Package ‘spatialRF’

August 19, 2022

Title Easy Spatial Modeling with Random Forest
Version 1.1.4
URL https://blasbenito.github.io/spatialRF/
BugReports https://github.com/BlasBenito/spatialRF/issues/
Description Automatic generation and selection of spatial predictors for spatial regression with Random Forest. Spatial predictors are surrogates of variables driving the spatial structure of a response variable. The package offers two methods to generate spatial predictors from a distance matrix among training cases: 1) Moran’s Eigenvector Maps (MEMs; Dray, Legendre, and Peres-Neto 2006 <DOI:10.1016/j.ecolmodel.2006.02.015>): computed as the eigenvectors of a weighted matrix of distances; 2) RFsp (Hengl et al. <DOI:10.7717/peerj.5518>): columns of the distance matrix used as spatial predictors. Spatial predictors help minimize the spatial autocorrelation of the model residuals and facilitate an honest assessment of the importance scores of the non-spatial predictors. Additionally, functions to reduce multicollinearity, identify relevant variable interactions, tune random forest hyperparameters, assess model transferability via spatial cross-validation, and explore model results via partial dependence curves and interaction surfaces are included in the package. The modelling functions are built around the highly efficient ‘ranger’ package (Wright and Ziegler 2017 <DOI:10.18637/jss.v077.i01>).

**Description**

Computes the area under the ROC curve in models with binary responses.

**Usage**

```r
auc(o, p)
```

**Arguments**

- `o`: Numeric vector with observations, must have the same length as `p`.
- `p`: Numeric vector with predictions, must have the same length as `o`.

**Value**

Numeric, AUC value.
Examples

```r
if(interactive()){
  out <- auc(
    o = c(0, 0, 1, 1),
    p = c(0.1, 0.6, 0.4, 0.8)
  )
}
```

Description

Computes the correlation matrix among a set of predictors, orders the correlation matrix according to a user-defined preference order, and removes variables one by one, taking into account the preference order, until the remaining ones are below a given Pearson correlation threshold. **Warning:** variables in `preference.order` not in `colnames(x)`, and non-numeric columns are removed silently from `x` and `preference.order`. The same happens with rows having NA values (`na.omit()` is applied). The function issues a warning if zero-variance columns are found.

Usage

```r
auto_cor(
  x = NULL,
  preference.order = NULL,
  cor.threshold = 0.5,
  verbose = TRUE
)
```

Arguments

- **x**
  A data frame with predictors, or the result of `auto_vif()` Default: NULL.

- **preference.order**
  Character vector indicating the user’s order of preference to keep variables. Doesn’t need to contain If not provided, variables in x are prioritised by their column order. Default: NULL.

- **cor.threshold**
  Numeric between 0 and 1, with recommended values between 0.5 and 0.9. Maximum Pearson correlation between any pair of the selected variables. Default: 0.50

- **verbose**
  Logical. if TRUE, describes the function operations to the user. Default:: TRUE

Details

Can be chained together with `auto_vif()` through pipes, see the examples below.
Value

List with three slots:

- `cor`: correlation matrix of the selected variables.
- `selected.variables`: character vector with the names of the selected variables.
- `selected.variables.df`: data frame with the selected variables.

See Also

`auto_vif()`

Examples

```r
if(interactive()){
  #load data
data(plant_richness_df)

  #on a data frame
  out <- auto_cor(x = plant_richness_df[, 5:21])
  #getting the correlation matrix
  out$cor
  #getting the names of the selected variables
  out$selected.variables
  #getting the data frame of selected variables
  out$selected.variables.df

  #on the result of auto_vif
  out <- auto_vif(x = plant_richness_df[, 5:21])
  out <- auto_cor(x = out)

  #with pipes
  out <- plant_richness_df[, 5:21] %>%
        auto_vif() %>%
        auto_cor()
}
```
auto_vif

Description

Selects predictors that are not linear combinations of other predictors by using computing their variance inflation factors (VIF). Allows the user to define an order of preference for the selection of predictors. **Warning**: variables in `preference.order` not in `colnames(x)`, and non-numeric columns are removed silently from `x` and `preference.order`. The same happens with rows having NA values (`.na.omit()` is applied). The function issues a warning if zero-variance columns are found.

Usage

```r
code
```

Arguments

- `x` A data frame with predictors or the result of `auto_cor()`. Default: `NULL`.
- `preference.order` a character vector with columns names of `x` ordered by the user preference, Default: `NULL`.
- `vif.threshold` Numeric between 2.5 and 10 defining the selection threshold for the VIF analysis. Higher numbers result in a more relaxed variable selection. Default: 5.
- `verbose` Logical. if `TRUE`, describes the function operations to the user. Default: `TRUE`.

Details

This function has two modes of operation:

- 1. When the argument `preference.order` is `NULL`, the function removes on each iteration the variable with the highest VIF until all VIF values are lower than `vif.threshold`.
- 2. When `preference.order` is provided, the variables are selected by giving them priority according to their order in `preference.order`. If there are variables not in `preference.order`, these are selected as in option 1. Once both groups of variables have been processed, all variables are put together and selected by giving priority to the ones in `preference.order`. This method preserves the variables desired by the user as much as possible.

Can be chained together with `auto_cor()` through pipes, see the examples below.

Value

List with three slots:

- `vif`: data frame with the names of the selected variables and their respective VIF scores.
- `selected.variables`: character vector with the names of the selected variables.
- `selected.variables.df`: data frame with the selected variables.
Define a beowulf cluster

**Description**

Defines a Beowulf cluster from the IPs of the machines in the cluster, the number of cores of each machine, and the user name. The returned cluster has to be registered with `doParallel::registerDoParallel()`.

**Usage**

```r
beowulf_cluster(
  cluster.ips = NULL,
  cluster.cores = NULL,
  cluster.user = Sys.info()$"user",
  cluster.port = "11000",
  outfile = NULL
)
```
Arguments

cluster.ips  Character vector with the IPs of the machines in the cluster. The first machine will be considered the main node of the cluster, and will generally be the machine on which the R code is being executed. Default: NULL.

cluster.cores  Numeric integer vector, number of cores on each machine. Default: NULL.

cluster.user  Character string, name of the user (should be the same throughout machines), Defaults to the current system user.

cluster.port  Character, port used by the machines in the cluster to communicate. The firewall in all computers must allow traffic from and to such port. Default: "11000"

outfile  Where to direct the messages provided by the workers. When working on a local computer, "" prints the worker’s messages in the console. A text file path will append worker’s messages on the given file. Default: /dev/null en Linux and nul: on windows.

Value

A list ready to be used as input for the spec argument of the function makeCluster.

Examples

if(interactive()){
    beowulf.cluster <- beowulf_cluster(
        cluster.ips = c("10.42.0.1", "10.42.0.34", "10.42.0.104"),
        cluster.cores = c(7, 4, 4),
        cluster.user = "blas",
        cluster.port = "11000"
    )

doParallel::registerDoParallel(cl = beowulf.cluster)

#PARALLELIZED foreach LOOP HERE

parallel::stopCluster(cl = beowulf.cluster)
}

beowulf_cluster
case_weights

Generates case weights for binary data

Description

When the data is binary, setting the argument case.weights helps to minimize the issues produced by class imbalance. This function takes a binary response variable and returns a vector of weights populated with the values 1/#zeros and 1/#ones. It is used internally by the function rf().

Usage

case_weights(data = NULL, dependent.variable.name = NULL)

Arguments

data Data frame with a response variable and a set of predictors. Default: NULL
dependent.variable.name Character string with the name of the response variable. Must be in the column names of data. Default: NULL

Value

A vector with a length equal to nrow(data) with the respective weights of the cases.

Examples

if(interactive()){  
data <- data.frame(  
  response = c(0, 0, 0, 1, 1)  
)

case_weights(  
data = data,  
dependent.variable.name = "response"  
)
}

default_distance_thresholds

Default distance thresholds to generate spatial predictors

Description
Generates four distance thresholds, from 0 to max(distance.matrix)/2.

Usage

default_distance_thresholds(distance.matrix = NULL)

Arguments

distance.matrix
Distance matrix. Default: NULL.

Value
A numeric vector with distance thresholds.

Examples

if(interactive()){  
  #loading example distance matrix  
data(distance_matrix)  
  #computing set of default distance thresholds  
default_distance_thresholds(distance_matrix)
}

distance_matrix

Matrix of distances among ecoregion edges.

Description
Distance matrix (in km) among the edges of the American ecoregions described in the plant_richness_df dataset.

Usage

data(distance_matrix)
**double_center_distance_matrix**

**Format**

A numeric matrix with 227 rows and columns.

**See Also**

plant_richness_df

double_center_distance_matrix

---

**Description**

Generates a double-centered matrix (row and column means are zero) from the weights of a distance matrix (see weights_from_distance_matrix()) and a distance threshold. This is a required step before the computation of Moran’s Eigenvector Maps.

**Usage**

```r
double_center_distance_matrix ( distance.matrix = NULL, distance.threshold = 0 )
```

**Arguments**

- `distance.matrix` Distance matrix. Default: `NULL`.
- `distance.threshold` Numeric, positive, in the range of values of `x`. Distances below this value in the distance matrix are set to 0. Default: 0.

**Value**

A double-centered matrix of the same dimensions as `x`.

**See Also**

weights_from_distance_matrix(), mem(), mem_multithreshold()

**Examples**

```r
if(interactive()){

#loading the distance matrix
data(distance_matrix)

x <- double_center_distance_matrix(}
```
filter_spatial_predictors

Removes redundant spatial predictors

Description

Removes spatial predictors that are pair-wise correlated with other spatial predictors (which happens when there are several close distance thresholds), and spatial predictors correlated with non-spatial predictors.

Usage

filter_spatial_predictors(
  data = NULL,
  predictor.variable.names = NULL,
  spatial.predictors.df = NULL,
  cor.threshold = 0.5
)

Arguments

data               Data frame with a response variable and a set of predictors. Default: NULL
predictor.variable.names
                      Character vector with the names of the predictive variables. Every element of this vector must be in the column names of data. Default: NULL
spatial.predictors.df
                      Data frame of spatial predictors.
cor.threshold       Numeric between 0 and 1, maximum Pearson correlation between any pair of the selected variables. Default: 0.50

Value

A data frame with non-redundant spatial predictors.

Examples

if(interactive()){

  #loading data
data("distance_matrix")
data("plant_richness_df")
}
get_evaluation

#computing Moran's Eigenvector Maps
spatial.predictors.df <- mem_multithreshold(
    distance_matrix = distance_matrix,
    distance.thresholds = c(0, 1000)
)

#filtering spatial predictors
spatial.predictors.df <- filter_spatial_predictors(
    data = plant_richness_df,
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    spatial.predictors.df = spatial.predictors.df,
    cor.threshold = 0.50
)

get_evaluation

Gets performance data frame from a cross-validated model

Description

Returns performance metrics produced by rf_evaluate().

Usage

generate_evaluation(model)

Arguments

model A model fitted with rf_evaluate().

Value

A data frame with evaluation scores. The following columns are shown:

- **model**: Identifies the given model. The values are "Full", (original model introduced into rf_evaluate()), "Training" (model trained on an independent training spatial fold), and "Testing" (predictive performance of the training model on an independent testing spatial fold). The performance values of the "Testing" model represent the model performance on unseen data, and hence its ability to generalize.
- **metric**: Four values representing different evaluation metrics, "rmse", "nrmse", "r.squared", and "pseudo.r.squared".
- **mean**, **sd**, **min**, and **max**: Average, standard deviation, minimum, and maximum of each metric across the evaluation (cross-validation) iterations.

See Also

rf_evaluate().plot_evaluation().print_evaluation()
**get_importance**

*Gets the global importance data frame from a model*

**Description**

Gets variable importance scores from `rf()`, `rf_repeat()`, and `rf_spatial()` models.

**Usage**

```r
get_importance(model)
```

**Arguments**

- `model` A model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`. Default: NULL

**Value**

A data frame with variable names and importance scores.
get_importance_local

See Also

rf(), rf_repeat(), rf_spatial(), plot_importance(), print_importance().

Examples

if(interactive()){
  data(plant_richness_df)
  data(distance_matrix)

  rf.model <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = 0,
    n.cores = 1,
    verbose = FALSE
  )

  x <- get_importance(rf.model)
  x
}

get_importance_local

Gets the local importance data frame from a model

Description

Gets local importance scores from rf(), rf_repeat(), and rf_spatial() models.

Usage

get_importance_local(model)

Arguments

model A model fitted with rf(), rf_repeat(), or rf_spatial(). Default: NULL

Value

A data frame with variable names and local importance scores.

See Also

rf(), rf_repeat(), rf_spatial(), plot_importance(), print_importance().
Examples

if(interactive()){
  
  # loading example data
  data(plant_richness_df)
  data(distance_matrix)
  
  # fitting a random forest model
  rf.model <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = 0,
    n.cores = 1,
    verbose = FALSE
  )
  
  # getting importance scores
  x <- get_importance_local(rf.model)
  x
}

get.moran

gets Moran's I test of model residuals

Description

Returns the Moran's I test on the residuals of a model produced by rf(), rf_repeat(), or rf_spatial().

Usage

get.moran(model)

Arguments

model A model fitted with rf(), rf_repeat(), or rf_spatial()

Value

A data frame with Moran's I test results produced by moran_multithreshold().

See Also

moran(), moran_multithreshold(), plot_moran(), print_moran().
Examples

if(interactive()){
  # loading example data
  data(plant_richness_df)
  data(distance_matrix)

  # fitting a random forest model
  rf.model <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = c(0, 1000, 2000),
    n.cores = 1,
    verbose = FALSE
  )

  # getting Moran's I of the residuals
  x <- get_moran(rf.model)
}

get_performance

get_performance

get_performance

<table>
<thead>
<tr>
<th>get_performance</th>
<th>Gets out-of-bag performance scores from a model</th>
</tr>
</thead>
</table>

Description

Returns the performance slot of an rf(), rf_repeat(), or rf_spatial() model computed on the out-of-bag data.

Usage

get_performance(model)

Arguments

model Model fitted with rf(), rf_repeat(), or rf_spatial().

Value

A data frame with four columns:

- metric Name of the performance metric.
- median Value of the performance metric. Truly a median only if the model is fitted with rf_repeat().
- median_absolute_deviation median absolute deviation (MAD), only if the model is fitted with rf_repeat(), and NA otherwise.
get_predictions

See Also

print_performance()

Examples

if(interactive()){

#loading example data
data(plant_richness_df)
data(distance_matrix)

#fitting random forest model
rf.model <- rf(  
data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",  
predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = 0,
    n.cores = 1,
    verbose = FALSE  
)

#getting model performance  
x <- get_performance(rf.model)
  
x
}

get_predictions  Gets model predictions

Description

Returns model predictions from a model fitted with rf(), rf_repeat(), or rf_spatial().

