Package ‘soilassessment’

August 30, 2020

Type Package

Title Assessment Models for Agriculture Soil Conditions and Crop Suitability

Version 0.2.1

Depends R (>= 3.5.0)

Imports arm, caret, Cubist, deSolve, e1071, FuzzyAHP, Hmisc, kernlab, maptools, methods, nnet, quantregForest, qrnn, randomForest, ranger, raster, rgdal, rpart, soiltexture, sp, stats, utils

Author Christian Thine Omuto

Maintainer Christian Thine Omuto <thineomuto@yahoo.com>

Description Soil assessment builds information for improved decision in soil management. It analyzes soil conditions with regard to agriculture crop suitability requirements [such as those given by FAO <http://www.fao.org/land-water/databases-and-software/crop-information/en/>] soil fertility classes, soil erosion models and soil salinity classification. Suitability requirements are for crops grouped into cereal crops, nuts, legumes, fruits, vegetables, industrial crops, and root crops.

appendTextureclass

Description
This function attaches soil textural classes according to the different soil texture classification systems.

Usage
appendTextureclass(df, method)

Arguments
- df: spatial pixel dataframe with columns of soil textural proportions clay, silt, and sand in percentages
- method: soil texture classification method for calculating soil texture. Default=USDA method

Details
df is an output of createTexturedata with spatial reference or similar dataframe with normalized proportions summing to 100. method is the texture classification method for textural class calculation. Example methods are USDA, FAO, Australian, German, etc.

Value
Output is a soil texture dataframe with textural classes for every row (or pixel) in the dataframe. The output may sometimes return double class such as "SaLo, Lo" implying possibility of a tie for two classes. Such outputs should be edited outside the package for meaningful representation of soil textural classes when necessary.

Note
This function can sometimes return double classes such as "SaLo, Lo" implying possibility of a tie for two classes.

carbonateSuit  A function for assessing calcium carbonate suitability requirements for certain crops

Description

This function determines the suitability classes for soil calcium carbonate requirements of selected agricultural crops

Usage

carbonateSuit(value, crop)

Arguments

value  Input calcium carbonate content in percent
crop   The crop of interest for which calcium carbonate suitability class is sought

Details

The input value can be map or just a numerical entry of calcium carbonate in percent

Value

The output is calcium carbonate suitability class for the crop. The output is an integer value for suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

spplot(newmap,"saffron")

Description
This function provides alternatives for implementing RothC carbon turnover model

Usage
carbonTurnover(tt,clay,C0,In,Dr=1.44,effcts,solver)

Arguments

- **tt**: a vector of time in months or years for modelling carbon turnover in the soil
- **clay**: Proportion of soil clay content in percent
- **C0**: a vector containing five initial carbon pools in the five compartments C1 in DPM, C2 in RPM, C3 in BIO, C4 in HUM and C5 in IOM. They are arranged in the order C1,C2,C3,C4,C5 \[C0=c(C1,C2,C3,C4,C5)\].
- **In**: Input carbon amount. It can be a scalar constant or a 2-column dataframe containing time dependent organic matter input. The two columns are time and carbon input
- **Dr**: ratio of decomposable plant material (DPM) to resistant plant material (RPM). Default value is 1.44
- **effcts**: a constant or dataframe of environmental effects on carbon decomposition rates. If it’s a dataframe of time-dependent variables, then the length of the dataframe should be similar to the length of time (t) vector
solver

name of subroutines for solving first order ordinary differential equations for organic matter decay in the soil. The subroutines are lsoda, lsodes, rk4, euler, lsode, lsodar, ode23, radau, etc. from deSolve

Details

vector t can be years or months sequentially arranged with the start-time as the minimum and end-time as the maximum time. Initial carbon pools are also provided as a vector of five items: C1, C2, C3, C4, C5 in that order where C1 is the pool in the decomposable plant material (DPM) compartment, C2 is pool in the resistant plant material (RPM) compartment, C3 is the pool in the microbial biomass (BIO) compartment, C4 is the pool in the humified organic matter (HUM) compartment, and C5 is the pool in the inert organic matter (IOM) compartment.

Value

n x 6 matrix of carbon pools with time in the five compartments DPM, RPM, BIO, HUM, and IOM in that order (time, C1, C2, C3, C4, C5).

