasion-specific ‘usage’, with a warning.

cluster.centres returns the centroid of the detector locations in each cluster. When clusters have been truncated these differ from the attribute centres set by make.systematic.

Value

trap.builder produces an object of class ‘traps’.

plt = TRUE causes a plot to be displayed, including the polygon or finite sampling frame as appropriate.

mash produces a capthist object with the same number of rows as the input but different detector numbering and ‘traps’. An attribute ‘n.mash’ is a vector of the numbers recorded at each cluster; its length is the number of clusters. An attribute ‘centres’ is a dataframe containing the x-y coordinates of the cluster centres. The predict method for secr objects and the function derived both recognise and adjust for mashing.
cluster.counts returns a vector with the number of individuals detected at each cluster.
cluster.centres returns a dataframe of x- and y-coordinates.

Note
The function `make.systematic` should be used to generate systematic random layouts. It calls `trap.builder`.
The sequence number of the cluster to which each detector belongs, and its within-cluster sequence number, may be retrieved with the functions `clusterID` and `clustertrap`.

traps

**Detector Array**

### Description

An object of class `traps` encapsulates a set of detector (trap) locations and related data. A method of the same name extracts or replaces the `traps` attribute of a `capthist` object.

### Usage

```
traps(object, ...)  
traps(object) <- value  
```

### Arguments

- `object`  
a `capthist` object.
- `value`  
traps object to replace previous.
- `...`  
other arguments (not used).

### Details

An object of class `traps` holds detector (trap) locations as a data frame of x-y coordinates. Trap identifiers are used as row names. The required attribute 'detector' records the type of detector ("single", "multi" or "proximity" etc.; see `detector` for more).

Other possible attributes of a `traps` object are:

- `spacing`  
mean distance to nearest detector
- `spacex`  

- `spacex`  

- `spacy`  

- `covariates`  
dataframe of trap-specific covariates
- `clusterID`  
identifier of the cluster to which each detector belongs
- `clustertrap`  
sequence number of each trap within its cluster
- `usage`  
a traps x occasions matrix of effort (may be binary 0/1)
- `markocc`  
integer vector distinguishing marking occasions (1) from sighting occasions (0)
- `newtrap`  
vector recording aggregation of detectors by `reduce.traps`
If usage is specified, at least one detector must be ‘used’ (usage non-zero) on each occasion.

Various array geometries may be constructed with functions such as `make.grid` and `make.circle`, and these may be combined or placed randomly with `trap.builder`.

**Note**

Generic methods are provided to select rows (`subset.traps`), combine two or more arrays (`rbind.traps`), aggregate detectors (`reduce.traps`), shift an array (`shift.traps`), or rotate an array (`rotate.traps`).

The attributes `usage` and `covariates` may be extracted or replaced using generic methods of the same name.

**References**

**See Also**

`make.grid`, `read.traps`, `rbind.traps`, `reduce.traps`, `plot.traps`, `secr.fit`, `spacing`, `detector`, `covariates`, `trap.builder`, `as.mask`

**Examples**

```r
demotraps <- make.grid(nx = 8, ny = 6, spacing = 30)
demotraps  ## uses print method for traps
summary (demotraps)

plot (demotraps, border = 50, label = TRUE, offset = 8,
gridlines=FALSE)

## generate an arbitrary covariate `randcov`
covariates (demotraps) <- data.frame(randcov = rnorm(48))

## overplot detectors that have high covariate values
#temptr <- subset(demotraps, covariates(demotraps)$randcov > 0.5)
#plot (temptr, add = TRUE,
#detpar = list (pch = 16, col = "green", cex = 2))```

```
Detector Attributes

Description

Extract or replace attributes of an object of class ‘traps’.

Usage

polyID(object)
polyID(object) <- value
transectID(object)
transectID(object) <- value
searcharea(object)
transectlength(object)

Arguments

object a ‘traps’ object
value replacement value (see Details)

Details

The ‘polyID’ and ‘transectID’ functions assign and extract the attribute of a ‘traps’ object that relates vertices (rows) to particular polygons or transects. The replacement value should be a factor of length equal to nrow(object).

The ‘searcharea’ of a ‘polygon’ traps object is a vector of the areas of the component polygons in hectares. This value is read-only.