Usage

generate_predictions(model)

Arguments

  model A model produced by rf(), rf_repeat(), or rf_spatial().

Value

A vector with predictions, or median of the predictions across repetitions if the model was fitted with rf_repeat().
get_residuals

Examples

if(interactive()){

  #loading example data
data(plant_richness_df)

  #fitting a random forest model
rf.model <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    n.cores = 1,
    verbose = FALSE
  )

  #get vector of predictions
  x <- get_predictions(rf.model)
x
}

get_residuals Gets model residuals

Description

Returns the residuals of models fitted with rf(), rf_repeat(), or rf_spatial().

Usage

get_residuals(model)

Arguments

model A model fitted with rf(), rf_repeat(), or rf_spatial().

Value

A vector with model residuals, or the median of model residuals across repetitions if the model was fitted with rf_repeat().

Examples

if(interactive()){

  #load example data
data(plant_richness_df)

  #fit random forest model
```r
rf.model <- rf(
  data = plant_richness_df,
  dependent.variable.name = "richness_species_vascular",
  predictor.variable.names = colnames(plant_richness_df)[5:21],
  n.cores = 1,
  verbose = FALSE
)

# getting vector with residuals
x <- get_residuals(rf.model)
x
```

---

**get_response_curves**  
*Gets data to allow custom plotting of response curves*

**Description**

Generates and returns the data required to plot the response curves of a model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`.

**Usage**

```r
get_response_curves(
  model = NULL,
  variables = NULL,
  quantiles = c(0.1, 0.5, 0.9),
  grid.resolution = 200,
  verbose = TRUE
)
```

**Arguments**

- **model**: A model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`.
- **variables**: Character vector, names of predictors to plot. If NULL, the most important variables (importance higher than the median) in model are selected. Default: NULL.
- **quantiles**: Numeric vector with values between 0 and 1, argument `probs` of `quantile`. Quantiles to set the other variables to. Default: `c(0.1, 0.5, 0.9)`
- **grid.resolution**: Integer between 20 and 500. Resolution of the plotted curve Default: 100
- **verbose**: Logical, if TRUE the plot is printed. Default: TRUE

**Details**

All variables that are not plotted in a particular response curve are set to the values of their respective quantiles, and the response curve for each one of these quantiles is shown in the plot.
Value

A data frame with the following columns:

- **response**: Predicted values of the response, obtained with `stats::predict()`.
- **predictor**: Values of the given predictor.
- **quantile**: Grouping column, values of the quantiles at which the other predictors are set to generate the response curve.
- **model**: Model number, only relevant if the model was produced with `rf_repeat()`.
- **predictor.name**: Grouping variable, name of the predictor.
- **response.name**: Grouping variable, name of the response variable.

See Also

`plot_response_curves()`

Examples

```r
if(interactive()){
  #loading example data
data(plant_richness_df)

  #fitting random forest model
  out <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    n.cores = 1,
    verbose = FALSE
  )

  #getting data frame with response curves
  p <- get_response_curves(out)
  head(p)
}
```

---

**get_spatial_predictors**

*Gets the spatial predictors of a spatial model*

Description

Returns spatial predictors from a model fitted with `rf.spatial()` in order of importance.

Usage

```r
get_spatial_predictors(model)
```
Arguments
model A model fitted with rf_spatial().

Value
A data frame with the spatial predictors included in the model.

Examples
if(interactive()){
  #loading example data
data(distance_matrix)
data(plant_richness_df)

  #fitting spatial model
model <- rf_spatial(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = c(0, 1000),
    n.cores = 1,
    method = "mem.moran.sequential"
  )

  #getting data frame with the selected spatial predictors
spatial.predictors <- get_spatial_predictors(model)
head(spatial.predictors)
}

is_binary Checks if dependent variable is binary with values 1 and 0

Description
Returns TRUE if dependent.variable.name is a binary variable with the values 1 and 0.

Usage
is_binary(data = NULL, dependent.variable.name = NULL)

Arguments
data Data frame with a response variable and a set of predictors. Default: NULL
dependent.variable.name Character string with the name of the response variable. Must be in the column names of data. Default: NULL
Value

Logical.

Examples

if(interactive()){

  # dummy data frame
  data <- data.frame(
    response = c(0, 0, 0, 1, 1)
  )

  # checking if response is binary
  is_binary(
    data = data,
    dependent.variable.name = "response"
  )
}

make_spatial_fold

Makes one training and one testing spatial folds

Description

Used internally by `make_spatial_folds()` and `rf_evaluate()`. Uses the coordinates of a point `xy.i` to generate two spatially independent data folds from the data frame `xy`. It does so by growing a rectangular buffer from `xy.i` until a number of records defined by `training.fraction` is inside the buffer. The indices of these records are then stored as "training" in the output list. The indices of the remaining records outside of the buffer are stored as "testing". These training and testing records can be then used to evaluate a model on independent data via cross-validation.

Usage

```r
make_spatial_fold(
  data = NULL,
  dependent.variable.name = NULL,
  xy.i = NULL,
  xy = NULL,
  distance.step.x = NULL,
  distance.step.y = NULL,
  training.fraction = 0.8
)
```
Arguments

- **data**: Data frame with a response variable and a set of predictors. Default: NULL
- **dependent.variable.name**: Character string with the name of the response variable. Must be in the column names of data. Default: NULL
- **xy.i**: One row data frame with at least three columns: "x" (longitude), "y" (latitude), and "id" (integer, id of the record). Can be a row of xy. Default: NULL.
- **xy**: A data frame with at least three columns: "x" (longitude), "y" (latitude), and "id" (integer, index of the record). Default: NULL.
- **distance.step.x**: Numeric, distance step used during the growth in the x axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the x coordinates).
- **distance.step.y**: Numeric, distance step used during the growth in the y axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the y coordinates).
- **training.fraction**: Numeric, fraction of the data to be included in the training fold. Default: 0.8.

Value

A list with two slots named `training` and `testing` with the former having the indices of the training records selected from `xy`, and the latter having the indices of the testing records.

See Also

- `make.spatial.folds()`, `rf.evaluate()`

Examples

```r
if(interactive()){

  #loading example data
data(plant_richness_df)

  #getting case coordinates
  xy <- plant_richness_df[, 1:3]
colnames(xy) <- c("id", "x", "y")

  #building a spatial fold centered in the first pair of coordinates
  out <- make.spatial.fold(
    xy.i = xy[1, ],
    xy = xy,
    training.fraction = 0.6
  )

  #indices of the training and testing folds
  out$training
  out$testing
}
```
# Make spatial folds

Applies `make_spatial_fold()` to every record in a data frame `xy.selected` to generate as many spatially independent folds over the dataset `xy` as rows are in `xy.selected`.

## Usage

```r
make_spatial_folds(
  data = NULL,
  dependent.variable.name = NULL,
  xy.selected = NULL,
  xy = NULL,
  distance.step.x = NULL,
  distance.step.y = NULL,
  training.fraction = 0.75,
  n.cores = parallel::detectCores() - 1,
  cluster = NULL
)
```

## Arguments

- **data**
  - Data frame with a response variable and a set of predictors. Default: `NULL`

- **dependent.variable.name**
  - Character string with the name of the response variable. Must be in the column names of `data`. Default: `NULL`

- **xy.selected**
  - Data frame with at least three columns: "x" (longitude), "y" (latitude), and "id" (integer, id of the record). Usually a subset of `xy`. Usually the result of applying `thinning()` or `thinning_til_n()` to `xy`. Default: `NULL`.

- **xy**
  - Data frame with at least three columns: "x" (longitude), "y" (latitude), and "id" (integer, index of the record). Default: `NULL`.

- **distance.step.x**
  - Numeric, distance step used during the growth in the x axis of the buffers defining the training folds. Default: `NULL (1/1000th the range of the x coordinates)`. Please note that this parameter is likely intended to be `distance.step.x = NULL` as described in the `make_spatial_fold` function documentation, but the placeholder value does not follow the intended format or syntax.
distance.step.y
Numeric, distance step used during the growth in the y axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the y coordinates).

training.fraction
numeric, fraction of the data to be included in the growing buffer as training data, Default: 0.75

n.cores
Integer, number of cores to use for parallel execution. Creates a socket cluster with parallel::makeCluster(), runs operations in parallel with foreach and %dopar%, and stops the cluster with parallel::clusterStop() when the job is done. Default: parallel::detectCores() - 1

cluster
A cluster definition generated with parallel::makeCluster(). If provided, overrides n.cores. When cluster = NULL (default value), and model is provided, the cluster in model, if any, is used instead. If this cluster is NULL, then the function uses n.cores instead. The function does not stop a provided cluster, so it should be stopped with parallel::stopCluster() afterwards. The cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the model argument, or using the %>% pipe. Default: NULL

Value
A list with as many slots as rows are in xy.selected. Each slot has two slots named training and testing, with the former having the indices of the training records selected from xy, and the latter having the indices of the testing records.

mem

Moran’s Eigenvector Maps of a distance matrix

Description
Computes the positive Moran’s Eigenvector Maps of a distance matrix.

Usage
mem(
  distance.matrix = NULL,
  distance.threshold = 0,
  colnames.prefix = "mem"
)

Arguments
distance.matrix
  Distance matrix. Default: NULL.
distance.threshold
  Numeric vector with distance thresholds defining different neighborhood extents
  within the distance matrix, Default: 0
colnames.prefix
  Character, name prefix for the output columns. Default: "mem"

Details
Takes the distance matrix x, double-centers it with double_center_distance_matrix(), applies
eigen, and returns eigenvectors with positive normalized eigenvalues (a.k.a Moran’s Eigenvector
Maps, or MEMs). These MEMs are later used as spatial predictors by rf_spatial().

Value
A data frame with positive Moran’s Eigenvector Maps.
See Also

mem_multithreshold(), rf_spatial()

Examples

if(interactive()){

  #loading example distance matrix
data(distance_matrix)

  #Moran's Eigenvector Maps of the distance matrix
  mem <- mem(x = distance_matrix)
}

mem_multithreshold

Moran's Eigenvector Maps for different distance thresholds

Description

Computes Moran's Eigenvector Maps of a distance matrix (using mem()) over different distance thresholds.

Usage

mem_multithreshold(
  distance.matrix = NULL,
  distance.thresholds = NULL,
  max.spatial.predictors = NULL
)

Arguments

distance.matrix
  Distance matrix. Default: NULL.
distance.thresholds
  Numeric vector with distance thresholds defining neighborhood in the distance matrix, Default: NULL.
max.spatial.predictors
  Maximum number of spatial predictors to generate. Only useful to save memory when the distance matrix x is very large. Default: NULL.

Details

The function takes the distance matrix x, computes its weights at difference distance thresholds, double-centers the resulting weight matrices with double_center_distance_matrix(), applies eigen to each double-centered matrix, and returns eigenvectors with positive normalized eigenvalues for different distance thresholds.
Value
A data frame with as many rows as the distance matrix \( x \) containing positive Moran’s Eigenvector Maps. The data frame columns are named "spatial_predic\_DISTANCE\_COLUMN", where DISTANCE is the given distance threshold, and COLUMN is the column index of the given spatial predictor.

Examples
if(interactive()){
    # loading example data
    data(distance_matrix)

    # computing Moran's eigenvector maps for 0, 1000, and 2000 km
    mem.df <- mem_multithreshold(
        distance.matrix = distance_matrix,
        distance.thresholds = c(0, 1000, 2000)
    )
    head(mem.df)
}

moran

Moran's I test

Description
Computes the spatial correlation coefficient (Moran’s I) of a vector given a distance matrix, and a distance threshold used to define “neighborhood”.

Usage
moran(
    x = NULL,
    distance.matrix = NULL,
    distance.threshold = NULL,
    verbose = TRUE
)

Arguments
- **x** Numeric vector, generally model residuals, Default: NULL
- **distance.matrix** Distance matrix among cases in \( x \). The number of rows of this matrix must be equal to the length of \( x \). Default: NULL
- **distance.threshold** numeric value in the range of values available in distance.matrix. Distances below such threshold are set to 0. Default: NULL (which defaults to 0).
- **verbose** Logical, if TRUE, prints a Moran’s I plot. Default: TRUE
Details

Inspired in the Moran.I() function of the ape package.

Value

A list with three named slots:

- test: Data frame with observed and expected Moran’s I values, p-value, and interpretation.
- plot: Moran’s plot of the vector x against the spatial lags of x.
- plot.df: Data used in the Moran’s plot.

See Also

moran_multithreshold()

Examples

if(interactive()){
  #loading example data
  data(distance_matrix)
  data(plant_richness)

  #Moran's I of the response variable
  out <- Moran()
  x = plant_richness$richness_species_vascular,
  distance.matrix = distance_matrix
  )
  out
}

moran_multithreshold  Moran's I test on a numeric vector for different neighborhoods

Description

Applies Moran() to different distance thresholds at the same time.

Usage

moran_multithreshold(
  x = NULL,
  distance.matrix = NULL,
  distance.thresholds = NULL,
  verbose = TRUE
  )
Arguments

- **x**: Numeric vector, generally model residuals. Default: NULL
- **distance.matrix**: Distance matrix among cases in `x`. The number of rows of this matrix must be equal to the length of `x`. Default: NULL
- **distance.thresholds**: Numeric vector, distances below each value are set to 0 on separated copies of the distance matrix for the computation of Moran’s I at different neighborhood distances. If NULL, it defaults to `seq(0, max(distance.matrix)/4, length.out = 2)`. Default: NULL
- **verbose**: Logical, if TRUE, plots Moran’s I values for each distance threshold. Default: TRUE

Details

Using different distance thresholds helps to take into account the uncertainty about what “neighborhood” means in ecological systems (1000km in geological time means little, but 100m might be quite a long distance for a tree to disperse seeds over), and allows to explore spatial autocorrelation of model residuals for several minimum-distance criteria at once.

Value

A named list with the slots:

- **df**: Data frame with the results of `moran` per distance threshold.
- **plot**: A plot of Moran’s I across distance thresholds.
- **max.moran**: Maximum value of Moran’s I across thresholds.
- **max.moran.distance.threshold**: Distance threshold with the maximum Moran’s I value.