CECSuit

A function for assessing Cation Exchange Capacity (CEC) suitability requirements for certain crops

Description

This function determines the suitability classes for Cation Exchange Capacity (CEC) requirements of selected agricultural crops

Usage

CECSuit(value, crop)

Arguments

value  Input cation Exchange Capacity (Cmol(+)/kg).
crop  The crop of interest for which CEC suitability class is sought

Details

The input value can be a map or just a numerical entry of CEC (cmol(+)/kg)

Value

The output is CEC suitability class for the crop. The output is an integer value for suitability class:
1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

Note

The output raster map of CEC suitability is given if the input value is raster map

classCode

A function for displaying names of class codes of soil conditions in the soilassessment package

Description

This function displays names of integer classes (or levels) of derived codes of soil conditions produced in the package

Usage

classCode(value, indicator)

Arguments

value Integer value of the soil condition indicator
indicator Soil condition whose class (x) is sought. The default = "fertility" if fertility is the soil condition

Details

This is for interpretation of the integer codes of the soil conditions generated in the package

Value

Name of the level of soil condition

See Also

classLUT, erodFUN, classnames

Examples

classCode(2,"texture")
suitclas=classCode(4,"suitability")
levels(suitclas)
A function for developing Look-up Table (LUT) for the soil condition class map

Description

This function develops a Look-Up Table (LUT) for the class type map of soil condition. LUT is important map legends or maps re-classification.

Usage

classLUT(fgrid, indicator)

Arguments

fgrid : Input classified map
indicator : The soil condition indicator of interest as contained in the input map for example, "texture", "salinity", etc.

Details

The input raster map should contain only one band for the soil indicator for clear identification of the band.

Value

The output is a dataframe containing classes in the map and corresponding unique integers

Author(s)

Christian Thine Omuto

See Also

classCode,classnames

Examples

textrd=suitabinput["texture"]

LUT=classLUT(textrd,"texture")

LUT
classnames

A function to display the class names and codes as used in the soilassessment package

Description

This is a database function for displaying the class names and codes used in the soil assessment package

Usage

classnames(indicator)

Arguments

indicator indicator of soil condition group of interest. Example: texture, suitability, drainage, fertility, erodibility

Value

Table of soil condition code and name

See Also

classCode, classLUT

Examples

x="texture"
classnames(x)

comparisonTable

A function for normalizing decision ranking table

Description

This function normalizes the decision ranking table and determines consistency of the decisions

Usage

comparisonTable(df)

Arguments

df A matrix of rank decisions with complete column names.
**createTexturedata**

Details
The column names of the rank-decision table should correspond with the names of the criteria maps

Value

- nmtx: a normalized pairwise comparison matrix
crt: consistency index and message on whether the input decisions are consistent for analysis

---

createTexturedata  A function for creating spatial dataframe of normalized soil texture proportions

Description
The function creates spatial dataframe of normalized soil texture proportions. They are normalized to 100 percent

Usage
createTexturedata(clay,silt,sand)

Arguments

- clay  : clay proportion of soil texture in percent
- silt  : silt proportion of soil texture in percent
- sand  : sand proportion of soil texture in percent
Details

the input data of soil texture proportions are imported into R as spatial raster or dataframe. They need to have uniform coordinate reference system (CRS) and same pixel size (resolution) if in raster map format. The sum of the proportions should be close to 100 per cent for each row.

Value

The output is a spatial pixel dataframe of normalized soil texture proportions (for each pixel).

Note

It’s important to ensure the input data does not have negative values nor add up to far below or above 100 per cent. It’s also important to adhere to the order of the input data: clay, silt, sand.

```

---

depthSuit

A function for assessing soil depth suitability requirements for certain crops

Description

This function determines the suitability classes for soil depth requirements of selected agricultural crops.

Usage

```r
depthSuit(value, crop)
```

Arguments

<table>
<thead>
<tr>
<th>value</th>
<th>Input soil depth in cm</th>
</tr>
</thead>
<tbody>
<tr>
<td>crop</td>
<td>The crop of interest for which soil depth suitability class is sought</td>
</tr>
</tbody>
</table>
Details

The input value can be map or just a numerical entry of soil depth in cm

Value

The output is soil depth suitability class for the crop. The output is integer value for suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

###
drainageSuit

A function for assessing drainage suitability requirements for certain crops

Description

This function determines the suitability classes for drainage requirements for selected agricultural crops
Usage

    drainageSuit(value, crop)

Arguments

    value          Input drainage class code
    crop           The crop of interest for which drainage suitability class is sought.

Details

    The input value can be a map or an integer of drainage class code. The textural class code is obtained using classCode("drainage")

Value

    The output is drainage suitability class for the crop. The output is an integer value for suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

Note

    If the input value is raster map, then the output will also be a raster map of drainage suitability for the crop of interest

ECconversion1

Description

This function converts electrical conductivity measurements of a soil solution to that of soil paste extract. It considers the influence of texture, organic matter content, and clay content on electrical conductivity conversion. These factors and ratio of soil:water mix for the solution and conversion method must be indicated.

Usage

ECconversion1(ec, oc, clay, texture, soilsolution, method)

Arguments

ec measured electrical conductivity of the soil solution in dS/m
oc organic matter content of the soil in percent
clay clay content of the soil in percent
texture soil textural class according to USDA or its equivalent. Texture class is given in terms of class codes as given in classnames("texture")
soilsolution ratio of soil:water mix when electrical conductivity was measured. Example is 1:1, 1:2, etc. The default is 1:1
method method for converting electrical conductivity of the soil:water mix to that of the soil paste extract. The methods included are FAO, sonmez, and hogg. The default is FAO

Details

This function considers the influence of texture, clay content, organic matter content, and soil-water solution on conversion of electrical conductivities

Value

electrical conductivity equivalent for saturated soil extract in dS/m

Author(s)

Christian Thine Omuto
ECconversion2

**References**

**See Also**

**Examples**