The ‘transectlength’ of a ‘transect’ traps object is a vector of the lengths of the component transects in metres. This value is read-only.

Value

polyID - a factor with one level per polygon. searcharea - numeric value of polygon areas, in hectares. transectlength - numeric value of transect lengths, in metres.

See Also

traps

Examples

## default is a single polygon
temp <- make.grid(detector = "polygon", hollow = TRUE)
polyID(temp)
plot(temp)
Trend

Function for multi-session density trend analysis.

Usage

predictDlambda(object, alpha = 0.05)

Arguments

- `object`: multi-session secr object output from secr.fit
- `alpha`: alpha level for confidence intervals

Details

Usage is described in secr-trend.pdf. Briefly, setting details argument 'Dlambda' in `secr.fit` causes the density model (D~xxx) to be interpreted as a session-specific trend model with parameters for the initial density (D1) and each subsequent session-on-session change in density $\lambda[t] = D[t + 1]/D[t]$.

Value

A table of session-specific estimates (initial D, subsequent $\lambda[t]$) with SE and confidence intervals.

See Also

predictDsurface, secr.fit

Examples

```
# a model with constant lambda
msk <- make.mask(traps(ovenCH[[1]]), buffer = 300, nx = 25)
fit <- secr.fit(ovenCH, model = D~1, mask = msk, trace = FALSE,
                details = list(Dlambda = TRUE), ncores = 2)
predictDlambda(fit)
```
Description

Drop unwanted components from a list object, usually to save space.

Usage

```r
## Default S3 method:
trim(object, drop, keep)
## S3 method for class 'secr'
trim(object, drop = c("call", "mask", "designD", "designNE",
                    "design", "design0"), keep = NULL)
## S3 method for class 'secrlist'
trim(object, drop = c("call", "mask", "designD", "designNE",
                    "design", "design0"), keep = NULL)
```

Arguments

- `object` - a list object
- `drop` - vector identifying components to be dropped
- `keep` - vector identifying components to be kept

Details

- `drop` may be a character vector of names or a numeric vector of indices. If both `drop` and `keep` are given then the action is conservative, dropping only components in `drop` and not in `keep`.
- Be warned that some further operations on fitted secr objects become impossible once you have discarded the default components.

Value

- a list retaining selected components.
Troubleshooting

Examples

names(secrdemo.0)
names(trim(secrdemo.0))

object.size(secrdemo.0)
object.size(trim(secrdemo.0))

object.size(trim(secrlist(secrdemo.0, secrdemo.b)))

Troubleshooting Problems in Fitting SECR Models

Description

Although secr.fit is quite robust, it does not always work. Inadequate data or an overambitious model occasionally cause numerical problems in the algorithms used for fitting the model, or problems of identifiability, as described for capture–recapture models in general by Gimenez et al. (2004). Here are some tips that may help you.

This page has largely been superseded by secr-troubleshooting.pdf.

The log-likelihood values shown with trace = TRUE are all NA

Most likely you have infeasible starting values for the parameters. try some alternatives, specifying them manually with the start argument.

secr.fit finishes, but some or all of the variances are missing

This usually means the model did not fit and the estimates should not be trusted. Extremely large variances or standard errors also indicate problems.

• Try another maximization method (method = "Nelder-Mead" is more robust than the default). The same maximum likelihood should be found regardless of method, so AIC values are comparable across methods.

• Repeat the maximization with different starting values. You can use secr.fit(..., start = last.model) where last.model is a previously fitted secr object.

• If you think the estimates are right but there was a problem in computing the variances, try re-running secr.fit() with the previous model as starting values (see preceding) and set method = "none". This bypasses maximization and computes the variances afresh using fdHess from nlme.

• Try a finer mask (e.g., vary argument nx in make.mask). Check that the extent of the mask matches your data.
Troubleshooting

• The maximization algorithms work poorly when the beta coefficients are of wildly different magnitude. This may happen when using covariates: ensure beta coefficients are similar (within a factor of 5–10 seems adequate, but this is not based on hard evidence) by scaling any covariates you provide. This can be achieved by setting the typsize argument of nlm or the parscale control argument of optim.

• Examine the model. Boundary values (e.g., g0 near 1.0) may give problems. In the case of more complicated models you may gain insight by fixing the value of a difficult-to-estimate parameter (argument fixed).