See Also

- `moran`

Examples

```r
if(interactive()){
  #loading example data
data(distance_matrix)
data(plant_richness)

  #computing Moran's I for the response variable at several reference distances
  out <- moran_multithreshold(
    x = plant_richness$richness_species_vascular,
    distance.matrix = distance_matrix,
    distance.thresholds = c(0, 100, 1000, 10000),
    plot = TRUE
  )
  out
```
Description

Shows the size of the objects currently in the R environment. Helps to locate large objects cluttering the R environment and/or causing memory problems during the execution of large workflows.

Usage

```
objects_size(n = 10)
```

Arguments

`n` Number of objects to show, Default: 10

Value

A data frame with the row names indicating the object name, the field 'Type' indicating the object type, 'Size' indicating the object size, and the columns 'Length/Rows' and 'Columns' indicating the object dimensions if applicable.

Examples

```
if(interactive()){
  #creating dummy objects
  x <- matrix(runif(100), 10, 10)
  y <- matrix(runif(10000), 100, 100)

  #reading their in-memory size
  objects_size()
}
```
optimization_function

Description
Optimizes the selection of spatial predictors using two different methods: "moran.i", and "p.value".

Usage

```r
optimization_function(
  x = NULL,
  weight.r.squared = NULL,
  weight.penalization.n.predictors = NULL,
  optimization.method = "moran.i"
)
```

Arguments

- **x**: Optimization data frame generated internally by `select.spatial.predictors_sequential()` or `select.spatial.predictors_recursive()`. Default: NULL
- **weight.r.squared**: Numeric between 0 and 1, weight of R-squared in the optimization process. Default: NULL
- **weight.penalization.n.predictors**: Numeric between 0 and 1, weight of the penalization on the number of introduced spatial predictors. Default: NULL
- **optimization.method**: Character, one of "moran.i", and "p.value". Default: "moran.i"

Details
The method "moran.i" tries to maximize \(1 - \text{Moran's I}\) while taking into account the R-squared of the model and a penalization on the number of introduced spatial predictors through the expression

\[(1 - \text{Moran's I}) + w_1 \times \text{r.squared} - w_2 \times \text{penalization}\]

The method "p.value" uses a binary version of the p-values of Moran’s I (1 if >= 0.05, 0 otherwise), and uses the expression

\[\max(1 - \text{Moran's I}, \text{binary p-value}) + w_1 \times \text{r.squared} - w_2 \times \text{penalization}\]

The "moran.i" method generally selects more spatial predictors than the "p.value" method.

Value
A numeric vector with the optimization criteria.

See Also

- `select.spatial.predictors_recursive()`, `select.spatial.predictors_sequential()`
Principal Components Analysis

Description

Extracts all factors of a principal component analysis of a matrix or data frame. Just a convenient wrapper for `prcomp`.

Usage

```r
pca(
  x = NULL,
  colnames.prefix = "pca_factor"
)
```

Arguments

- `x`: numeric matrix or data frame, Default: NULL
- `colnames.prefix`: character, name prefix for the output columns, Default: 'pca_factor'

Details

Columns in `x` with zero variance are removed before computing the PCA.

Value

A data frame with the PCA factors of `x`.

See Also

`pca_multithreshold()`

Examples

```r
if(interactive()){
  # load example distance matrix
data(distance_matrix)

  # PCA of the distance matrix
  out <- pca(x = distance_matrix)
  out
}
```
pca_multithreshold  PCA of a distance matrix over distance thresholds

Description

Computes PCA factors of a distance matrix over different distance thresholds to generate spatial predictors for a model fitted with rf_spatial().

Usage

pca_multithreshold(
  distance.matrix = NULL,
  distance.thresholds = NULL,
  max.spatial.predictors = NULL
)

Arguments

distance.matrix  Distance matrix. Default: NULL
distance.thresholds  Numeric vector with distance thresholds defining neighborhood in the distance matrix, Default: 0
max.spatial.predictors  Integer, maximum number of spatial predictors to generate. Only useful when the distance matrix x is very large. Default: NULL

Details

The distance matrix is converted into weights with weights_from_distance_matrix() before computing the PCA. This produces more meaningful spatial predictors than using the distance matrix as is.

Value

A data frame with the PCA factors of the thresholded matrix. The data frame columns are named "spatial_predictor_DISTANCE_COLUMN", where DISTANCE is the given distance threshold, and COLUMN is the column index of the given predictor.

See Also

pca()
Examples

```r
if(interactive()){

  # loading example distance matrix
  load(distance_matrix)

  # PCA factors of the distance matrix for two reference distances
  x <- pca_multithreshold(
    distance.matrix = distance_matrix,
    distance.thresholds = c(0, 1000)
  )
  head(x)
}
```

---

**plant_richness_df**

*Plant richness and predictors of American ecoregions*

---

**Description**

Richness of vascular plants of the American ecoregions as defined in *Ecoregions 2017*.

**Usage**

```r
data(plant_richness_df)
```

**Format**

A data frame with 227 rows and 22 columns:

- **ecoregion_id**: Id of the ecoregion.
- **x**: Longitude in degrees (WGS84).
- **y**: Latitude in degrees (WGS84).
- **richness_species_vascular**: Number of vascular species found in the ecoregion. Response variable.
- **bias_area_km2**: Area of the ecoregion in squared kilometers.
- **bias_species_per_record**: Number of species divided by the number of spatial GBIF records available in the ecoregion as a measure of sampling bias.
- **climate_aridity_index_average**: Average of the ecoregion.
- **climate_hypervolume**: Volume of the climatic envelope of the ecoregion, computed with the `hypervolume` package.
- **climate_velocity_lgm_average**: Average climate velocity of the ecoregion since the Last Glacial Maximum.
- **neighbors_count**: Number of immediate neighbors of the ecoregion as a measure of connectivity/isolation.
- **neighbors_percent_shared_edge**: Percentage of shared edge with the neighbors as a measure of connectivity/isolation.
- **human_population_density**: Population density of the ecoregion.
- **topography_elevation_average**: Average elevation of the ecoregion.
- **landcover_herbs_percent_average**: Average cover percentage of herbs extracted from MODIS Vegetation Continuous Fields.
- **fragmentation_cohesion**: Geographic fragmentation index of the ecoregion as computed with the R package *landscapemetrics*.
- **fragmentation_division**: Another fragmentation index.
- **neighbors_area**: Total area of the ecoregion's immediate neighbors.
- **human_population**: Human population in the ecoregion.
- **human_footprint_average**: Average human footprint in the ecoregion.
- **climate_bio1_average**: Average mean annual temperature.
- **climate_bio15_minimum**: Average precipitation seasonality.

```r
plot_evaluation(model, 
fill.color = viridis::viridis(3, 
  option = "F", 
  alpha = 0.8, 
  direction = -1),
line.color = "gray30", 
verbose = TRUE, 
notch = TRUE
)
```

**plot_evaluation**  
*Plots the results of a spatial cross-validation*

**Description**

Plots the results of an spatial cross-validation performed with `rf_evaluate()`.

**Usage**

```r
plot_evaluation(
  model,
  fill.color = viridis::viridis(3, 
    option = "F", 
    alpha = 0.8, 
    direction = -1),
  line.color = "gray30", 
  verbose = TRUE, 
  notch = TRUE
)
```
Arguments

model A model resulting from `rf_evaluate()`.
fill.color Character vector with three hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(3)`). Default: `viridis::viridis(3, option = "F", alpha = 0.8, direction = -1)`
line.color Character string, color of the line produced by `ggplot2::geom_smooth()`. Default: "gray30"
verbose Logical, if TRUE the plot is printed. Default: TRUE
notch Logical, if TRUE, boxplot notches are plotted. Default: TRUE

Value

A ggplot.

See Also

`rf_evaluate()`, `get_evaluation()`, `print_evaluation()`.

Examples

```r
if(interactive()){

#loading example data
data(plant_richness_df)
data(distance_matrix)

#fitting a random forest model
rf.model <- rf(
  data = plant_richness_df,
  dependent.variable.name = "richness_species_vascular",
  predictor.variable.names = colnames(plant_richness_df)[5:21],
  distance.matrix = distance_matrix,
  distance.thresholds = 0,
  n.cores = 1,
  verbose = FALSE
)

#evaluating the model with spatial cross-validation
rf.model <- rf_evaluate(
  model = rf.model,
  xy = plant_richness_df[, c("x", "y")],
  n.cores = 1
)

#plotting the evaluation results
plot_evaluation(rf.model)
}
```
plot_importance

Plots the variable importance of a model

Description

Plots variable importance scores of `rf()`, `rf_repeat()`, and `rf_spatial()` models. Distributions of importance scores produced with `rf_repeat()` are plotted using `ggplot2::geom_violin`, which shows the median of the density estimate rather than the actual median of the data. However, the violin plots are ordered from top to bottom by the real median of the data to make small differences in median importance easier to spot. This function does not plot the result of `rf_importance()` yet, but you can find it under `model$importance$cv.per.variable.plot`.

Usage

```r
plot_importance(
  model,
  fill.color = viridis::viridis(
    100,
    option = "F",
    direction = -1,
    alpha = 1,
    end = 0.9
  ),
  line.color = "white",
  verbose = TRUE
)
```

Arguments

- `model`: A model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`, or a data frame with variable importance scores (only for internal use within the package functions).
- `fill.color`: Character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F", direction = -1, alpha = 0.8, end = 0.9)`
- `line.color`: Character string, color of the line produced by `ggplot2::geom_smooth()`. Default: "white"
- `verbose`: Logical, if TRUE, the plot is printed. Default: TRUE

Value

A `ggplot`.

See Also

`print_importance()`, `get_importance()`
Examples

if(interactive()){

  #loading example data
  data(plant_richness_df)
  data(distance_matrix)

  #fitting a random forest model
  rf.model <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = 0,
    n.cores = 1,
    verbose = FALSE
  )

  #plotting variable importance scores
  plot.importance(model = rf.model)
}

plot_moran

Plots a Moran’s I test of model residuals

Description

Plots the results of spatial autocorrelation tests for a variety of functions within the package. The x axis represents the Moran’s I estimate, the y axis contains the values of the distance thresholds, the dot sizes represent the p-values of the Moran’s I estimate, and the red dashed line represents the theoretical null value of the Moran’s I estimate.

Usage

plot_moran(
  model,
  point.color = viridis::viridis(100,
    option = "F",
    direction = -1
  ),
  line.color = "gray30",
  option = 1,
  ncol = 1,
  verbose = TRUE
)
Arguments

model A model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`, or a data frame generated by `moran()`. Default: NULL

point.color Colors of the plotted points. Can be a single color name (e.g. "red4"), a character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F")`

line.color Character string, color of the line produced by `ggplot2::geom_smooth()`. Default: "gray30"

option Integer, type of plot. If 1 (default) a line plot with Moran’s I and p-values across distance thresholds is returned. If 2, scatterplots of residuals versus lagged residuals per distance threshold and their corresponding slopes are returned. In models fitted with `rf_repeat()`, the residuals and lags of the residuals are computed from the median residuals across repetitions. Option 2 is disabled if x is a data frame generated by `moran()`.

ncol Number of columns of the plot. Only relevant when option = 2. Argument `ncol` of `wrap_plots`.

verbose Logical, if TRUE, the resulting plot is printed. Default: TRUE

Value

A ggplot.

See Also

`moran()`, `moran_multithreshold()`

Examples

```r
if(interactive()){

  # loading example data
data(plant_richness_df)
data(distance.matrix)

  # fitting a random forest model
rf.model <- rf(
  data = plant_richness_df,
dependent.variable.name = "richness_species_vascular",
predictor.variable.names = colnames(plant_richness_df)[5:21],
distance.matrix = distance_matrix,
distance.thresholds = c(0, 1000, 2000),
cores = 1,
verbose = FALSE
)

  # Incremental/multiscale Moran’s I
plot_moran(rf.model)
}
```
plot_optimization

# Moran's scatterplot
plot_moran(rf.model, option = 2)
}

plot_optimization  Optimization plot of a selection of spatial predictors

Description

Plots optimization data frames produced by `select.spatial.predictors_sequential()` and `select.spatial.predictors_recursive()`.

Usage

```r
plot_optimization(
  model,
  point.color = viridis::viridis(100, option = "F", direction = -1),
  verbose = TRUE
)
```

Arguments

- `model` A model produced by `rf.spatial()`, or an optimization data frame produced by `select.spatial.predictors_sequential()` or `select.spatial.predictors_recursive()`.
- `point.color` Colors of the plotted points. Can be a single color name (e.g. "red4"), a character vector with hexadecimal codes (e.g. 
  "#440154FF" 
  "#21908CFF" 
  "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F", direction = -1)`
- `verbose` Logical, if TRUE the plot is printed. Default: TRUE

Details

If the method used to fit a model with `rf.spatial()` is "hengl", the function returns nothing, as this method does not require optimization.

Value

A ggplot.
Examples

```r
if(interactive()){
  #loading example data
data(distance_matrix)
data(plant_richness_df)

  #names of the response and predictors
  dependent.variable.name <- "richness_species_vascular"
predictor.variable.names <- colnames(plant_richness_df)[5:21]

  #spatial model
  model <- rf_spatial(
    data = plant_richness_df,
    dependent.variable.name = dependent.variable.name,
    predictor.variable.names = predictor.variable.names,
    distance.matrix = distance_matrix,
    distance.thresholds = 0,
    method = "mem.moran.sequential",
    n.cores = 1,
    seed = 1
  )

  #plotting selection of spatial predictors
  plot_optimization(model = model)
}
```

plot_residuals_diagnostics

*Plot residuals diagnostics*

Description

Plots normality and autocorrelation tests of model residuals.

Usage

```r
plot_residuals_diagnostics(
  model,  # model object
  point.color = viridis::viridis(100, option = "F"),  # point color
  line.color = "gray10",  # line color
  fill.color = viridis::viridis(4, option = "F", alpha = 0.95)[2],  # fill color
  option = 1,  # plot option
  ncol = 1,  # number of columns
  verbose = TRUE  # verbose output
)
```
Arguments

- **model**: A model produced by `rf()`, `rf_repeat()`, or `rf_spatial()`.
- **point.color**: Colors of the plotted points. Can be a single color name (e.g. "red4"), a character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F")`
- **line.color**: Character string, color of the line produced by `ggplot2::geom_smooth()`. Default: "gray30"
- **fill.color**: Character string, fill color of the bars produced by `ggplot2::geom_histogram()`. Default: `viridis::viridis(4, option = "F", alpha = 0.95 )[2]`
- **option**: (argument of `plot_moran()`) Integer, type of plot. If 1 (default) a line plot with Moran’s I and p-values across distance thresholds is returned. If 2, scatterplots of residuals versus lagged residuals per distance threshold and their corresponding slopes are returned. In models fitted with `rf_repeat()`, the residuals and lags of the residuals are computed from the median residuals across repetitions. Option 2 is disabled if x is a data frame generated by `moran()`.
- **ncol**: (argument of `plot_moran()`) Number of columns of the Moran’s I plot if option = 2.
- **verbose**: Logical, if TRUE, the resulting plot is printed. Default: TRUE

Value

A patchwork object.