```r
library(sp)
library(raster)
ECconversion1(7.31,1.02,22.1,5,"1:2.5", "FAO")
ec=suitabinput["ec"]
soc=nutrindicator["soc"]
clay=textureinput["clay"]
texture=suitabinput["texture"]
newmap=ec
newmap$ECe=ECconversion1(ec$ec,soc$soc,clay$clay,texture$texture,"1:2.5", "FAO")
spplot(newmap["ECe"], main="Equivalent ECse")
```

**ECconversion2**

*A function for correcting electrical conductivity of soil solution to that of saturated paste extract for all textural classes*

**Description**

This function converts electrical conductivity measurements of soil solution to that of soil paste extract. The ratio of soil:water mix for the solution and conversion method must be indicated

**Usage**

ECconversion2(ec, soilsolution, method)

**Arguments**

- **ec**: measured electrical conductivity of the soil solution in dS/m
- **soilsolution**: ratio of soil:water mix when electrical conductivity was measured. Example is 1:1, 1:2, etc. The default is 1:1
- **method**: method for converting electrical conductivity of the soil:water mix to that of the soil paste extract. The methods included are USDA, landon, kargas, ozkan, and hogg. The default is USDA
Details
This function assumes no influence of texture, clay content, etc on the conversion of electrical conductivities

Value

electrical conductivity equivalent for saturated soil extract in dS/m

Author(s)

Christian Thine Omuto

References

See Also

ECconversion1, saltClass, saltRating

Examples

library(sp)

str(newmap$salinity)
spplot(newmap["salinity"])

ECconversion3

A function for developing own conversion model

Description

This function enables development of own function for converting soil assessment indicators to those determined from the standard saturated soil paste

Usage

ECconversion3(x, A, B, method)
Arguments

x input predictor value
A A location parameter representing the value of target variable when the predictors are minimal (or the y-intercept)
B Rate parameter representing the rate of change of the target variable with the predictor (or the slope)
method model relationship between target and predictor variables

Details

model for the relationship between target and predictor variables can be "linear", "power", "exponential", "log". Default is "linear"

Value

model object containing predictive parameters of the conversion model

**ECconversion4**  

*A function for converting salt measurements into equivalent electrical conductivity in dS/m*

---

**Description**

This function allows approximate conversion of other soil salt measurements into equivalent electrical conductivity (EC) in dS/m. These measurements include total soluble salts (TSS), total dissolved solids (TDS) and EC in mmho/cm.

**Usage**

```
ECconversion4(x, target)
```

**Arguments**

- `x` is a numeric value of salt to convert to equivalent EC in dS/m
- `target` is the target salt measurement to be converted into equivalent electrical conductivity (EC) in dS/m. It can be TDS (mg/l or ppm), TSS (mmol/l), EC in (mmho/cm).

**Details**

The target is specified as TDS or TSS or mmho or Sodium Adsorption Ratio (SAR).

**Value**

The output is a numeric value of equivalent electrical conductivity (EC) in dS/m.

**Note**

TDS should be given in mg/l or ppm. TSS should be given in mmol/l. The function does not convert salt values between different measurement methods.

**ECSuit**

*A function for assessing Electrical Conductivity suitability requirements for certain crops*

---

**Description**

This function determines the suitability classes for Electrical Conductivity requirements for selected agricultural crops.

**Usage**

`ECSuit(value, crop)`

**Arguments**

- **value**: Input electrical conductivity in dS/m.
- **crop**: The crop of interest for which Electrical Conductivity suitability class is sought.

**Details**

The input value can be map or just a numerical entry of electrical conductivity (ECe) of saturated paste extract or its equivalent in dS/m.

**Value**

The output is EC suitability class for the crop. The output is integer value for suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable.

**Note**

If the input value is raster map, then the output will also be a raster map of Electrical Conductivity suitability for the crop of interest.

---

**erodFUN**  
*A function to estimate soil erodibility factor*

**Description**

A function to determine soil erodibility factor from a choice of different erodibility models.

**Usage**