See also the section ‘Potential problems’ in secr-densitysurfaces.pdf.

secr.fit finishes with warning nlm code 3

This condition does not invariably indicate a failure of model fitting. Proceed with caution, checking as suggested in the preceding section.

secr.fit crashes part of the way through maximization

A feature of the maximization algorithm used by default in nlm is that it takes a large step in the parameter space early on in the maximization. The step may be so large that it causes floating point underflow or overflow in one or more real parameters. This can be controlled by passing the ‘stepmax’ argument of nlm in the . . . argument of secr.fit (see first example). See also the previous point about scaling of covariates.

secr.fit demands more memory than is available

This is a problem particularly when using individual covariates in a model fitted by maximizing the conditional likelihood. The memory required is then roughly proportional to the product of the number of individuals, the number of occasions, the number of detectors and the number of latent classes (for finite-mixture models). When maximizing the full-likelihood, substitute ‘number of groups’ for ‘number of individuals’. [The limit is reached in external C used for the likelihood calculation, which uses the R function ‘R_alloc’.]

The mash function may be used to reduce the number of detectors when the design uses many identical and independent clusters. Otherwise, apply your ingenuity to simplify your model, e.g., by casting ‘groups’ as ‘sessions’. Memory is less often an issue on 64-bit systems (see link below).

Estimates from mixture models appear unstable

These models have known problems due to multimodality of the likelihood. See secr-finitemixtures.pdf.

secr.fit, Memory-limits
Description

\texttt{sim.popn} can simulate a multi-session population with known between-session survival, recruitment and movement probabilities. The parameter settings to achieve this are passed to \texttt{sim.popn} in its 'details' argument. Components of 'details' that are relevant to turnover are described below; see \texttt{sim.popn} for others.

Multi-session populations are generated in \texttt{sim.popn} whenever its argument 'nsessions' is greater than 1. If \texttt{details$lambda} remains NULL (the default) then the population for each successive session is generated de novo from the given density model (model2D, D etc.). If a value is specified for \texttt{details$lambda} then only the first population is generated de novo; remaining populations are generated iteratively with probabilistic mortality, recruitment and movement as described here.

**Turnover components of \texttt{sim.popn details argument}**

</tr>
</tbody>
</table>

Survival

Survival is usually thought of as a Bernoulli process (outcome 0 or 1 for each individual) so the number of survivors $S$ is a binomial variable (survmodel = "binomial"). Another approach is to fix the proportion surviving, but this can be done exactly only when $\phi N$ is an integer. A (slightly ad hoc) solution is to randomly choose between the two nearest integers with probability designed in the long term (over many sessions) to give the required $\phi$ (survmodel = "discrete").

Population growth and recruitment

Per capita recruitment ($f$) is the difference between lambda and phi ($f = \lambda - \phi$), which must be non-negative (phi > lambda causes an error). The number of recruits $B$ is a random variable whose
probability distribution is controlled by details$recrmodel:

<table>
<thead>
<tr>
<th>Value</th>
<th>Probability model</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;constantN&quot;</td>
<td>Exact replacement of animals that die ($B = N_t - S$)</td>
</tr>
<tr>
<td>&quot;binomial&quot;</td>
<td>Binomial number of recruits ($B \sim \text{bin}(N_t, f)$)</td>
</tr>
<tr>
<td>&quot;poisson&quot;</td>
<td>Poisson number of recruits ($B \sim \text{pois}(f N_t)$)</td>
</tr>
<tr>
<td>&quot;discrete&quot;</td>
<td>Minimum-variance number of recruits (see Survival)</td>
</tr>
<tr>
<td>&quot;multinomial&quot;</td>
<td>The POPAN model, conditioning on superpopulation size (e.g., Schwarz and Arnason 1996)</td>
</tr>
<tr>
<td>&quot;specified&quot;</td>
<td>Add the number of recruits specified in Nrecruits (may be vector)</td>
</tr>
</tbody>
</table>

In the case of binomial recruitment there is a maximum of one recruit per existing individual, so $\lambda \leq (\phi + 1)$. Multinomial recruitment requires a value for the superpopulation size. This may be provided as the details component "superN". If not specified directly, a value is inferred by projecting a trial initial (simulated) population using the specified phi and lambda.