Examples

```r
if(interactive()){

  # load example data
data(plant_richness_df)
data(distance_matrix)

  # fit a random forest model
  x <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    n.cores = 1
  )

  # residuals diagnostics
  plot_residuals_diagnostics(x)
}
```
plot_response_curves  
Plots the response curves of a model.

Description
Plots the response curves of models fitted with rf(), rf_repeat(), or rf.spatial().

Usage
plot_response_curves(
  model = NULL,
  variables = NULL,
  quantiles = c(0.1, 0.5, 0.9),
  grid.resolution = 200,
  line.color = viridis::viridis(length(quantiles), option = "F", end = 0.9),
  ncol = 2,
  show.data = FALSE,
  verbose = TRUE
)

Arguments
model  A model fitted with rf(), rf_repeat(), or rf.spatial().
variables  Character vector, names of predictors to plot. If NULL, the most important variables (importance higher than the median) in x are selected. Default: NULL.
quantiles  Numeric vector with values between 0 and 1, argument probs of quantile. Quantiles to set the other variables to. Default: c(0.1, 0.5, 0.9)
grid.resolution  Integer between 20 and 500. Resolution of the plotted curve Default: 100
line.color  Character vector with colors, or function to generate colors for the lines representing quantiles. Must have the same number of colors as quantiles are defined. Default: viridis::viridis(length(quantiles), option = "F", end = 0.9)
ncol  Integer, argument of wrap_plots. Defaults to the rounded squared root of the number of plots. Default: 2
show.data  Logical, if TRUE, the observed data is plotted along with the response curves. Default: FALSE
verbose  Logical, if TRUE the plot is printed. Default: TRUE

Details
All variables that are not plotted in a particular response curve are set to the values of their respective quantiles, and the response curve for each one of these quantiles is shown in the plot. When the input model was fitted with rf_repeat() with keep.models = TRUE, then the plot shows the median of all model runs, and each model run separately as a thinner line. The output list can be plotted all at once with patchwork::wrap_plots(p) or cowplot::plot_grid(plotlist = p), or one by one by extracting each plot from the list.
plot_response_surface

Plots the response surfaces of a random forest model

Value
A list with slots named after the selected variables, with one ggplot each.

See Also
plot_response_surface()

Examples
if(interactive()){
  #loading example data
data(plant_richness_df)

  #fitting a random forest model
  m <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    n.cores = 1,
    verbose = FALSE
  )

  #response curves of most important predictors
  plot_response_curves(model = m)
}

plot_response_surface

Plots response surfaces for any given pair of predictors in a rf(), rf_repeat(), or rf_spatial() model.

Usage
plot_response_surface(
  model = NULL,
a = NULL,
b = NULL,
quantiles = 0.5,
grid.resolution = 100,
point.size.range = c(0.5, 2.5),
point.alpha = 1,
fill.color = viridis::viridis(100, option = "F", direction = -1, alpha = 0.9),
point.color = "gray30",
verbose = TRUE
)
Arguments

- **model**: A model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`. Default NULL
- **a**: Character string, name of a model predictor. If NULL, the most important variable in model is selected. Default: NULL
- **b**: Character string, name of a model predictor. If NULL, the second most important variable in model is selected. Default: NULL
- **quantiles**: Numeric vector between 0 and 1. Argument `probs` of the function `quantile`. Quantiles to set the other variables to. Default: 0.5
- **grid.resolution**: Integer between 20 and 500. Resolution of the plotted surface. Default: 100
- **point.size.range**: Numeric vector of length 2 with the range of point sizes used by `geom_point`. Using `c(-1, -1)` removes the points. Default: `c(0.5, 2.5)`
- **point.alpha**: Numeric between 0 and 1, transparency of the points. Setting it to 0 removes all points. Default: 1.
- **fill.color**: Character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F", direction = -1, alpha = 0.9)`
- **point.color**: Character vector with a color name (e.g. "red4"). Default: gray30
- **verbose**: Logical, if TRUE the plot is printed. Default: TRUE

Details

All variables that are not `a` or `b` in a response curve are set to the values of their respective quantiles to plot the response surfaces. The output list can be plotted all at once with `patchwork::wrap_plots(p)` or `cowplot::plot_grid(plotlist = p)`, or one by one by extracting each plot from the list.

Value

A list with slots named after the selected quantiles, each one with a ggplot.

See Also

- `plot_response_curves()`

Examples

```r
if(interactive()){

  #load example data
data(plant_richness_df)

  #fit random forest model
out <- rf(
    data = plant_richness_df,
dependent.variable.name = "richness_species_vascular",
predictor.variable.names = colnames(plant_richness_df)[5:21],
```
n.cores = 1,
verbose = FALSE
)

# plot interactions between most important predictors
plot_response_surfaces(x = out)

plot_training_df

---

**plot_training_df**  
*Scatterplots of a training data frame*

**Description**

Plots the dependent variable against each predictor.

**Usage**

```r
plot_training_df(
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
  ncol = 4,
  method = "loess",
  point.color = viridis::viridis(100, option = "F"),
  line.color = "gray30"
)
```

**Arguments**

- `data`  
  Data frame with a response variable and a set of predictors. Default: NULL
- `dependent.variable.name`  
  Character string with the name of the response variable. Must be in the column names of `data`. If the dependent variable is binary with values 1 and 0, the argument `case.weights` of `ranger` is populated by the function `case_weights()`. Default: NULL
- `predictor.variable.names`  
  Character vector with the names of the predictive variables. Every element of this vector must be in the column names of `data`. Optionally, the result of `auto_cor()` or `auto_vif()`. Default: NULL
- `ncol`  
  Number of columns of the plot. Argument `ncol` of `wrap_plots`. Default: NULL
- `method`  
  Method for `geom_smooth`, one of: "lm", "glm", "gam", "loess", or a function, for example `mgcv::gam`. Default: 'loess'
- `point.color`  
  Colors of the plotted points. Can be a single color name (e.g. "red4"), a character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F")`
plot_training_df_moran

line.color  Character string, color of the line produced by ggplot2::geom_smooth(). Default: "gray30"

Value
A wrap_plots object.

Examples
if(interactive()){

  #load example data
data(plant_richness_df)

  #scatterplot of the training data
plot_training_data(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21]
  )
}

plot_training_df_moran

Moran’s I plots of a training data frame

Description
Plots the the Moran’s I test of the response and the predictors in a training data frame.

Usage
plot_training_df_moran(
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
  distance.matrix = NULL,
  distance.thresholds = NULL,
  fill.color = viridis::viridis(100, option = "F", direction = -1),
  point.color = "gray30"
)

Arguments
  data        Data frame with a response variable and a set of predictors. Default: NULL
dependent.variable.name

Character string with the name of the response variable. Must be in the column names of data. If the dependent variable is binary with values 1 and 0, the argument case.weights of ranger is populated by the function case_weights(). Default: NULL

predictor.variable.names

Character vector with the names of the predictive variables. Every element of this vector must be in the column names of data. Optionally, the result of auto_cor() or auto_vif() Default: NULL

distance.matrix

Squared matrix with the distances among the records in data. The number of rows of distance.matrix and data must be the same. If not provided, the computation of the Moran's I of the residuals is omitted. Default: NULL

distance.thresholds

Numeric vector, distances below each value are set to 0 on separated copies of the distance matrix for the computation of Moran's I at different neighborhood distances. If NULL, it defaults to seq(0, max(distance.matrix)/4, length.out = 2). Default: NULL

fill.color

Character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. viridis::viridis(100)). Default: viridis::viridis(100, option = "F", direction = -1)

point.color

Character vector with a color name (e.g. "red4"). Default: gray30

Value

A ggplot2 object.

Examples

if(interactive()){

  #load example data
  data(plant_richness_df)
  data(distance_matrix)

  #plot Moran's I of training data
  plot_moran_training_data(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = c(0, 2000, 4000, 6000, 8000)
  )
}

plot_tuning

Plots a tuning object produced by rf_tuning()

Description

Plots the tuning of the hyperparameters `num.trees`, `mtry`, and `min.node.size` performed by `rf_tuning()`.

Usage

plot_tuning(
  model,
  point.color = viridis::viridis(100, option = "F"),
  verbose = TRUE
)

Arguments

- **model**: A model fitted with `rf_tuning()`. Default: NULL
- **point.color**: Colors of the plotted points. Can be a single color name (e.g. "red4"), a character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F")`
- **verbose**: Logical, if TRUE, the plot is printed. Default: TRUE

Value

A ggplot.

See Also

`rf_tuning()`

Examples

```r
if(interactive()){

  # load example data
  data(plant_richness_df)

  # fit random forest model
  rf.model <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
```
prepare_importance_spatial

Prepares variable importance objects for spatial models

Description

Prepares variable importance data frames and plots for models fitted with `rf_spatial()`.

Usage

prepare_importance_spatial(model)

Arguments

model An importance data frame with spatial predictors, or a model fitted with `rf_spatial()`.

Value

A list with importance data frames in different formats depending on whether the model was fitted with `rf()` or `rf_repeat()`.

Examples

if(interactive()){
  #loading example data
  data(distance_matrix)
  data(plant_richness_df)

  #fittind spatial model
  model <- rf_spatial(
    distance.matrix = distance_matrix,
    distance.thresholds = 0,
    n.cores = 1,
    verbose = FALSE
  )

  #tune random forest model
  rf.model <- rf_tuning(
    model = rf.model,
    xy = plant_richness_df[, c("x", "y")],
    n.cores = 1,
    verbose = FALSE
  )

  #generate tuning plot
  plot_tuning(model = rf.model)
}
print.rf

```r
data = plant_richness_df, 
dependent.variable.name = "richness_species_vascular", 
predictor.variable.names = colnames(plant_richness_df)[5:21], 
distance.matrix = distance_matrix, 
distance.thresholds = 0, 
n.cores = 1
)

# preparing the importance data frame 
importance <- prepare_importance_spatial(model) 
names(importance)
```

---

**print.rf**

*Custom print method for random forest models*

**Description**

Custom print method for models fitted with `rf()`, `rf_repeat()`, and `rf_spatial()`.

**Usage**

```r
## S3 method for class 'rf'
print(x, ...)
```

**Arguments**

- `x` A model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`.
- `...` Additional arguments for print methods.

**Value**

Prints model details to the console.

**See Also**

- `print_evaluation()`, `print_importance()`, `print_moran()`, `print_performance()`

**Examples**

```r
if(interactive()){ 
  # loading example data
  data("plant_richness_df")
  data("distance_matrix")

  # fitting random forest model
  rf.model <- rf(
```
data = plant_richness_df,  
dependent.variable.name = "richness_species_vascular",  
predictor.variable.names = colnames(plant_richness_df)[5:21],  
distance.matrix = distance_matrix,  
distance.thresholds = 0,  
n.cores = 1  
)  

# printing model summary  
print(rf.model)  
}  

print_evaluation  

Description  
Prints cross-validation results

Usage  
print_evaluation(model)

Arguments  
model A model resulting from rf_evaluate().

Value  
A table printed to the standard output.

See Also  
plot_evaluation(), get_evaluation()

Examples  
if(interactive()){
  
  # loading example data  
data(plant_richness_df)  
data(distance_matrix)

  # fitting random forest model  
rf.model <- rf(  
data = plant_richness_df,  
dependent.variable.name = "richness_species_vascular",  
predictor.variable.names = colnames(plant_richness_df)[5:21],  
distance.matrix = distance_matrix,  
distance.thresholds = 0,  
n.cores = 1  
)  
  
  # printing model summary  
  print(rf.model)  
}
print_importance

    n.cores = 1,
    verbose = FALSE
  )

#evaluation with spatial cross-validation
rf.model <- rf_evaluate(
  model = rf.model,
  xy = plant_richness_df[, c("x", "y")],
  n.cores = 1
)

#checking evaluation results
print_evaluation(rf.model)

print_importance

Prints variable importance

Description
Prints variable importance scores from rf, rf_repeat, and rf_spatial models.

Usage
print_importance(
  model,
  verbose = TRUE
)

Arguments
model A model fitted with rf, rf_repeat, or rf_spatial.
verbose Logical, if TRUE, variable importance is returned. Default: TRUE

Value
A table printed to the standard output.

See Also
plot_importance(), get_importance()
Examples

if(interactive()){

  #loading example data
data(plant_richness_df)
data(distance.matrix)

  #fitting a random forest model
  rf.model <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = 0,
    n.cores = 1,
    verbose = FALSE
  )

  #printing variable importance scores
  print_importance(model = rf.model)
}

print_moran

Prints results of a Moran’s I test

Description

Prints the results of a Moran’s I test on the residuals of a model.

Usage

print_moran(
  model,
  caption = NULL,
  verbose = TRUE
)

Arguments

model A model fitted with rf(), rf_repeat(), or rf_spatial().
caption Character, caption of the output table, Default: NULL
verbose Logical, if TRUE, the resulting table is printed into the console, Default: TRUE

Value

Prints a table in the console using the huxtable package.
### Description

Prints the performance slot of a model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`. For models fitted with `rf_repeat()` it shows the median and the median absolute deviation of each performance measure.

### Usage

```r
print_performance(model)
```

### Arguments

- **model**  
  Model fitted with `rf()`, `rf_repeat()`, or `rf_spatial()`.

### Value

Prints model performance scores to the console.
See Also

`print_performance()`, `get_performance()`

Examples

```r
if(interactive()){

  # loading example data
  data(plant_richness_df)
  data(distance.matrix)

  # fitting a random forest model
  rf.model <- rf(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    distance.matrix = distance_matrix,
    distance.thresholds = 0,
    n.cores = 1,
    verbose = FALSE
  )

  # printing performance scores
  print_performance(rf.model)
}
```

---

**Rank_spatial_predictors**

*Ranks spatial predictors*

**Description**

Ranks spatial predictors generated by `mem_multithreshold()` or `pca_multithreshold()` by their effect in reducing the Moran’s I of the model residuals (`ranking.method = "effect"`), or by their own Moran’s I (`ranking.method = "moran"`).

In the former case, one model of the type `y ~ predictors + spatial_predictor_X` is fitted per spatial predictor, and the Moran’s I of this model’s residuals is compared with the one of the model without spatial predictors (`y ~ predictors`), to finally rank the spatial predictor from maximum to minimum difference in Moran’s I.