```r
erodFUN(sand,silt,clay,OC,texture,Struct,method)
```

**Arguments**

- `sand`: sand proportion (percent) of the soil texture
- `silt`: silt proportion (percent) of the soil texture
- `clay`: clay proportion (percent) of the soil texture
- `OC`: soil carbon content (percent)
- `texture`: soil texture code representing the USDA soil textural class. Use `classnames("texture")` to insert the correct texture code.
- `Struct`: soil structure code representing the soil structure class. Use `classnames("structure")` to insert the correct structure code.
- `method`: method for determining soil erodibility. The following methods are included: WSmith, Yang, Renard, Bouyoucos, Denardin, Wang, Wisch1, Wisch2, Sharpley, Cheng, Auer.

**Value**

soil erodibility factor ranging between 0 and 1
erodibilityRisk

A function to determine soil erodibility risk

Description

This function classifies soil erodibility factor into classes of risk to erosion

Usage

erodibilityRisk(x)

Arguments

x  soil erodibility factor value between 0 and 1

Details

Erodibility factor ranges between 0 (lowest risk) to 1 (highest risk)
erosivFUN

Value

erodibility risk classes

spplot(x[“erodib”])

erosivFUN

A function to estimate rainfall erosivity from annual rainfall amounts

Description

This function assumes an algebraic relationship between annual rainfall amounts and rainfall erosivity. The relationship has constants that may depend of certain regions.

Usage

erosivFUN(rain,A,B, model)
Arguments

- `rain`: annual rainfall amounts in mm or Fourier index of rainfall
- `A`: independent constant of the algebraic relationship between rainfall mounts and erosive energy (Energy = A + B * rainfall)
- `B`: rainfall coefficient of the algebraic relationship between rainfall mounts and erosive energy (Energy = A + B * rainfall)
- `model`: model defining the algebraic relationship between rainfall mounts and erosive energy. The model can be linear, power, logarithmic, Fourier, and exponential

Value

- `rainfall erosivity in MJ mm/ha/hr/yr`

Author(s)

Christian Thine

References

erodFun, sloplenFun

Examples

```r
erosivFUN(587, 151, 0.63, "linear")
```

ESPSuit

A function for assessing Exchangeable Sodium Percent (ESP) suitability requirements for certain crops

Description

This function determines the suitability classes for ESP requirements of selected agricultural crops

Usage

```r
ESPSuit(value, crop)
```

Arguments

- `value`: Input Exchangeable Sodium Percent (ESP).
- `crop`: The crop of interest for which ESP suitability class is sought.
The input value can be map or just a numerical value of Exchangeable Sodium Percent (ESP).

The output is ESP suitability class for the crop. The output is integer value for suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

Note

If the input value is raster map, then the output will also be a raster map of ESP suitability for the crop of interest

Christian Thine Omuto

See Also

tempSuit, PHSuit, rainSuit

Examples

```r
ESPSuit(8.6,"broccoli")
```

This function establishes graphical representation of the landscape feature in the sample points. An approximation of Kolmogorov-Smirnov similarity test (D-statistic) between the sampled feature distribution and the population feature distribution is also given.

Usage