Specifying the integer number of recruits in each year (recrmodel 'specified') overrides the value of lambda, but a non-null value should be given for lambda.

**Movement**

Individuals may shift their home range centre between sessions. Movement probability is governed by a circular kernel specified by 'movemodel' and the parameter values 'move.a' and 'move.b' (optional). By default there is no movement between sessions (movemodel = "static"). Other options are

- "IND" "uncorrelated" individuals are randomly assigned a new, independent location within the buffered area
- "BVN" "normal" bivariate normal (Gaussian) kernel with parameter move.a (previously called sigma.m)
- "BVE" "exponential" negative exponential (Laplace) kernel with parameter move.a
- "BVT" "t2D" circular 2-dimensional t-distribution with scale parameter move.a and shape parameter move.b = df/2
- "RDE" exponential distribution of radial distance (Ergon & Gardner, 2014)
- "RDG" gamma distribution of radial distance (Ergon & Gardner, 2014)
- "RDL" log-normal distribution of radial distance (Ergon & Gardner, 2014)

The parameterized with move.a = exp(mu), move.b = 1/CV^2 = 1 / (exp(SD^2) - 1)

The package openCR >=1.4.0 provides functions for constructing and plotting these kernels and summarising their properties (make.kernel; plot and summary methods for kernel objects). The secr function extractMoves is useful for checking simulations of movement.

Models IND, BVN, BVE, and RDE may also be zero-inflated (suffix "zi"). The parameter ‘move.a’ (INDzi) or ‘move.b’ (BVNzi, BVEzi, RDEzi) is the zero-inflation probability. See Examples.

In secr <3.2.1 sigma.m was also used to indicate two special cases; these continue to work but may be discontinued in the future:

- sigma.m = 0 corresponds to movemodel = ‘static’
- sigma.m < 0 corresponds to movemodel = ‘uncorrelated’

In secr >= 4.4.0, the ‘movemodel’ component may also be a user-provided function with these characteristics: two or three arguments, the first being the number of centres to be moved (e.g., n)
and the others parameters of the dispersal distribution (e.g., a,b); the function should return a matrix of n rows and 2 columns, the displacements in the x- and y-directions. The output is a set of random points from the bivariate dispersal kernel. The function will be called with the current number of centres and parameter values move.a and move.b as needed.

If movement takes an animal across the boundary of the arena (buffered area) in sim.popn the component "edgemethod" comes into play. By default, locations are toroidally wrapped i.e. the animal re-joins the population on the opposing edge. Other options are “clip” (discard), “clipandreplace” (assign new identity at original location), “stop” (stop just inside the boundary), “reflect” (bounce off edges to the limit of the dispersal), “normalize” = “truncate” (truncate kernel and scale probability to 1.0) and “none” (allow centres outside the buffered area). The “normalize” option (new in secr 4.3.3) can take longer as it repeatedly relocates each individual until its destination lies within the bounding box, up to a maximum of 500 attempts.

---

### Description

Before version 3.0, the internal data format for data from exclusive detectors (single, multi, proximityX, transectX) was a matrix with one row per detected animal and one column per sampling occasion; each cell was either zero or the number of the detector at which the animal was detected (with switched sign if the animal died). The format for data from proximity and other detectors was a 3-dimensional array (third dimension corresponding to detectors) that allowed more than one detection per animal per occasion.

From secr 3.0 all capthist data use the 3-D format internally. This simplifies a lot of the coding, and enables mixing of detector types within a session. The constraint that only one detection is allowed per animal per occasion at exclusive detectors is imposed by verify().

The data input functions (read.capthist etc.) automatically generate objects in the new format. Objects created and saved under earlier versions should be converted if they relate to the ‘exclusive’ detector types listed above.

### Usage

updateCH(object)

### Arguments

- **object**: capthist object

### Details

The function reduce.capthist is applied with the nominal detector type as the outputdetector.

### Value

Object with same class as the input.

Updating has the side effect of discarding invalid supernumerary detections (e.g. if there were two detections of an animal on one occasion, only one will be included).
Examples

```r
# if we had the old ovenCH
sapply(ovenCH, dim)
sapply(updateCH(ovenCH), dim)
```

## Description

Extract or replace usage (effort) information of a `traps` object (optional).