In the latter case, the spatial predictors are ordered by their Moran’s I alone (this is the faster option).

In both cases, spatial predictors that are redundant with others at a Pearson correlation > 0.5 and spatial predictors with no effect (no reduction of Moran’s I or Moran’s I of the spatial predictor equal or lower than 0) are removed.

This function has been designed to be used internally by `rf_spatial()` rather than directly by a user.
rank_spatial_predictors

Usage

rank_spatial_predictors(
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
  distance.matrix = NULL,
  distance.thresholds = NULL,
  ranger.arguments = NULL,
  spatial.predictors.df = NULL,
  ranking.method = c("moran", "effect"),
  reference.moran.i = 1,
  verbose = FALSE,
  n.cores = parallel::detectCores() - 1,
  cluster = NULL
)

Arguments

data Data frame with a response variable and a set of predictors. Default: NULL

dependent.variable.name Character string with the name of the response variable. Must be in the column names of data. Default: NULL

predictor.variable.names Character vector with the names of the predictive variables. Every element of this vector must be in the column names of data. Default: NULL

distance.matrix Squared matrix with the distances among the records in data. The number of rows of distance.matrix and data must be the same. If not provided, the computation of the Moran’s I of the residuals is omitted. Default: NULL

distance.thresholds Numeric vector with neighborhood distances. All distances in the distance matrix below each value in distance.thresholds are set to 0 for the computation of Moran’s I. If NULL, it defaults to seq(0, max(distance.matrix), length.out = 4). Default: NULL

ranger.arguments List with ranger arguments. See rf or rf_repeat for further details.

spatial.predictors.df Data frame of spatial predictors.

ranking.method Character, method used by to rank spatial predictors. The method “effect” ranks spatial predictors according how much each predictor reduces Moran’s I of the model residuals, while the method “moran” ranks them by their own Moran’s I. Default: “moran”.

reference.moran.i Moran’s I of the residuals of the model without spatial predictors. Default: 1

verbose Logical, if TRUE, messages and plots generated during the execution of the function are displayed. Default: TRUE
**n.cores**  
Integer, number of cores to use for parallel execution. Creates a socket cluster with `parallel::makeCluster()`, runs operations in parallel with `foreach` and `%dopar%`, and stops the cluster with `parallel::clusterStop()` when the job is done. Default: `parallel::detectCores() - 1`

**cluster**  
A cluster definition generated with `parallel::makeCluster()`. If provided, overrides `n.cores`. When `cluster = NULL` (default value), and `model` is provided, the cluster in `model`, if any, is used instead. If this cluster is `NULL`, then the function uses `n.cores` instead. The function does not stop a provided cluster, so it should be stopped with `parallel::stopCluster()` afterwards. The cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the `model` argument, or using the `%>%` pipe. Default: `NULL`

**Value**
A list with four slots:

- **method**: Character, name of the method used to rank the spatial predictors.
- **criteria**: Data frame with two different configurations depending on the ranking method. If `ranking.method = "effect"`, the columns contain the names of the spatial predictors, the r-squared of the model, the Moran’s I of the model residuals, the difference between the Moran’s I of the model including the given spatial predictor, and the Moran’s I of the model fitted without spatial predictors, and the interpretation of the Moran’s I value. If `ranking.method = "moran"`, only the name of the spatial predictor and it’s Moran’s I are in the output data frame.
- **ranking**: Ordered character vector with the names of the spatial predictors selected.
- **spatial.predictors.df**: data frame with the selected spatial predictors in the order of the ranking.

**Examples**

```r
if(interactive()){  
  #loading distance matrix  
data(distance_matrix)  

  #computing Moran's Eigenvector Maps  
  mem.df <- mem(  
    distance.matrix = distance_matrix[,1:50],  
    distance.threshold = 0  
  )  

  #ranking by the Moran's I of the spatial predictor  
  rank <- rank_spatial_predictors(  
    distance.matrix = distance_matrix[,1:50],  
    distance.thresholds = 0,  
    spatial.predictors.df = mem.df,  
    ranking.method = "moran",  
    n.cores = 1  
  )
}
```
# checking Moran's I of MEMs
rank$criteria

# checking rank of MEMs
rank$ranking
}

rescale_vector

Rescales a numeric vector into a new range

Description
Rescales a numeric vector to a new range.

Usage
rescale_vector(
  x = NULL,
  new.min = 0,
  new.max = 1,
  integer = FALSE
)

Arguments
x Numeric vector. Default: NULL
new.min New minimum value. Default: 0
new.max New maximum value. Default: 1
integer Logical, if TRUE, coerces the output to integer. Default: FALSE

Value
A numeric vector of the same length as x, but with its values rescaled between new.min and new.max.

Examples
if(interactive()){
  out <- rescale_vector(
    x = rnorm(100),
    new.min = 0,
    new.max = 100,
    integer = TRUE
  )
  out
}

residuals_diagnostics  Normality test of a numeric vector

Description
Applies a Shapiro-Wilks test to a numeric vector, and plots the qq plot and the histogram.

Usage
residuals_diagnostics(residuals, predictions)

Arguments
residuals Numeric vector, model residuals.
predictions Numeric vector, model predictions.

Details
The function shapiro.test() has a hard limit of 5000 cases. If the model residuals have more than 5000 cases, then sample(x = residuals, size = 5000) is applied to the model residuals before the test.

Value
A list with four slots:
- `w` W statistic returned by shapiro.test().
- `p.value` p-value of the Shapiro test.
- `interpretation` Character vector, one of "x is normal", "x is not normal".
- `plot` A patchwork plot with the qq plot and the histogram of x.

See Also
ggplot, aes, geom_qq_line, ggtheme, labs, geom_freqpoly, geom_abline, plot_annotation

Examples
if(interactive()){
  residuals_diagnostics(
    residuals = runif(100),
    predictions = runif(100)
  )
}
}
residuals_test

Normality test of a numeric vector

Description

Applies a Shapiro-Wilks test to a numeric vector, and returns a list with the statistic W, its p-value, and a character string with the interpretation.

Usage

residuals_test(residuals)

Arguments

residuals Numeric vector, model residuals.

Value

A list with four slots:

- w W statistic returned by shapiro.test()
- p.value p-value of the Shapiro test
- interpretation Character vector, one of "x is normal", "x is not normal"
- plot A patchwork plot with the qq plot and the histogram of x.

See Also

ggplot,aes.geom_qq_line.ggtheme,labs,geom_freqpoly,geom_abline plot_annotation

Examples

if(interactive()){

  residuals_test(residuals = runif(100))
}

rf

Random forest models with Moran's I test of the residuals

Description

A convenient wrapper for ranger that completes its output by providing the Moran’s I of the residuals for different distance thresholds, the rmse and nrmse (as computed by root_mean_squared_error()), and variable importance scores based on a scaled version of the data generated by scale.
Usage

```r
rf(
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
  distance.matrix = NULL,
  distance.thresholds = NULL,
  xy = NULL,
  ranger.arguments = NULL,
  scaled.importance = FALSE,
  seed = 1,
  verbose = TRUE,
  n.cores = parallel::detectCores() - 1,
  cluster = NULL
)
```

Arguments

data
  Data frame with a response variable and a set of predictors. Default: NULL

dependent.variable.name
  Character string with the name of the response variable. Must be in the column names of `data`. If the dependent variable is binary with values 1 and 0, the argument `case.weights` of `ranger` is populated by the function `case_weights()`. Default: NULL

predictor.variable.names
  Character vector with the names of the predictive variables. Every element of this vector must be in the column names of `data`. Optionally, the result of `auto_cor()` or `auto_vif()`. Default: NULL

distance.matrix
  Squared matrix with the distances among the records in `data`. The number of rows of `distance.matrix` and `data` must be the same. If not provided, the computation of the Moran's I of the residuals is omitted. Default: NULL

distance.thresholds
  Numeric vector with neighborhood distances. All distances in the distance matrix below each value in `distance.thresholds` are set to 0 for the computation of Moran's I. If `NULL`, it defaults to `seq(0, max(distance.matrix), length.out = 4)`. Default: NULL

xy
  (optional) Data frame or matrix with two columns containing coordinates and named "x" and "y". It is not used by this function, but it is stored in the slot `ranger.arguments$xy` of the model, so it can be used by `rf_evaluate()` and `rf_tuning()`. Default: NULL

ranger.arguments
  Named list with `ranger` arguments (other arguments of this function can also go here). All `ranger` arguments are set to their default values except for 'importance', that is set to 'permutation' rather than 'none'. The `ranger` arguments x, y, and formula are disabled. Please, consult the help file of `ranger` if you are not familiar with the arguments of this function.
rf

scaled.importance Logical, if TRUE, the function scales data with scale and fits a new model to compute scaled variable importance scores. This makes variable importance scores of different models somewhat comparable. Default: FALSE

seed Integer, random seed to facilitate reproducibility. If set to a given number, the returned model is always the same. Default: 1

verbose Boolean. If TRUE, messages and plots generated during the execution of the function are displayed. Default: TRUE

n.cores Integer, number of cores to use. Default: parallel::detectCores() - 1

cluster A cluster definition generated with parallel::makeCluster(). This function does not use the cluster, but can pass it on to other functions when using the %>% pipe. It will be stored in the slot cluster of the output list. Default: NULL

Details

Please read the help file of ranger for further details. Notice that the formula interface of ranger is supported through ranger.arguments, but variable interactions are not allowed (but check the_feature_engineer()).

Value

A ranger model with several extra slots:

- ranger.arguments: Stores the values of the arguments used to fit the ranger model.
- importance: A list containing a data frame with the predictors ordered by their importance, a ggplot showing the importance values, and local importance scores (difference in accuracy between permuted and non permuted variables for every case, computed on the out-of-bag data).
- performance: performance scores: R squared on out-of-bag data, R squared (cor(observed, predicted)^2), pseudo R squared (cor(observed, predicted)), RMSE, and normalized RMSE (NRMSE).
- residuals: residuals, normality test of the residuals computed with residuals_test(), and spatial autocorrelation of the residuals computed with moran_multithreshold().

Examples

if(interactive()){

#loading example data
data("plant_richness_df")
data("distance_matrix")

#fitting random forest model
out <- rf(
  data = plant_richness_df,

  predictor.variable.names = colnames(plant_richness_df)[8:21],
  distance.matrix = distance_matrix,
  distance.thresholds = c(0, 1000)
)

# fitting model with these ranger arguments
out <- rf(
  ranger.arguments = my.ranger.arguments,
  n.cores = 1
)

}
Description

Uses `rf_evaluate()` to compare the performance of several models on independent spatial folds via spatial cross-validation.

Usage

```r
rf_compare(
  models = NULL,
  xy = NULL,
  repetitions = 30,
  training.fraction = 0.75,
  metrics = c("r.squared", "pseudo.r.squared", "rmse", "nrmse", "auc"),
  distance.step = NULL,
  distance.step.x = NULL,
  distance.step.y = NULL,
  fill.color = viridis::viridis(100, option = "F", direction = -1, alpha = 0.8),
  line.color = "gray30",
  seed = 1,
  verbose = TRUE,
  n.cores = parallel::detectCores() - 1,
  cluster = NULL
)
```

Arguments

- **models**
  Named list with models resulting from `rf()`, `rf.spatial()`, `rf.tuning()`, or `rf_evaluate()`. Example: `models = list(a = model.a, b = model.b)`. Default: `NULL`

- **xy**
  Data frame or matrix with two columns containing coordinates and named "x" and "y". Default: `NULL`

- **repetitions**
  Integer, number of spatial folds to use during cross-validation. Must be lower than the total number of rows available in the model’s data. Default: `30`

- **training.fraction**
  Proportion between 0.5 and 0.9 indicating the proportion of records to be used as training set during spatial cross-validation. Default: `0.75`

- **metrics**
  Character vector, names of the performance metrics selected. The possible values are: "r.squared" (cor(obs, pred) ^ 2), "pseudo.r.squared" (cor(obs, pred),"rmse"(sqrt(sum((obs - pred)^2)/length(obs))),"nrmse"(rmse/(quantile(obs, 0.75) - quantile(obs, 0.25))). Default: c("r.squared", "pseudo.r.squared", "rmse", "nrmse")

- **distance.step**
  Numeric, argument `distance.step` of `thinning_til_n()`. distance step used during the selection of the centers of the training folds. These fold centers are selected by thinning the data until a number of folds equal or lower than `repetitions` is reached. Its default value is 1/1000th the maximum distance within records in `xy`. Reduce it if the number of training folds is lower than expected.
distance.step.x

Numeric, argument distance.step.x of `make_spatial_folds()`. Distance step used during the growth in the x axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the x coordinates).

distance.step.y

Numeric, argument distance.step.x of `make_spatial_folds()`. Distance step used during the growth in the y axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the y coordinates).

fill.color

Character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F", direction = -1)`

line.color

Character string, color of the line produced by `ggplot2::geom_smooth()`. Default: "gray30"

seed

Integer, random seed to facilitate reproducibility. If set to a given number, the results of the function are always the same. Default: 1.

verbose

Logical. If TRUE, messages and plots generated during the execution of the function are displayed. Default: TRUE.

n.cores

Integer, number of cores to use for parallel execution. Creates a socket cluster with `parallel::makeCluster()`, runs operations in parallel with `foreach` and `%dopar%`, and stops the cluster with `parallel::clusterStop()` when the job is done. Default: `parallel::detectCores() - 1`

cluster

A cluster definition generated with `parallel::makeCluster()`. If provided, overrides `n.cores`. When `cluster = NULL` (default value), and `model` is provided, the cluster in `model`, if any, is used instead. If this cluster is NULL, then the function uses `n.cores` instead. The function does not stop a provided cluster, so it should be stopped with `parallel::stopCluster()` afterwards. The cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the `model` argument, or using the `%>%` pipe. Default: NULL

Value

A list with three slots:

- `comparison.df`: Data frame with one performance value per spatial fold, metric, and model.
- `spatial.folds`: List with the indices of the training and testing records for each evaluation repetition.
- `plot`: Violin-plot of `comparison.df`.

See Also

`rf_evaluate()`

Examples

```r
if(interactive()){
```
### Description
Evaluates the performance of random forest on unseen data over independent spatial folds.