```r
featureRep(fgrid,df )
```
Arguments

fgrid  raster grid of the landscape feature
df     dataframe of sampled locations with similar coordinate reference system (CRS) as the input raster map

Details

The sampled points should have the same coordinate system as the landscape feature (raster map). The function extracts the raster map values, attaches them to the sample points, and creates histogram distributions: one for the feature map as contained in the sample points and another as contained in the raster map.

Value

Histograms on back-to-back showing distribution of the landscape feature in the sampled points and on the map for similarity comparison

Note

The input points dataframe and raster map must have similar coordinate reference system.

fertilityRating

A function for determining soil fertility levels for given soil property
(fertility indicator)

Description

This function determines the fertility levels given values of a soil property.

Usage

fertilityRating(value, indicator = "nitrogen")

Arguments

value numerical value of soil property
indicator soil property as fertility indicator

Details

The units for input values are: nitrogen (percent), phosphorus (mg/kg); potassium (cmol(+)/kg); carbon (percent); iron (mg/kg); CEC (cmol(+)/kg)

Value

soil fertility class code for the given soil property (fertility indicator)

imageIndices

A function for developing remote sensing indices for soil assessment

Description

The function determines commonly used remote sensing indices with relationship with soil surface or vegetation cover characteristics.

Usage

imageIndices(blue, green, red, nir, swir1, swir2, index)
Arguments

- **blue**: blue image band with wavelength range: 0.452-0.512 µm
- **green**: green image band with wavelength range: 0.533-0.59 µm
- **red**: red image band with wavelength range: 0.636-0.673 µm
- **nir**: NIR image band with wavelength range: 0.851-0.879 µm
- **swir1**: SWIR image band with wavelength range: 1.566-1.651 µm
- **swir2**: SWIR image band with wavelength range: 2.107-2.294 µm
- **index**: index from combination of image bands such as NDVI, SAVI, SI, etc. The default is NDVI.

Details

The indices included in the package are: NDVI, NDSI (for salinity), NDSnI (for snow), SI1, SI2, SI3, SI4, SI5, SI6, SAVI, VSSI, NDSI, SR, CRSI, BI, ROCK

Value

dimensionless remote sensing index

LGPSuit  

A function for assessing Length of Growing Period (LGP) suitability requirements for certain crops

Description

This function determines the suitability classes for length of growing period (LGP) requirements for selected agricultural crops

Usage

LGPSuit(value, crop)

Arguments

value  
Input length of growing period (LGP) in days.

crop  
The crop of interest for which length of growing period (LGP) suitability class is sought.

Details

The input value can be map or an integer value of LGP in days

Value

The output is LGP suitability class for the crop. The output is an integer for suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

Note

If the input value is raster map, then the output will also be a raster map of LGP suitability for the crop of interest

Author(s)

Christian Thine Omuto

NPPmodel

A function for calculating net primary production using air temperature and mean rainfall amount

Description

This is an empirical function for deriving net primary production using climatic variables (mean temperature and rainfall amounts)

Usage

NPPmodel(rain, temperature, model)

Arguments

- **rain**: total annual rainfall amount in mm
- **temperature**: average annual air temperature amount in degrees Celsius
- **model**: model for calculating net primary production. Included models in the function are Miami, Schurr, and NCEAS

Details

This function is based on empirical models for calculating annual net primary production (NPP) of dry matter

Value

Net primary production (NPP) of dry matter in grams per square meter per year

See Also

tempSuit, PHSuit, rainSuit

Examples

```r
library(sp)
library(maptools)
LGPSuit(138,"cotton")
newmap = data.frame(LGP = c(1:6,158,160,211),
                   lon = c(1,1,1,2,2,2,3,3,3),
                   lat = c(rep(c(0, 1.5, 3),3)))
coordinates(newmap) = ~lon+lat
gridded(newmap) = TRUE
newmap = as(newmap, "SpatialGridDataFrame")
newmap$LGPmillet=LGPSuit(newmap$LGP,"millet")
spplot(newmap["LGPmillet"], main="LGP suitability map for finger millet")
```
Note
This empirical function estimates annual NPP in g/m2/year. It is a general model for all land cover types. It may be necessary to adjust it for certain cover types or geolocations

<table>
<thead>
<tr>
<th>nutrient</th>
<th>Sample data of decision ranking table for mapping soil nutrient condition</th>
</tr>
</thead>
</table>

Description
This is an 11-factor table of decision ranking of soil nutrient indicators

Usage
data("nutrient")

Format
A dataframe with 11 factors for pairwise decision ranking of soil nutrient indicators.

Details
The ranks are the reciprocals of Saaty’s scale of relative importance which are between 1 and 9
Source

Hypothetical data of rank between soil nutrient indicators

Examples

data(nutrient)
str(nutrient)
plot(nutrient)

data(nutrindicator)
str(nutrindicator)

#spplot(nutrindicator["nitrogen"])
A pedotransfer function to predict electrical conductivity or any other soil property using other soil properties

Description
This generic pedo-transfer function is used to approximate EC values from other existing and easy-to-measure soil data

Usage
```r
pedoTransfer(method="linear", df, ...)
```

Arguments
- `method`: modelling method to link EC and other soil predictors (properties). Default method is linear
- `df`: dataframe containing measured EC and predictors of soil properties
- `...`: names of measured EC and list of predictors (soil properties) separated by comma. The names should match the variables in the accompanying dataframe

Details
This generic model can be used even with other soil properties. For example, it can be used to predict porosity from bulk density, carbon, and texture components as long as they are in the database and have known/suspected relationship

Value
model for predicting EC given similar input data

Note
This function can also be used to predict EC from apparent electrical conductivity of bulk soil, texture, and other important soil properties

permeabilityClass A function to determine permeability class

Description
This function determines the soil permeability classes according to the USDA soil textural classes

Usage

permeabilityClass(texture)

Arguments

  texture soil textural class code

Details
  Soil textural class code is obtained using classnames("texture")

Value

  permeability class code
PHSuit

PHSuit A function for assessing pH suitability requirements for certain crops

Description
This function determines the suitability classes for soil pH requirements for selected agricultural crops

Usage
PHSuit(value, crop)

Arguments
value Input soil pH.
crop The crop of interest for which soil pH suitability class is sought.

Details
The input value can be map or just a numerical entry of soil pH of a saturated paste extract
Value

The output is pH suitability class for the crop. The output is integer value of suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

Note

If the input value is raster map, then the output will also be a raster map of pH suitability for the crop of interest

---

**predUncertain**

*Function to develop spatial map of modelling uncertainty using bootstrap approach*

Description

This functions uses bootstrap approach to estimate spatial maps of modelling prediction interval width and standard deviation

Usage