### Usage

```r
usage(object, ...)  
usage(object) <- value
```

### Arguments

- `object`: `traps` object
- `value`: numeric matrix of detectors x occasions
- `...`: other arguments (not used)

### Details

In secr versions before 2.5.0, usage was defined as a binary value (1 if trap \( k \) used on occasion \( s \), zero otherwise).

In later versions, usage may take nonnegative real values and will be interpreted as effort. This corresponds to the constant \( T_s \) used for the duration of sampling by Borchers and Efford (2008). Effort is modelled as a known linear coefficient of detection probability on the hazard scale (secre-\textunderscore varyingeffort.pdf; Efford et al. 2013).

For replacement of usage, various forms are possible for `value`:

- a matrix in which the number of rows of `value` exactly matches the number of traps \( K \) in `object`  
- a vector of two values, the usage (typically 1) and the number of occasions \( S \) (a \( K \times S \) matrix will be filled with the first value)  
- a vector of \( R+1 \) values where \( R \) is the number of sessions in a multi-session object and elements 2..\( R+1 \) correspond to the numbers of occasions \( S_1, S_2, \ldots \) in each session  
- the usage only (typically 1) (only works when replacing an existing usage matrix with known number of occasions).

### Value

`usage(object)` returns the usage matrix of the `traps` object. `usage(object)` may be NULL.
Note

At present, assignment of usage to the traps objects of a multisession capthist object results in the loss of session names from the latter.

## restore lost names
names(ovenCH) <- 2005:2009

usagePlot

Plot usage, detections or sightings.

Description

usagePlot displays variation in effort (usage) over detectors as a bubble plot (circles with radius scaled so that area is proportional to effort).

sightingPlot displays spatial variation in the number of sightings at each detector as a bubble plot (circles with radius scaled so that area is proportional to either the average number per occasion or the total over occasions.

Usage

usagePlot(object, add = FALSE, occasions = NULL, col = "black", fill = FALSE, scale = 2, metres = TRUE, rad = 5, ...)
sightingPlot(object, type = c("Detections", "Tu", "Tm", "Tn"), add = FALSE, occasions = "ALL", mean = TRUE, col = "black", fill = FALSE, scale = 2, metres = TRUE, dropunused = TRUE, title = type, legend = c(1, 2, 4, 8), px = 0.95, py = 0.95, ...)
usagePlot

Arguments

- **object**: traps object with usage attribute
- **add**: logical; if FALSE plot.traps is called to create a base plot
- **occasions**: integer number(s) of the occasion(s) for which effort is plotted, "ALL", or NULL
- **col**: character or integer colour value
- **fill**: logical; if TRUE the circle is filled with the line colour
- **scale**: numeric value used to scale radius
- **metres**: logical; if TRUE scale is a value in metres (see Details)
- **rad**: numeric; radial displacement of symbol centre for each occasion from true detector location (metres)
- **...**: other arguments passed to plot.traps
- **type**: character to choose among sighting types and detections of marked animals
- **mean**: logical; if TRUE then the plotted value is the average over occasions, otherwise the sum
- **dropunused**: logical; if TRUE then detectors are omitted when they were unused on occasions
- **title**: character
- **legend**: numeric values for which legend circles will be drawn
- **px**: legend x position as fraction of user coordinates
- **py**: legend y position as fraction of user coordinates

Details

The behaviour of usagePlot is described first. By default (occasion = NULL) circles representing usage on each occasion are plotted around the detector location at distance rad, as in the petal plot of plot.capthist. Otherwise, the usage on a single specified occasion, or summed over occasions (length(occasion)>1, or occasion = "ALL"), is plotted as a circle centred at the detector location.

Package sp provides an alternative to usagePlot (see Examples).

sightingPlot may be used to display either detections of marked animals (whether or not occasions refers to sighting occasions) or any of the sighting attributes (unmarked sightings ‘Tu’, marked, unidentified sightings ‘Tm’, or other uncertain sightings ‘Tn’).

If py is of length 2 then the values determine the vertical spread of symbols in the legend.

For both functions –

The metres argument switches between two methods. If metres = TRUE, the symbols function is used with inches = FALSE to plot circles with radius scaled in the units of object (i.e. metres; scale is then the radius in metres of the symbol for a detector with usage = 1.0). Otherwise, plotting uses points; this has the advantage of producing better filled circles, but a suitable value of scale must be found by trial and error.