### Usage
```r
define a spatial model with Moran's Eigenvector Maps
rf.spatial <- rf.spatial(
    model = rf.model,
    n.cores = 1
)

#comparing the spatial and non spatial models
comparison <- rf_compare(
    models = list("Non spatial" = rf.model,
                  "Spatial" = rf.spatial
    ),
    xy = plant_richness_df[, c("x", "y")],
    metrics = c("r.squared", "rmse"),
    n.cores = 1
)
```

---

`rf_evaluate` **Evaluates random forest models with spatial cross-validation**

```r
rf_evaluate(model = NULL,
            xy = NULL,
            repetitions = 30,
            training.fraction = 0.75,
            metrics = c("r.squared", "pseudo.r.squared", "rmse", "nrmse", "auc"),
            distance.step = NULL,
            distance.step.x = NULL,
```
distance.step.y = NULL,
grow.testing.folds = FALSE,
seed = 1,
verbose = TRUE,
n.cores = parallel::detectCores() - 1,
cluster = NULL
)

Arguments
model Model fitted with rf(), rf_repeat(), or rf_spatial().
xy Data frame or matrix with two columns containing coordinates and named "x" and "y". If NULL, the function will throw an error. Default: NULL
repetitions Integer, number of spatial folds to use during cross-validation. Must be lower than the total number of rows available in the model's data. Default: 30
training.fraction Proportion between 0.5 and 0.9 indicating the proportion of records to be used as training set during spatial cross-validation. Default: 0.75
metrics Character vector, names of the performance metrics selected. The possible values are: "r.squared" (cor(obs, pred) ^ 2), "pseudo.r.squared" (cor(obs, pred)), "rmse" (sqrt(sum((obs - pred)^2)/length(obs)), "nrmse" (rmse/(quantile(obs, 0.75) - quantile(obs, 0.25))), and "auc" (only for binary responses with values 1 and 0). Default: c("r.squared", "pseudo.r.squared", "rmse", "nrmse")
distance.step Numeric, argument distance.step of thinning_til_n(). distance step used during the selection of the centers of the training folds. These fold centers are selected by thinning the data until a number of folds equal or lower than repetitions is reached. Its default value is 1/1000th the maximum distance within records in xy. Reduce it if the number of training folds is lower than expected.
distance.step.x Numeric, argument distance.step.x of make_spatial_folds(). Distance step used during the growth in the x axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the x coordinates).
distance.step.y Numeric, argument distance.step.x of make_spatial_folds(). Distance step used during the growth in the y axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the y coordinates).
grow.testing.folds Logic. By default, this function grows contiguous training folds to keep the spatial structure of the data as intact as possible. However, when setting grow.testing.folds = TRUE, the argument training.fraction is set to 1 - training.fraction, and the training and testing folds are switched. This option might be useful when the training data has a spatial structure that does not match well with the default behavior of the function. Default: FALSE
seed Integer, random seed to facilitate reproducibility. If set to a given number, the results of the function are always the same. Default: 1.
verbose Logical. If TRUE, messages and plots generated during the execution of the function are displayed. Default: TRUE

n.cores Integer, number of cores to use for parallel execution. Creates a socket cluster with parallel::makeCluster(), runs operations in parallel with foreach and %dopar%, and stops the cluster with parallel::clusterStop() when the job is done. Default: parallel::detectCores() - 1

cluster A cluster definition generated with parallel::makeCluster(). If provided, overrides n.cores. When cluster = NULL (default value), and model is provided, the cluster in model, if any, is used instead. If this cluster is NULL, then the function uses n.cores instead. The function does not stop a provided cluster, so it should be stopped with parallel::stopCluster() afterwards. The cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the model argument, or using the %>% pipe. Default: NULL

Details

The evaluation algorithm works as follows: the number of repetitions and the input dataset (stored in model$ranger.arguments$data) are used as inputs for the function thinning_til_n(), that applies thinning() to the input data until as many cases as repetitions are left, and as separated as possible. Each of these remaining records will be used as a "fold center". From that point, the fold grows, until a number of points equal (or close) to training.fraction is reached. The indices of the records within the grown spatial fold are stored as "training" in the output list, and the remaining ones as "testing". Then, for each spatial fold, a "training model" is fitted using the cases corresponding with the training indices, and predicted over the cases corresponding with the testing indices. The model predictions on the "unseen" data are compared with the observations, and the performance measures (R squared, pseudo R squared, RMSE and NRMSE) computed.

Value

A model of the class "rf_evaluate" with a new slot named "evaluation", that is a list with the following slots:

- training.fraction: Value of the argument training.fraction.
- spatial.folds: Result of applying make_spatial_folds() on the data coordinates. It is a list with as many slots as repetitions are indicated by the user. Each slot has two slots named "training" and "testing", each one having the indices of the cases used on the training and testing models.
- per.fold: Data frame with the evaluation results per spatial fold (or repetition). It contains the ID of each fold, its central coordinates, the number of training and testing cases, and the training and testing performance measures: R squared, pseudo R squared (cor(observations, predicted)), rmse, and normalized rmse.
- per.model: Same data as above, but organized per fold and model ("Training", "Testing", and "Full").
- aggregated: Same data, but aggregated by model and performance measure.
Examples

if(interactive()){

}

---

rf_importance

Contribution of each predictor to model transferability

Description

Evaluates the contribution of the predictors to model transferability via spatial cross-validation. The function returns the median increase or decrease in a given evaluation metric (R2, pseudo R2, RMSE, nRMSE, or AUC) when a variable is introduced in a model, by comparing and evaluating via spatial cross-validation models with and without the given variable. This function was devised to provide importance scores that would be less sensitive to spatial autocorrelation than those computed internally by random forest on the out-of-bag data. This function is experimental.

Usage

rf_importance(
  model = NULL,
  xy = NULL,
rf_importance

repetitions = 30,
training.fraction = 0.75,
metric = c("r.squared", "pseudo.r.squared", "rmse", "nrmse", "auc"),
distance.step = NULL,
distance.step.x = NULL,
distance.step.y = NULL,
fill.color = viridis::viridis(100, option = "F", direction = -1, alpha = 1, end = 0.9),
line.color = "white",
seed = 1,
verbose = TRUE,
n.cores = parallel::detectCores() - 1,
cluster = NULL
)

Arguments

model Model fitted with rf() and/or rf_spatial(). The function doesn’t work with models fitted with rf_repeat(). Default: NULL
xy Data frame or matrix with two columns containing coordinates and named "x" and "y". If NULL, the function will throw an error. Default: NULL
repetitions Integer, number of spatial folds to use during cross-validation. Must be lower than the total number of rows available in the model’s data. Default: 30
training.fraction Proportion between 0.5 and 0.9 indicating the proportion of records to be used as training set during spatial cross-validation. Default: 0.75
metric Character, nams of the performance metric to use. The possible values are: "r.squared" (cor(obs, pred) ^ 2), "pseudo.r.squared" (cor(obs, pred)), "rmse" (sqrt(sum((obs - pred)^2)/length(obs)), "nrmse" (rmse/(quantile(obs, 0.75) - quantile(obs, 0.25))), and "auc" (only for binary responses with values 1 and 0). Default: "r.squared"
distance.step Numeric, argument distance.step of thinning_til_n(). distance step used during the selection of the centers of the training folds. These fold centers are selected by thinning the data until a number of folds equal or lower than repetitions is reached. Its default value is 1/1000th the maximum distance within records in xy. Reduce it if the number of training folds is lower than expected.
distance.step.x Numeric, argument distance.step.x of make_spatial_folds(). Distance step used during the growth in the x axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the x coordinates).
distance.step.y Numeric, argument distance.step.x of make_spatial_folds(). Distance step used during the growth in the y axis of the buffers defining the training folds. Default: NULL (1/1000th the range of the y coordinates).
fill.color Character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"), or function generating a palette (e.g. viridis::viridis(100)). Default: viridis::viridis(100, option = "F", direction = -1, alpha = 0.8, end = 0.9)
rf_importance

line.color Character string, color of the line produced by ggplot2::geom_smooth(). Default: "white"

seed Integer, random seed to facilitate reproducibility. If set to a given number, the results of the function are always the same. Default: 1.

verbose Logical. If TRUE, messages and plots generated during the execution of the function are displayed. Default: TRUE

n.cores Integer, number of cores to use for parallel execution. Creates a socket cluster with parallel::makeCluster(), runs operations in parallel with foreach and %dopar%, and stops the cluster with parallel::clusterStop() when the job is done. Default: parallel::detectCores() - 1

cluster A cluster definition generated with parallel::makeCluster(). If provided, overrides n.cores. When cluster = NULL (default value), and model is provided, the cluster in model, if any, is used instead. If this cluster is NULL, then the function uses n.cores instead. The function does not stop a provided cluster, so it should be stopped with parallel::stopCluster() afterwards. The cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the model argument, or using the %>% pipe. Default: NULL

Value

The input model with new data in its "importance" slot. The new importance scores are included in the data frame model$importance$per.variable, under the column names "importance.cv" (median contribution to transferability over spatial cross-validation repetitions), "importance.cv.mad" (median absolute deviation of the performance scores over spatial cross-validation repetitions), "importance.cv.percent" ("importance.cv" expressed as a percent, taking the full model’s performance as baseline), and "importance.cv.mad" (median absolute deviation of "importance.cv"). The plot is stored as "cv.per.variable.plot".

Examples

if(interactive()){

#loading example data
data(plant_richness_df)
data(distance_matrix)
xy <- plant_richness_df[, c("x", "y")]

#fitting random forest model
rf.model <- rf(
  data = plant_richness_df,
  dependent.variable.name = "richness_species_vascular",
  predictor.variable.names = colnames(plant_richness_df)[5:21],
  distance.matrix = distance_matrix,
  distance.thresholds = 0,
  xy = xy,
  n.cores = 1,
  verbose = FALSE
)
rf_repeat

Fits several random forest models on the same data

Description

Fits several random forest models on the same data in order to capture the effect of the algorithm's stochasticity on the variable importance scores, predictions, residuals, and performance measures. The function relies on the median to aggregate performance and importance values across repetitions. It is recommended to use it after a model is fitted (rf() or rf_spatial()), tuned (rf_tuning()), and/or evaluated (rf_evaluate()). This function is designed to be used after fitting a model with rf() or rf_spatial(), tuning it with rf_tuning() and evaluating it with rf_evaluate().

Usage

rf_repeat(
  model = NULL,
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
  distance.matrix = NULL,
  distance.thresholds = NULL,
  xy = NULL,
  ranger.arguments = NULL,
  scaled.importance = FALSE,
  repetitions = 10,
  keep.models = TRUE,
  seed = 1,
  verbose = TRUE,
  n.cores = parallel::detectCores() - 1,
  cluster = NULL
)

Arguments

model A model fitted with rf(). If provided, the data and ranger arguments are taken directly from the model definition (stored in model$ranger.arguments). Default: NULL
data Data frame with a response variable and a set of predictors. Default: NULL
dependent.variable.name
Character string with the name of the response variable. Must be in the column names of data. If the dependent variable is binary with values 1 and 0, the argument case.weights of ranger is populated by the function case_weights(). Default: NULL

predictor.variable.names
Character vector with the names of the predictive variables. Every element of this vector must be in the column names of data. Default: NULL

distance.matrix
Squared matrix with the distances among the records in data. The number of rows of distance.matrix and data must be the same. If not provided, the computation of the Moran’s I of the residuals is omitted. Default: NULL

distance.thresholds
Numeric vector with neighborhood distances. All distances in the distance matrix below each value in distance.thresholds are set to 0 for the computation of Moran’s I. If NULL, it defaults to seq(0, max(distance.matrix), length.out = 4). Default: NULL

xy
(optional) Data frame or matrix with two columns containing coordinates and named “x” and “y”. It is not used by this function, but it is stored in the slot ranger.arguments$xy of the model, so it can be used by rf_evaluate() and rf_tuning(). Default: NULL

ranger.arguments
Named list with ranger arguments (other arguments of this function can also go here). All ranger arguments are set to their default values except for ‘importance’, that is set to 'permutation’ rather than 'none’. Please, consult the help file of ranger if you are not familiar with the arguments of this function.
scaled.importance
Logical. If TRUE, and ‘importance = “permutation”, the function scales ’data’ with scale and fits a new model to compute scaled variable importance scores. Default: FALSE

repetitions
Integer, number of random forest models to fit. Default: 10

keep.models
Logical, if TRUE, the fitted models are returned in the models slot. Set to FALSE if the accumulation of models is creating issues with the RAM memory available. Default: TRUE.

seed
Integer, random seed to facilitate reproducibility. If set to a given number, the results of the function are always the same. Default: 1.

verbose
Logical, if TRUE, messages and plots generated during the execution of the function are displayed. Default: TRUE

n.cores
Integer, number of cores to use for parallel execution. Creates a socket cluster with parallel:::makeCluster(), runs operations in parallel with foreach and %dopar%, and stops the cluster with parallel:::clusterStop() when the job is done. Default: parallel:::detectCores() - 1

cluster
A cluster definition generated with parallel:::makeCluster(). If provided, overrides n.cores. When cluster = NULL (default value), and model is provided, the cluster in model, if any, is used instead. If this cluster is NULL, then the function uses n.cores instead. The function does not stop a provided cluster, so it should be stopped with parallel:::stopCluster() afterwards. The
cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the model argument, or using the %>% pipe. Default: NULL

Value

A ranger model with several new slots:

- `ranger.arguments`: Stores the values of the arguments used to fit the ranger model.
- `importance`: A list containing a data frame with the predictors ordered by their importance, a ggplot showing the importance values, and local importance scores.
- `pseudo.r.squared`: computed as the correlation between the observations and the predictions.
- `residuals`: residuals, normality test of the residuals computed with residuals_test(), and spatial autocorrelation of the residuals computed with moran_multithreshold().

Examples

```r
if(interactive()){

#loading example data
data(plant_richness_df)
data(distance_matrix)

#fitting 5 random forest models
out <- rf_repeat(
  data = plant_richness_df,
  dependent.variable.name = "richness_species_vascular",
  predictor.variable.names = colnames(plant_richness_df)[5:21],
  distance.matrix = distance_matrix,
  distance.thresholds = 0,
  repetitions = 5,
  n.cores = 1
)

#data frame with ordered variable importance
out$importance$per.variable

#per repetition
out$importance$per.repetition

#variable importance plot
out$importance$per.repetition.plot

#performance
out$performance

#spatial correlation of the residuals for different distance thresholds
```
fits spatial random forest models using different methods to generate, rank, and select spatial predictors acting as proxies of spatial processes not considered by the non-spatial predictors. The end goal is providing the model with information about the spatial structure of the data to minimize the spatial correlation (Moran’s I) of the model residuals and generate honest variable importance scores.