```
predUncertain(indata,fgrid, k, z, model="rf")
```
predUncertain

Arguments

- **indata**: one column input spatial dataframe containing the target soil variable or its transformation
- **fgrid**: Input grid or raster stack containing predictors set for the target soil variable
- **k**: Set limit for number of realizations/simulations for bootstrap algorithm
- **z**: Confidence interval level in percent (for example 95)
- **model**: The model for predicting target soil variable using the predictors (for example linear)

Details

One-variable input dataframe is preferred or at least the first column should have the target soil variable to predict. It should not contain NAs. The number of realizations k need not be too high because the software multiplies it exponentially and may slow down the computing process if set to a high value. For example k=5 will results into more than 40 realizations created.

Value

- a two-layer raster stack map of prediction width and standard deviation

Note

The input dataframe and predictors need to have similar coordinate reference system (CRS). In addition, the input dataframe should not have missing entrie (NAs).

plot(pred_uncert)
```
rainSuit

A function for assessing rainfall suitability requirements for certain crops

Description

This function determines the suitability classes for rainfall requirements of selected agricultural crops.

Usage

rainSuit(value, crop)

Arguments

value
Input rainfall amounts in mm.
crop
The crop of interest for which rainfall suitability class is sought.

Details

The input value can be map or just numerical entry of annual rainfall amount in mm.

Value

The output is rainfall suitability class for the crop. The output is an integer for suitability class: 1-highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

Note

This function assumes rainfall as the source of water for crop development.

**reclassifyMap**

A function for re-classifying raster maps based on input look-up table

**Description**

This function re-classifies an input raster maps based on input look-up table that specifies transition from map classes (or range of classes) to a new class (or range of classes)

**Usage**

`reclassifyMap(fgrid, df)`

**Arguments**

- `fgrid`  
  Input raster map to be reclassified

- `df`  
  Input look-up table for re-classification

**Details**

The look-up table should have at least two columns in which the first column contains the classes in the input map and the second column contains the new classes to be assigned

**Value**

The output is a reclassified raster map

spplot(newmap["depth"])
```

---

regmodelSuit  

A function for guiding selection of prediction model for modelling soil condition

---

Description

This function evaluates suitability of most prediction models in mapping soil condition using a set of predictors.

Usage

```r
regmodelSuit(df, ...)
```

Arguments

- `df`  
  a dataframe of target soil property and its predictors
- `...`  
  name of the target soil variable to predict and names of its predictors

Details

The name of the target soil variable to predict and names of its predictors are separated by commas and are similar to column names of the corresponding variables in the supplied dataframe. The name of the target soil variable starts the list and followed by the names of its predictors. For example, if the dataframe has EC, landcover, DEM, Slope, NDVI, etc., then the input could be (soil, EC, landcover, DEM, Slope, NDVI, etc.).

Value

A table of model statistics such as root mean square error (RMSE), mean absolute error (MAE), r-squared (R2) and Nash-Sutcliffe coefficient of efficiency (NSE) for the popular models in digital soil mapping.

Note

The function carries 5-fold cross-validation. Sometimes it may give a warning of missing resample performance with some models. It's important to ensure no NA in the data used for modelling.

RotCmoistcorrection  A function for estimating moisture effects in RothC carbon turnover modelling

Description
This function estimates the scalar constant representing the moisture effects in RothC carbon turnover modelling in the soil

Usage
RotCmoistcorrection(P, E, S.Thick, clay, pE, fk)

Arguments
P  the total rainfall amount in mm
E  the total evapotranspiration amounts in mm. It can be pan evapotranspiration or potential evapotranspiration rate
S.Thick  thickness of soil depth in cm (measured from the soil surface)
clay  clay content in percent
pE  proportion of pan evapotranspiration representing potential evapotranspiration rate.
fk  A constant to correct for soil cover. For bare soil, fk=1.8 and for soil with cover, fk=1
Details

E can be given as pan evapotranspiration or potential evapotranspiration. If potential evapotranspiration is used for E, then pE = 1 and if pan evapotranspiration is used for E then pE = 0.75.

Value

A scalar constant for moisture effects on carbon decomposition rates

Note

This function can be used with monthly or annual input data to produce time-dependent scalars