Value

No value is returned by usagePlot.

sightingPlot invisibly returns a ‘traps’ object with a covariate ‘f’ holding the plotted values.
userdist

Non-Euclidean Distances

Description

Non-Euclidean distances have a variety of uses, some obscure. You probably do not need them unless you have data from linear habitats, covered in the forthcoming package secrlinear. On the other hand, they open up some intriguing possibilities for the advanced user. The key is to provide an appropriate value for the component ‘userdist’ of the details argument of secr.fit.

details$userdist is either a function to compute distances between detectors and mask points, or a pre-computed matrix of such distances. Pre-computing assumes the matrix is static (i.e. fixed and not dependent on any estimated coefficients). The functions edist and nedist are useful for computing static matrices of Euclidean or non-Euclidean distances (the latter is useful when there are barriers to movement).

If details$userdist is a function then it should take the form

userdist(xy1, xy2, mask)
Arguments

- **xy1**: 2-column matrix of x-y coordinates of *k* detectors
- **xy2**: 2-column matrix of x-y coordinates of *m* mask points
- **mask**: habitat mask defining a non-Euclidean habitat geometry

Details

The matrix returned by the function must have exactly *k* rows and *m* columns. The function name may be almost anything you like.

The non-Euclidean habitat geometry may or may not require access to local density (D), local (mask) covariates, and the estimation of additional coefficients (beta variables). In order that secr.fit can assemble these data, there is a mechanism for the user to indicate which, if any, variables are required: when called with no arguments the function should return a character vector of variable names. These may include covariates of ‘mask’, the dynamically computed density ‘D’, and a special real parameter ‘noneuc’ for which one or more coefficients will be fitted.

‘noneuc’ is like ‘D’ in that it may be modelled as a function of any mask covariates, session, Session, x, y, etc. The actual meaning attributed to ‘noneuc’ depends entirely on how it is used inside the function.

The function may require no variables and not require estimation of additional coefficients. This is the case for a simple linear geometry as described in documentation for the package ‘secrlinear’.

<table>
<thead>
<tr>
<th>Value</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>no covariates etc. required</td>
</tr>
<tr>
<td>’D’</td>
<td>density at each mask point</td>
</tr>
<tr>
<td>’noneuc’</td>
<td>a multi-purpose real parameter</td>
</tr>
<tr>
<td></td>
<td>defined for each mask point</td>
</tr>
<tr>
<td>c(’D’, ’noneuc’)</td>
<td>both of the preceding</td>
</tr>
<tr>
<td>c(’noneuc’,’habclass’)</td>
<td>both noneuc and the mask covariate ’habclass’</td>
</tr>
</tbody>
</table>

The last case does not estimate a coefficient for habclass, it merely makes the raw value available to whatever algorithm you implement.

The ‘xy2’ and ‘mask’ parameters of the userdist function overlap in practice: xy1 and xy2 only define the points between which distances are required, whereas mask is a carrier for any and all additional information needed by the algorithm.

Full documentation of the *secr* capability for non-Euclidean distances is in the separate document *secr-noneuclidean.pdf*, which includes example code for the analysis of Sutherland et al. (2015).

Compatibility

User-specified distances are compatible with some but not all features of *secr*. Functions with a ‘userdist’ argument are certainly compatible, and others may be.

With a static userdist, region.N will generally not calculate population size for a region other than the original mask. If you want to supply a new mask in the ‘region’ argument, replace x$details$userdist with a distance matrix appropriate to the new mask, where ‘x’ is the name of the fitted model.
User-specified distances cannot be used with polygon or transect detectors.

When using `sim.capthist` to simulate detections of a new population from `sim.popn` you must provide `userdist` as a function rather than a matrix. This is because new animals are not restricted to locations on the ‘mask’ grid.

References

See Also

details, secr.fit, nedist

Examples

```r
## see secr-noneuclidean.pdf
```
Details

getmeanSD is used by make.mask to standardize mask coordinates.