**Usage**

```r
rf.spatial(
  model = NULL,
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
  distance.matrix = NULL,
  distance.thresholds = NULL,
  xy = NULL,
  ranger.arguments = NULL,
)```

**Description**

Fits spatial random forest models using different methods to generate, rank, and select spatial predictors acting as proxies of spatial processes not considered by the non-spatial predictors. The end goal is providing the model with information about the spatial structure of the data to minimize the spatial correlation (Moran’s I) of the model residuals and generate honest variable importance scores.

```r
rf.spatial <- rf(
  data = plant_richness_df,
  dependent.variable.name = "richness_species_vascular",
  predictor.variable.names = colnames(plant_richness_df)[8:21],
  distance.matrix = distance_matrix,
  distance.thresholds = 0,
  n.cores = 1
)

rf.repeat <- rf_repeat(
  model = rf.model,
  n.cores = 1
)

rf.repeat$performance
rf.repeat$importance$per.repetition.plot
```
scaled.importance = TRUE,
method = c("mem.moran.sequential", "mem.effect.sequential", "mem.effect.recursive",
  "hengl", "hengl.moran.sequential", "hengl.effect.sequential",
  "hengl.effect.recursive", "pca.moran.sequential", "pca.effect.sequential",
  "pca.effect.recursive"),
max.spatial.predictors = NULL,
weight.r.squared = NULL,
weight.penalization.n.predictors = NULL,
seed = 1,
verbose = TRUE,
n.cores = parallel::detectCores() - 1,
cluster = NULL
)

Arguments

model A model fitted with rf(). If used, the arguments data, dependent.variable.name,
predictor.variable.names,distance.matrix,distance.thresholds,ranger.arguments, and scaled.importance are taken directly from the model definition. Default: NULL
data Data frame with a response variable and a set of predictors. Default: NULL
dependent.variable.name Character string with the name of the response variable. Must be in the column
  names of data. If the dependent variable is binary with values 1 and 0, the argu-
  ment case.weights of ranger is populated by the function case_weights().
  Default: NULL
predictor.variable.names Character vector with the names of the predictive variables. Every element of
  this vector must be in the column names of data. Default: NULL
distance.matrix Squared matrix with the distances among the records in data. The number of
  rows of distance.matrix and data must be the same. If not provided, the
  computation of the Moran's I of the residuals is omitted. Default: NULL
distance.thresholds Numeric vector with distances in the same units as distance.matrix Distances
  below each distance threshold are set to 0 on separated copies of the distance
  matrix to compute Moran's I at different neighborhood distances. If NULL, it
  defaults to seq(0, max(distance.matrix)/2, length.out = 4) (defined by
  default_distance_thresholds()). Default: NULL
xy (optional) Data frame or matrix with two columns containing coordinates and
  named "x" and "y". It is not used by this function, but it is stored in the slot
  ranger.arguments$xy of the model, so it can be used by rf_evaluate() and
  rf_tuning(). Default: NULL
ranger.arguments Named list with ranger arguments (other arguments of this function can also go here). All
  ranger arguments are set to their default values except for 'import-
  ance', that is set to 'permutation' rather than 'none'. Please, consult the help
  file of ranger if you are not familiar with the arguments of this function.
scaled.importance
Logical. If TRUE, and `importance = "permutation"`, the function scales `data` with `scale` and fits a new model to compute scaled variable importance scores. Default: TRUE

method
Character, method to build, rank, and select spatial predictors. One of:
- "hengl"
- "hengl.moran.sequential" (experimental)
- "hengl.effect.sequential" (experimental)
- "hengl.effect.recursive" (experimental)
- "pca.moran.sequential" (experimental)
- "pca.effect.sequential" (experimental)
- "pca.effect.recursive" (experimental)
- "mem.moran.sequential"
- "mem.effect.sequential"
- "mem.effect.recursive"

max.spatial.predictors
Integer, maximum number of spatial predictors to generate. Useful when memory problems arise due to a large number of spatial predictors, Default: NULL

weight.r.squared
Numeric between 0 and 1, weight of R-squared in the selection of spatial components. See Details, Default: NULL

weight.penalization.n.predictors
Numeric between 0 and 1, weight of the penalization for adding an increasing number of spatial predictors during selection. Default: NULL

seed
Integer, random seed to facilitate reproducibility. Default: 1.

verbose
Logical. If TRUE, messages and plots generated during the execution of the function are displayed, Default: TRUE

n.cores
Integer, number of cores to use for parallel execution. Creates a socket cluster with `parallel::makeCluster()`, runs operations in parallel with `foreach` and `%dopar%`, and stops the cluster with `parallel::clusterStop()` when the job is done. Default: `parallel::detectCores() - 1`

cluster
A cluster definition generated with `parallel::makeCluster()`. If provided, overrides `n.cores`. When `cluster = NULL` (default value), and model is provided, the cluster in model, if any, is used instead. If this cluster is NULL, then the function uses `n.cores` instead. The function does not stop a provided cluster, so it should be stopped with `parallel::stopCluster()` afterwards. The cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the `model` argument, or using the `%>%` pipe. Default: NULL

Details
The function uses three different methods to generate spatial predictors ("hengl", "pca", and "mem"), two methods to rank them in order to define in what order they are introduced in the model ("effect" and "moran"), and two methods to select the spatial predictors that minimize the spatial correlation.
of the model residuals ("sequential" and "recursive"). All method names but "hengl" (that uses the complete distance matrix as predictors in the spatial model) are named by combining a method to generate the spatial predictors, a method to rank them, and a method to select them, separated by a point. Examples are "mem.moran.sequential" or "mem.effect.recursive". All combinations are not possible, since the ranking method "moran" cannot be used with the selection method "recursive" (because the logics behind them are very different, see below). Methods to generate spatial predictors:

- "hengl": named after the method RFsp presented in the paper "Random forest as a generic framework for predictive modeling of spatial and spatio-temporal variables", by Hengl et al. (2018), where the authors propose to use the distance matrix among records as predictors in spatial random forest models (RFsp method). In this function, all methods starting with "hengl" use either the complete distance matrix, or select columns of the distance matrix as spatial predictors.

- "mem": Generates Moran’s Eigenvector Maps, that is, the eigenvectors of the double-centered weights of the distance matrix. The method is described in "Spatial modelling: a comprehensive framework for principal coordinate analysis of neighbour matrices (PCNM)" by Dray et al. (2006), and "Statistical methods for temporal and space–time analysis of community composition data" by Legendre and Gauthier (2014).

- "pca": Computes spatial predictors from the principal component analysis of a weighted distance matrix (see weights_from_distance_matrix()). This is an experimental method, use with caution.

Methods to rank spatial predictors (see rank_spatial_predictors()):

- "moran": Computes the Moran’s I of each spatial predictor, selects the ones with positive values, and ranks them from higher to lower Moran’s I.

- "effect": If a given non-spatial random forest model is defined as \( y = p_1 + \ldots + p_n \), being \( p_1 + \ldots + p_n \) the set of predictors, for every spatial predictor generated (spX) a spatial model \( y = p_1 + \ldots + p_n + spX \) is fitted, and the Moran’s I of its residuals is computed. The spatial predictors are then ranked by how much they help to reduce spatial autocorrelation between the non-spatial and the spatial model.

Methods to select spatial predictors:

- "sequential" (see select_spatial_predictors_sequential()): The spatial predictors are added one by one in the order they were ranked, and once all spatial predictors are introduced, the best first n predictors are selected. This method is similar to the one employed in the MEM methodology (Moran’s Eigenvector Maps) described in the paper "Spatial modelling: a comprehensive framework for principal coordinate analysis of neighbour matrices (PCNM)" by Dray et al. (2006), and "Statistical methods for temporal and space–time analysis of community composition data" by Legendre and Gauthier (2014). This method generally introduces tens of predictors into the model, but usually offers good results.

- "recursive" (see select_spatial_predictors_recursive()): This method tries to find the smallest combination of spatial predictors that reduce the spatial correlation of the model’s residuals the most. The algorithm goes as follows: 1. The first ranked spatial predictor is introduced into the model; 2. the remaining predictors are ranked again using the "effect" method, using the model in 1. as reference. The first spatial predictor in the resulting ranking is then introduced into the model, and the steps 1. and 2. are repeated until spatial predictors
stop having an effect in reducing the Moran’s I of the model residuals. This method takes longer to compute, but generates smaller sets of spatial predictors. This is an experimental method, use with caution.

Once ranking procedure is completed, an algorithm is used to select the minimal subset of spatial predictors that reduce the most the Moran’s I of the residuals: for each new spatial predictor introduced in the model, the Moran’s I of the residuals, its p-value, a binary version of the p-value (0 if < 0.05 and 1 if >= 0.05), the R-squared of the model, and a penalization linear with the number of spatial predictors introduced (computed as \((1 / \text{total spatial predictors}) \times \text{introduced spatial predictors}\)) are rescaled between 0 and 1. Then, the optimization criteria is computed as \(\max(1 - \text{Moran's I}, \text{p-value binary}) + \text{weight} \times \text{R-squared} - \text{weight} \times \text{penalization}\). The predictors from the first one to the one with the highest optimization criteria are then selected as the best ones in reducing the spatial correlation of the model residuals, and used along with data to fit the final spatial model.

**Value**

A ranger model with several new slots:

- **ranger.arguments**: Values of the arguments used to fit the ranger model.
- **importance**: A list containing the vector of variable importance as originally returned by ranger (scaled or not depending on the value of 'scaled.importance'), a data frame with the predictors ordered by their importance, and a ggplot showing the importance values.
- **performance**: With the out-of-bag R squared, pseudo R squared, RMSE and NRMSE of the model.
- **residuals**: residuals, normality test of the residuals computed with `residuals_test()`, and spatial autocorrelation of the residuals computed with `moran_multithreshold()`.
- **spatial**: A list with four slots:
  - **method**: Character, method used to generate, rank, and select spatial predictors.
  - **names**: Character vector with the names of the selected spatial predictors. Not returned if the method is "hengl".
  - **optimization**: Criteria used to select the spatial predictors. Not returned if the method is "hengl".
  - **plot**: Plot of the criteria used to select the spatial predictors. Not returned if the method is "hengl".

**Examples**

```r
if(interactive()){
  #loading example data
data(distance_matrix)
data(plant_richness_df)

  #names of the response and predictors
dependent.variable.name <- "richness_species_vascular"
predictor.variable.names <- colnames(plant_richness_df)[5:21]

  #hengl
  model <- rf_spatial(
```
data = plant_richness_df,
dependent.variable.name = dependent.variable.name,
predictor.variable.names = predictor.variable.names,
distance.matrix = distance_matrix,
distance.thresholds = 0,
method = "hengl",
n.cores = 1
)

#mem.moran.sequential
model <- rf_spatial(
data = plant_richness_df,
dependent.variable.name = dependent.variable.name,
predictor.variable.names = predictor.variable.names,
distance.matrix = distance_matrix,
distance.thresholds = 0,
method = "mem.moran.sequential",
n.cores = 1
)

#fitting an rf_spatial model from an rf model

rf.spatial$spatial.correlation.residuals$plot

rf_tuning

Tuning of random forest hyperparameters via spatial cross-validation

Description

Finds the optimal set of random forest hyperparameters num.trees, mtry, and min.node.size via grid search by maximizing the model’s R squared, or AUC, if the response variable is binomial, via spatial cross-validation performed with rf_evaluate().
Usage

rf_tuning(
  model = NULL,
  num.trees = NULL,
  mtry = NULL,
  min.node.size = NULL,
  xy = NULL,
  repetitions = 30,
  training.fraction = 0.75,
  seed = 1,
  verbose = TRUE,
  n.cores = parallel::detectCores() - 1,
  cluster = NULL
)

Arguments

model  A model fitted with rf(). If provided, the training data is taken directly from
        the model definition (stored in model$ranger.arguments). Default: NULL
num.trees Numeric integer vector with the number of trees to fit on each model repetition.
        Default: c(500, 1000, 2000).
mtry  Numeric integer vector, number of predictors to randomly select from the com-
       complete pool of predictors on each tree split. Default: floor(seq(1, length(predictor.variable.names),
              length.out = 4))
min.node.size Numeric integer, minimal number of cases in a terminal node. Default: c(5,
        10, 20, 40)
xy     Data frame or matrix with two columns containing coordinates and named "x"
        and "y". If NULL, the function will throw an error. Default: NULL
repetitions Integer, number of independent spatial folds to use during the cross-validation.
        Default: 30.
training.fraction Proportion between 0.2 and 0.9 indicating the number of records to be used in
        model training. Default: 0.75
seed   Integer, random seed to facilitate reproducibility. If set to a given number, the
        results of the function are always the same. Default: 1.
verbose Logical. If TRUE, messages and plots generated during the execution of the function
        are displayed. Default: TRUE
n.cores Integer, number of cores to use for parallel execution. Creates a socket cluster
        with parallel::makeCluster(), runs operations in parallel with foreach and
        %dopar%, and stops the cluster with parallel::clusterStop() when the job
        is done. Default: parallel::detectCores() - 1
cluster A cluster definition generated with parallel::makeCluster(). If provided,
        overrides n.cores. When cluster = NULL (default value), and model is pro-
        vided, the cluster in model, if any, is used instead. If this cluster is NULL, then
        the function uses n.cores instead. The function does not stop a provided clus-
        ter, so it should be stopped with parallel::stopCluster() afterwards. The
cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the model argument, or using the %>% pipe. Default: NULL

Value

A model with a new slot named tuning, with a data frame with the results of the tuning analysis.

rf_evaluate()

Examples

if(interactive()){  
  #loading example data  
  data(plant_richness_df)  
  data(distance_matrix)

  #fitting model to tune  
  out <- rf(  
    data = plant_richness_df,  
    dependent.variable.name = "richness_species_vascular",  
    predictor.variable.names = colnames(plant_richness_df)[5:21],  
    distance.matrix = distance_matrix,  
    distance.thresholds = 0,  
    n.cores = 1  
  )

  #model tuning  
  tuning <- rf_tuning(  
    model = out,  
    num.trees = c(100, 500),  
    mtry = c(2, 8),  
    min.node.size = c(5, 10),  
    xy = plant_richness_df[, c("x", "y")],  
    n.cores = 1  
  )
}

root_mean_squared_error

RMSE and normalized RMSE

Description

Computes the rmse or normalized rmse (nrmse) between two numeric vectors of the same length representing observations and model predictions.
Usage