```
RotCtempcorrection  A function for estimating temperature effects in organic matter decomposition rates in the soil

Description

This function estimates the scalar constant for temperature effects in RothC carbon turnover modelling in the soil.

Usage

RotCtempcorrection(temperature)

Arguments

temperature  mean air temperature in degrees Celsius

Details

mean air temperature can be monthly or annual mean temperature

Value

A scalar constant for temperature effects on carbon decomposition rates

Note

This function can be used with monthly or annual input data to produce time-dependent scalars. The function works with temperatures greater than -18.2 degrees Celsius.

airTemp=22.1
RotCtempcorrection(airTemp)
```

saltClass

A function to classify types of salt-affected soils using EC, PH, and ESP

Description

This function determines the major classes of salt-affected soils using Electrical Conductivity (EC), soil reaction (pH), and Exchangeable Sodium Percent (ESP) according to FAO or USDA classification schemes.

Usage

```r
saltClass(ec, ph, ESP, criterion="FAO")
```

Arguments

- `ec`: Electrical Conductivity in dS/m of saturated soil paste extract or its equivalent
- `ph`: soil reaction (pH)
- `ESP`: Exchangeable Sodium Percent
- `criterion`: The criterion to use for classifying the soil problem. Either FAO or USDA can be selected

Value

saltClass returns integer classes of salt problems in the soil. The classes are 1, 2, 3, 4, 5 corresponding to None, Saline, Saline-sodic, Sodic, and Alkaline categories.

Note

ESP is mandatory when using this function. The "error: 1 * ESP : non-numeric argument to binary operator" is flagged when ESP entry is missing. In case ESP is missing, saltRating is suggested.

Author(s)

Christian Thine Omuto
**saltRating**  

A function for classifying salt-affected soils using EC and PH only

**Description**

This function determines classes of salt-affected soils using Electrical Conductivity and pH according to FAO or USDA salt classification schemes

**Usage**

```r
saltRating(ec, ph, criterion="FAO")
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ec</td>
<td>Electrical Conductivity in dS/m of saturated soil paste extract or its equivalent</td>
</tr>
<tr>
<td>ph</td>
<td>soil reaction (pH)</td>
</tr>
<tr>
<td>criterion</td>
<td>The method to use for classifying salt-affected soil. Either FAO or USDA can be selected</td>
</tr>
</tbody>
</table>
Value

The output is an integer value for soil salt class. The class name for any integer code is obtained from classCode function.

Note

This function gives approximate classification. A better classification is achieved when indicator of sodium ions is included (e.g. ESP).

**saltSeverity**

*A function to classify severity levels of salt problems in the soil*

**Description**
This function classifies degree/severity of salt problems in the soil according to EC, pH and ESP levels

**Usage**
saltSeverity(ec, ph, ESP, method = "FAO")

**Arguments**
- ec: electrical conductivity in dS/m of saturated soil paste extract or its equivalent
- ph: soil reaction (pH)
- ESP: Exchangeable sodium percent
- method: classification method for severity/degree of salt problems. FAO, USDA and Amrhein methods are included. Default method is FAO

**Details**
This function requires input EC, pH and ESP values to process the classification. They can be maps or numerical entries

**Value**
Integer classes of ranging between 1-17. The names of integer codes are obtained using classCode function

**Note**
The function strictly requires input EC, pH, and ESP

sloplenFUN

A function for estimating slope-length factor for soil erosion

Description

The function estimates slope length factor for erosion risk assessment. It has options for choosing different algorithms

Usage

```
sloplenFUN(ls,slope,method)
```

Arguments

- `ls` length of slope in metres
- `slope` slope of land in degrees
- `method` method for deriving slope-length factor. The methods included are: WSmith, Renard, Remortel, Zhang, Nearing, Smith, Foster, David, Morgan, and Moore.
SOCSuit

Details

Slope (degrees) and length of slope (metres) are relief parameters in erosion risk assessment.