For masklength the input should be a linear mask from secrlinear.

edist computes the Euclidean distance between each point in xy1 and each point in xy2. (This duplicates the functionality of ‘rdist’ in package fields).

nedist computes the non-Euclidean distance between each point in xy1 and each point in xy2, in two dimensions. The calculation uses gdistance (van Etten 2017; see also Csardi & Nepusz 2006): a transition layer is formed representing the connections between adjacent points in mask. By default, points within a 16-point neighbourhood are considered ‘adjacent’. Distances are obtained by Dijkstra’s (1959) algorithm as least cost paths through the graph of all points in the mask.

nedist has some subtle options. If ‘mask’ is missing then the transition layer will be formed from ‘xy2’. If ‘mask’ has a covariate named ‘noneuc’ then this will be used to weight distances. The ...argument of neddists allows the user to vary arguments of transition (defaults transitionFunction = mean and directions = 16). Be warned this can lead to unexpected results! Point pairs that are completely separated receive the distance +Inf unless a finite value is provided for the argument ‘inf’. See secr-noneuclidean.pdf for uses of nedist.

Value

For getMeanSD, a dataframe with columns ‘x’ and ‘y’ and two rows, mean and SD.

For maskarea, the summed area of mask cells in hectares (ha).

For masklength, the summed length of mask cells in kilometers (km).

For edist and nedist, a matrix with dim = c(nrow(xy1), nrow(xy2)).

References

Examples

getMeanSD(possummask)
Description

Variance-covariance matrix of beta or real parameters from fitted secr model.

Usage

## S3 method for class 'secr'
vcov(object, realnames = NULL, newdata = NULL,
      byrow = FALSE, ...)

Arguments

- **object**: secr object output from the function `secr.fit`
- **realnames**: vector of character strings for names of ‘real’ parameters
- **newdata**: dataframe of predictor values
- **byrow**: logical for whether to compute covariances among ‘real’ parameters for each row of new data, or among rows for each real parameter
- **...**: other arguments (not used)

Details

By default, returns the matrix of variances and covariances among the estimated model coefficients (beta parameters).

If `realnames` and `newdata` are specified, the result is either a matrix of variances and covariances for each ‘real’ parameter among the points in predictor-space given by the rows of `newdata` or among real parameters for each row of `newdata`. Failure to specify `newdata` results in a list of variances only.

Value

A matrix containing the variances and covariances among beta parameters on the respective link scales, or a list of among-parameter variance-covariance matrices, one for each row of `newdata`, or a list of among-row variance-covariance matrices, one for each ‘real’ parameter.

vcov, secr.fit, print.secr

Examples

## previously fitted secr model
vcov(secrdemo.0)
**verify**

*Check SECR Data*

**Description**

Check that the data and attributes of an object are internally consistent to avoid crashing functions such as secr.fit

**Usage**

```r
## Default S3 method:
verify(object, report, ...)  
## S3 method for class 'traps'
verify(object, report = 2, ...)  
## S3 method for class 'capthist'
verify(object, report = 2, tol = 0.01, ...)  
## S3 method for class 'mask'
verify(object, report = 2, ...)
```

**Arguments**

- **object**: an object of class ‘traps’, ‘capthist’ or ‘mask’
- **report**: integer code for level of reporting to the console. 0 = no report, 1 = errors only, 2 = full.
- **tol**: numeric tolerance for deviations from transect line (m)
- **...**: other arguments (not used)

**Details**

Checks are performed specific to the class of ‘object’. The default method is called when no specific method is available (i.e. class not ‘traps’, ‘capthist’ or ‘mask’), and does not perform any checks.

**verify.capthist**

1. No ‘traps’ component
2. Invalid ‘traps’ component reported by verify.traps
3. No live detections
4. Missing values not allowed in capthist
5. Live detection(s) after reported dead
6. Empty detection histories (except concurrent telemetry and all-sighting data)
7. More than one capture in single-catch trap(s)
8. More than one detection per detector per occasion at proximity detector(s)
9. Signal detector signal(s) less than threshold or invalid threshold
10. Number of rows in ‘traps’ object not compatible with reported detections
11. Number of rows in dataframe of individual covariates differs from capthist
12. Number of occasions in usage matrix differs from capthist
13. Detections at unused detectors
14. Number of coordinates does not match number of detections (‘polygon’, ‘polygonX’, ‘transect’ or ‘transectX’ detectors)
15. Coordinates of detection(s) outside polygons (‘polygon’ or ‘polygonX’ detectors)
16. Coordinates of detection(s) do not lie on any transect (‘transect’ or ‘transectX’ detectors)
17. Row names (animal identifiers) not unique
18. Levels of factor covariate(s) differ between sessions

verify.traps

1. Missing detector coordinates not allowed
2. Number of rows in dataframe of detector covariates differs from expected
3. Number of detectors in usage matrix differs from expected
4. Occasions with no used detectors
5. Polygons overlap
6. Polygons concave east-west (‘polygon’ detectors)
7. PolyID missing or not factor
8. Polygon detector is concave in east-west direction
9. Levels of factor trap covariate(s) differ between sessions

verify.mask

1. Valid x and y coordinates
2. Number of rows in covariates dataframe differs from expected
3. Levels of factor mask covariate(s) differ between sessions

Earlier errors may mask later errors: fix & re-run.

Value

A list with the component errors, a logical value indicating whether any errors were found. If object contains multi-session data then session-specific results are contained in a further list component bysession.

Full reporting is the same as ‘errors only’ except that a message is posted when no errors are found.

Examples

```r
verify(captdata)

## create null (complete) usage matrix, and mess it up
temptraps <- make.grid()
usage(temptraps) <- matrix(1, nr = nrow(temptraps), nc = 5)
usage(temptraps)[,5] <- 0
verify(temptraps)

## create mask, and mess it up
tempmask <- make.mask(temptraps)
verify(tempmask)
tempmask[1,1] <- NA
verify(tempmask)
```
writeGPS

Usage

writeGPS(xy, o = "garmin", F = "usb:\", proj = "+proj=nzmg")
writeGPS

Arguments

xy 2-column matrix or dataframe of x-y coordinates

o character output format (see GPSBabel documentation)

F character for destination (see Details)

proj character string describing projection

Details

This function is derived in part from readGPS in maptools.

For users of Garmin GPS units, useful values of o are "garmin" for direct upload via USB or serial ports, and "gdb" for a file in Mapsource database format.

F may be "usb:" or "com4:" etc. for upload via USB or serial ports, or the name of a file to create.

The proj argument may be complex. For further information see the Examples and the vignette secr-spatialdata.pdf. If proj is an empty string then coordinates are assumed already to be latitudes (column 1) and longitudes (column 2).

Waypoint names are derived from the rownames of xy.

Value

No value is returned. The effect is to upload waypoints to an attached GPS or file.

Note

GPSBabel is available free from https://www.gpsbabel.org/. Remember to add it to the Path. On Windows this means following something like Settings > Control panel > System > Advanced settings > Environment variables > (select Path) Edit and adding ";C:/Program Files (x86)/gpsbabel" to the end (without the quotes). Or ";C:/Program Files/gpsbabel" on 32-bit systems.

Examples

## Example using shapefile "possumarea.shp" in
## "extdata" folder. As 'cluster' is not specified,
## the grid comprises single multi-catch detectors.

## Not run:

## test for availability of GPSBabel

if (nzchar(Sys.which("gpsbabel"))) {

library(sf)
shpfilename <- system.file("extdata/possumarea.shp", package = "secr")
possumarea <- st_read(shpfilename)
possumgrid <- make.systematic(spacing = 100, region = possumarea, plt = TRUE)

## May upload directly to GPS...
# writeGPS(possumgrid, proj = "+proj=nzmg")

## ...or save as Mapsource file
writeGPS(possumgrid, o = "gdb", F = "tempgrid.gdb",
proj = "+proj=nzmg")

## If `region` had been specified in another projection we
## would need to specify this as in Proj.4. Here is a
## hypothetical example for New Zealand Transverse Mercator
## with datum NZGD2000 (EPSG:2193)
NZTM <- paste("+proj=tmerc +lat_0=0 +lon_0=173 +k=0.9996",
   "+x_0=1600000 +y_0=10000000 +ellps=GRS80",
   " +towgs84=0,0,0,0,0,0,0 +units=m +no defs")

# writeGPS(possumgridNZTM, o = "gdb", F = "tempNZTM.txt",
# proj = NZTM)

## Or to upload coordinates from UTM Zone 18 in eastern
## Maryland, USA...
# writeGPS(MarylandUTMgrid, proj =
#   "+proj=utm +zone=18 +ellps=WGS84")

}