Value

a dimensionless quantity of slope-length factor of erosion risk

Note

The slope must be in degrees. The warning given is a reminder to that the slope is given in degrees

The input value can be map or just a numerical entry of stoniness in percent.

**Value**

The output is stoniness suitability class for the crop. The output is an integer value for suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable.

**Note**

Output raster map of stoniness for the crop of interest is given if the input value is raster map.

stoneSuit(15,"grape")

suitability  A function to determine soil suitability for agricultural crops

Description
This function determines soil condition classes (such as suitability, fertility, etc.) given a set of indicators.

Usage
suitability(df, data)

Arguments
- **df**: normalized pairwise decision (nxn) matrix for comparing n soil suitability (condition) factors
- **data**: a (nxm) matrix of n suitability (condition) factors for m locations (pixels)

Value
A vector of soil suitability (condition) class between 0 and 5.

Note
It's important to normalize and assess the adequacy of the decision matrix before using this function.

suitabilityClass

A function to determine suitability classes for given indicator values

Description

This function determines the suitability class to which a given indicator value falls based on the crop requirement

Usage

```r
suitabilityClass(value, crop, factor)
```

Arguments

- **value**: Input indicator value.
- **crop**: The crop of interest for which suitability is determined.
- **factor**: The suitability factor for crop requirement. Example factors include: rain, slope, carbonate, EC, ESP, depth, pH, temperature,
Value

The output is rainfall suitability class for the crop. The output is integer value for suitability class:
1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

Note

This function assumes rainfall as the source of water for crop development. The input slope value must be in degrees

surveyPoints A function to generate georeferenced locations for monitoring soil conditions

Description

This function uses stratified random sampling to generate georeferenced locations for monitoring soil conditions

Usage

surveyPoints(soilmap, scorpan, conditionclass, mapproportion)

Arguments

soilmap input classified map of soil condition
scorpan number of scorpan factors that generated teh soil condition map. The range is 1-5
conditionclass reference class in the soil condition map to be monitored. The class code should be in the map
mapproportion Proportion in percent of the reference class in the soil condition map to be monitored.
surveyPoints

Details

The number of scorpan factors can be assumed but need to be with respect to the soil forming factors. The maximum possible number of factors is 5 irrespective of number of layers in each factor while the minimum number is 1. The soil condition class is the class code in the map which is to be targeted.

Value

A spatial points dataframe with projection similar to the soil condition map projection

spplot(salt, scales=list(draw=TRUE),sp.layout=list("sp.points",n_points,pch=8,col="cyan"))
```
**tempSuit**

A function for assessing temperature suitability requirements for certain crops

---

**Description**

This function determines the suitability classes for temperature requirements of selected agricultural crops.

**Usage**

tempSuit(value, crop)

**Arguments**

- **value**: Input temperature in degrees Celsius.
- **crop**: The crop of interest for which temperature suitability class is sought.

**Details**

The input value can be map or just a numerical entry of temperature in degrees Celsius.

**Value**

The output is temperature suitability class for the crop. The output is integer value for suitability class: 1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable.

textureinput

Sample texture dataset for mapping soil texture

Description

Sample dataset for assessing soil texture

Usage

data("textureinput")

Format

The format is: Formal class 'SpatialGridDataFrame' [package "sp"] with 4 slots ..@ data: 'data.frame':
: Formal class 'GridTopology' [package "sp"] with 3 slots .. ..@ cellcentre.offset: Named num [1:2]
383216 3341506 .. ..@ cells.dim: int [1:2] 130 130 ..@ bbox: num [1:2, 1:2] 383038 3341327 429478 3387767 .. ..@ proj4string:
: Formal class 'CRS' [package "sp"] with 1 slot .. ..@ projargs: chr "+proj=utm +zone=41 +datum=WGS84 +units=m +no_defs"

Examples

data(textureinput)
summary(textureinput)

textureSuit

A function for assessing texture suitability requirements for certain crops

Description

This function determines the suitability classes for texture requirements of selected agricultural crops

Usage

textureSuit(value, crop)
**Arguments**

- **value**: Input textural class code.
- **crop**: The crop of interest for which texture suitability class is sought.

**Details**

The input value can be map or just a numerical entry of textural class code. The textural class code is obtained using `classCode("texture")`

**Value**

The output is texture suitability class for the crop. The output is integer value for suitability class:
1 - highly suitable; 2 - moderately suitable; 3 - marginally suitable; 4 - currently not suitable; 5 - not suitable

**Note**

If the input value is raster map, then the output will also be a raster map of texture suitability for the crop of interest