```r
root_mean_squared_error(
  o,
  p,
  normalization = c("rmse", "all", "mean", "sd", "maxmin", "iq")
)
```

Arguments

- `o`: Numeric vector with observations, must have the same length as `p`.
- `p`: Numeric vector with predictions, must have the same length as `o`.
- `normalization`: character, normalization method, Default: "rmse" (see Details).

Details

The normalization methods go as follows:

- "rmse": RMSE with no normalization.
- "mean": RMSE divided by the mean of the observations (rmse/mean(o)).
- "sd": RMSE divided by the standard deviation of the observations (rmse/sd(o)).
- "maxmin": RMSE divided by the range of the observations (rmse/(max(o) - min(o))).
- "iq": RMSE divided by the interquartile range of the observations (rmse/(quantile(o, 0.75) - quantile(o, 0.25)))

Value

Named numeric vector with either one or 5 values, as selected by the user.

Examples

```r
if(interactive()){
  root_mean_squared_error(
    o = runif(10),
    p = runif(10)
  )
}
```
select_spatial_predictors_recursive

Finds optimal combinations of spatial predictors

Description

Selects spatial predictors following these steps:

1. Gets the spatial predictors ranked by `rank.spatial.predictors()` and fits a model of the form \( y \sim \text{predictors} + \text{best.spatial.predictor}_1 \). The Moran’s I of the residuals of this model is used as reference value for the next step.

2. The remaining spatial predictors are introduced again into `rank.spatial.predictors()`, and the spatial predictor with the highest ranking is introduced in a new model of the form \( y \sim \text{predictors} + \text{best.spatial.predictor}_1 + \text{best.spatial.predictor}_2 \).

3. Steps 1 and 2 are repeated until the Moran’s I doesn’t improve for a number of repetitions equal to the 20 percent of the total number of spatial predictors introduced in the function.

This method allows to select the smallest set of spatial predictors that have the largest joint effect in reducing the spatial correlation of the model residuals, while maintaining the model’s R-squared as high as possible. As a consequence of running `rank.spatial.predictors()` on each iteration, this method includes in the final model less spatial predictors than the sequential method implemented in `select.spatial.predictors_sequential()` would do, while minimizing spatial correlation and maximizing the R squared of the model as much as possible.

Usage

```r
select.spatial.predictors_recursive(
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
  distance.matrix = NULL,
  distance.thresholds = NULL,
  ranger.arguments = NULL,
  spatial.predictors.df = NULL,
  spatial.predictors.ranking = NULL,
  weight.r.squared = 0.25,
  weight.penalization.n.predictors = 0,
  n.cores = parallel::detectCores() - 1,
  cluster = NULL
)
```

Arguments

data Data frame with a response variable and a set of predictors. Default: NULL
dependent.variable.name Character string with the name of the response variable. Must be in the column names of data. Default: NULL
predictor.variable.names
   Character vector with the names of the predictive variables. Every element of
   this vector must be in the column names of data. Default: NULL

distance.matrix
   Squared matrix with the distances among the records in data. The number of
   rows of distance.matrix and data must be the same. If not provided, the
   computation of the Moran’s I of the residuals is omitted. Default: NULL

distance.thresholds
   Numeric vector with neighborhood distances. All distances in the distance ma-
   trix below each value in distance.thresholds are set to 0 for the computation
   of Moran’s I. If NULL, it defaults to seq(0, max(distance.matrix), length.out = 4).
   Default: NULL

ranger.arguments
   Named list with ranger arguments (other arguments of this function can also go
   here). All ranger arguments are set to their default values except for ‘import-
   tance’, that is set to ’permutation’ rather than ’none’. Please, consult the help
   file of ranger if you are not familiar with the arguments of this function.

spatial.predictors.df
   Data frame of spatial predictors.

spatial.predictors.ranking
   Ranking of predictors returned by rank_spatial_predictors().

weight.r.squared
   Numeric between 0 and 1, weight of R-squared in the optimization index. De-
   fault: 0.25

weight.penalization.n.predictors
   Numeric between 0 and 1, weight of the penalization for the number of spatial
   predictors added in the optimization index. Default: 0

n.cores
   Integer, number of cores to use. Default: parallel::detectCores() - 1

cluster
   A cluster definition generated by parallel::makeCluster(). Default: NULL

Details

The algorithm works as follows. If the function rank_spatial_predictors() returns 10 ranked
spatial predictors (sp1 to sp10, being sp7 the best one), select_spatial_predictors_recursive() is
going to first fit the model y ~ predictors + sp7. Then, the spatial predictors sp2 to sp9 are
again ranked with rank_spatial_predictors() using the model y ~ predictors + sp7 as refer-
ence (at this stage, some of the spatial predictors might be dropped due to lack of effect). When
the new ranking of spatial predictors is ready (let’s say they are sp5, sp3, and sp4), the best one
(sp5) is included in the model y ~ predictors + sp7 + sp5, and the remaining ones go again to
rank_spatial_predictors() to repeat the process until spatial predictors are depleted.

Value

A list with two slots: optimization, a data frame with the index of the spatial predictor added on
each iteration, the spatial correlation of the model residuals, and the R-squared of the model, and
best.spatial.predictors, that is a character vector with the names of the spatial predictors that
minimize the Moran’s I of the residuals and maximize the R-squared of the model.
select_spatial_predictors_recursive

Examples

if(interactive()){
    #loading example data
    data(distance_matrix)
    data(plant_richness_df)
    
    #response and predictor names
    dependent.variable.name = "richness_species_vascular"
    predictor.variable.names = colnames(plant_richness_df)[5:21]
    
    #non-spatial model
    model <- rf(
        data = plant_richness_df,
        dependent.variable.name = dependent.variable.name,
        predictor.variable.names = predictor.variable.names,
        distance.matrix = distance_matrix,
        distance.thresholds = 0,
        n.cores = 1
    )
    
    #preparing spatial predictors
    spatial.predictors <- mem_multithreshold(
        distance.matrix = distance_matrix,
        distance.thresholds = 0
    )
    
    #ranking spatial predictors
    spatial.predictors.ranking <- rank_spatial_predictors(
        data = plant_richness_df,
        dependent.variable.name = dependent.variable.name,
        predictor.variable.names = predictor.variable.names,
        spatial.predictors.df = spatial.predictors,
        ranking.method = "moran",
        reference.moran.i = model$spatial.correlation.residuals$max.moran,
        distance.matrix = distance_matrix,
        distance.thresholds = 0,
        n.cores = 1
    )
    
    #selecting the best subset of predictors
    selection <- select_spatial_predictors_recursive(
        data = plant_richness_df,
        dependent.variable.name = dependent.variable.name,
        predictor.variable.names = predictor.variable.names,
        distance.matrix = distance_matrix,
        distance.thresholds = 0,
        spatial.predictors.df = spatial.predictors,
        spatial.predictors.ranking = spatial.predictors.ranking,
        n.cores = 1
    )
select_spatial_predictors_sequential

Description

Selects spatial predictors by adding them sequentially into a model while monitoring the Moran’s I of the model residuals and the model’s R-squared. Once all the available spatial predictors have been added to the model, the function identifies the first \( n \) predictors that minimize the spatial correlation of the residuals and maximize R-squared, and returns the names of the selected spatial predictors and a data frame with the selection criteria.

Usage

```r
select_spatial_predictors_sequential(
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
  distance.matrix = NULL,
  distance.thresholds = NULL,
  ranger.arguments = NULL,
  spatial.predictors.df = NULL,
  spatial.predictors.ranking = NULL,
  weight.r.squared = 0.75,
  weight.penalization.n.predictors = 0.25,
  verbose = FALSE,
  n.cores = parallel::detectCores() - 1,
  cluster = NULL
)
```

Arguments

data	Data frame with a response variable and a set of predictors. Default: NULL
dependent.variable.name	Character string with the name of the response variable. Must be in the column names of data. Default: NULL
predictor.variable.names	Character vector with the names of the predictive variables. Every element of this vector must be in the column names of data. Default: NULL
**Details**

The algorithm works as follows: If the function \texttt{rank.spatial.predictors} returns 10 spatial predictors (sp1 to sp10, ordered from best to worst), \texttt{select.spatial.predictors_sequential} is going to fit the models \texttt{y ~ predictors + sp1}, \texttt{y ~ predictors + sp1 + sp2}, until all spatial predictors are used in \texttt{y ~ predictors + sp1 ... sp10}. The model with lower Moran’s I of the residuals and higher R-squared (computed on the out-of-bag data) is selected, and its spatial predictors returned.

**Value**

A list with two slots: \texttt{optimization}, a data frame with the index of the spatial predictor added on each iteration, the spatial correlation of the model residuals, and the R-squared of the model, and \texttt{best.spatial.predictors}, that is a character vector with the names of the spatial predictors that minimize the Moran’s I of the residuals and maximize the R-squared of the model.

**Examples**

```r
if(interactive()){
```
#loading example data
data(distance_matrix)
data(plant_richness_df)

#common arguments
dependent.variable.name = "richness_species_vascular"
predictor.variable.names = colnames(plant_richness_df)[5:21]

#non-spatial model
model <- rf(
  data = plant_richness_df,
  dependent.variable.name = dependent.variable.name,
  predictor.variable.names = predictor.variable.names,
  distance.matrix = distance_matrix,
  distance.thresholds = 0,
  n.cores = 1
)

#preparing spatial predictors
spatial.predictors <- mem_multithreshold(
  distance.matrix = distance_matrix,
  distance.thresholds = 0
)

#ranking spatial predictors by their Moran's I (faster option)
spatial.predictors.ranking <- rank_spatial_predictors(
  ranking.method = "moran",
  spatial.predictors.df = spatial.predictors,
  reference.moran.i = model$spatial.correlation.residuals$max.moran,
  distance.matrix = distance_matrix,
  distance.thresholds = 0,
  n.cores = 1
)

#selecting the best subset of predictors
selection <- select_spatial_predictors_sequential(
  data = plant_richness_df,
  dependent.variable.name = dependent.variable.name,
  predictor.variable.names = predictor.variable.names,
  distance.matrix = distance_matrix,
  distance.thresholds = 0,
  spatial.predictors.df = spatial.predictors,
  spatial.predictors.ranking = spatial.predictors.ranking,
  n.cores = 1
)

selection$optimization
selection$best.spatial.predictors
plot_optimization(selection$optimization)
**standard_error**

*Standard error of the mean of a numeric vector*

**Description**

Computes the standard error of the mean of a numeric vector as `round(sqrt(var(x)/length(x)), 3)`

**Usage**

```r
standard_error(x)
```

**Arguments**

- `x` A numeric vector.

**Details**

The function removes `NA` values before computing the standard error, and rounds the result to 3 decimal places.

**Value**

A numeric value.

**Examples**

```r
if(interactive()){
  standard_error(runif(10))
}
```

---

**statistical_mode**

*Statistical mode of a vector*

**Description**

Computes the mode of a numeric or character vector

**Usage**

```r
statistical_mode(x)
```

**Arguments**

- `x` Numeric or character vector.
Description

Suggests candidate variable interactions and composite features able to improve predictive accuracy over data not used to train the model via spatial cross-validation with `rf_evaluate()`. For a pair of predictors a and b, interactions are build via multiplication (a * b), while composite features are built by extracting the first factor of a principal component analysis performed with `pca()`, after rescaling a and b between 1 and 100. Interactions and composite features are named a..x..b and a..pca..b respectively.

Candidate variables a and b are selected from those predictors in `predictor.variable.names` with a variable importance above `importance.threshold` (set by default to the median of the importance scores).

For each interaction and composite feature, a model including all the predictors plus the interaction or composite feature is fitted, and it's R squared (or AUC if the response is binary) computed via spatial cross-validation (see `rf_evaluate()`) is compared with the R squared of the model without interactions or composite features.

From all the potential interactions screened, only those with a positive increase in R squared (or AUC when the response is binomial) of the model, a variable importance above the median, and a maximum correlation among themselves and with the predictors in `predictor.variable.names` not higher than `cor.threshold` (set to 0.5 by default) are selected. Such a restrictive set of rules ensures that the selected interactions can be used right away for modeling purposes without increasing model complexity unnecessarily. However, the suggested variable interactions might not make sense from a domain expertise standpoint, so please, examine them with care.

The function returns the criteria used to select the interactions, and the data required to use these interactions a model.

Usage

```r
the_feature_engineer(
  data = NULL,
  dependent.variable.name = NULL,
  predictor.variable.names = NULL,
)```
xy = NULL,
ranger.arguments = NULL,
repetitions = 30,
training.fraction = 0.75,
importance.threshold = 0.75,
cor.threshold = 0.75,
point.color = viridis::viridis(100, option = "F", alpha = 0.8),
seed = NULL,
verbose = TRUE,
n.cores = parallel::detectCores() - 1,
cluster = NULL
)

Arguments

data  Data frame with a response variable and a set of predictors. Default: NULL

dependent.variable.name  Character string with the name of the response variable. Must be in the column names of data. If the dependent variable is binary with values 1 and 0, the argument case.weights of ranger is populated by the function case_weights(). Default: NULL

predictor.variable.names  Character vector with the names of the predictive variables, or object of class "variable_selection" produced by auto_vif() and/or auto_cor(). Every element of this vector must be in the column names of data. Default: NULL

xy  Data frame or matrix with two columns containing coordinates and named "x" and "y". If not provided, the comparison between models with and without variable interactions is not done.

ranger.arguments  Named list with ranger arguments (other arguments of this function can also go here). All ranger arguments are set to their default values except for 'importance', that is set to 'permutation' rather than 'none'. Please, consult the help file of ranger if you are not familiar with the arguments of this function.

repetitions  Integer, number of spatial folds to use during cross-validation. Must be lower than the total number of rows available in the model's data. Default: 30

training.fraction  Proportion between 0.5 and 0.9 indicating the proportion of records to be used as training set during spatial cross-validation. Default: 0.75

importance.threshold  Numeric between 0 and 1, quantile of variable importance scores over which to select individual predictors to explore interactions among them. Larger values reduce the number of potential interactions explored. Default: 0.75

cor.threshold  Numeric, maximum Pearson correlation between any pair of the selected interactions, and between any interaction and the predictors in predictor.variable.names. Default: 0.75

point.color  Colors of the plotted points. Can be a single color name (e.g. "red4"), a character vector with hexadecimal codes (e.g. "#440154FF" "#21908CFF" "#FDE725FF"),
or function generating a palette (e.g. `viridis::viridis(100)`). Default: `viridis::viridis(100, option = "F", alpha = 0.8)`

**seed**

Integer, random seed to facilitate reproducibility. If set to a given number, the results of the function are always the same. Default: NULL

**verbose**

Logical. If TRUE, messages and plots generated during the execution of the function are displayed. Default: TRUE

**n.cores**

Integer, number of cores to use for parallel execution. Creates a socket cluster with `parallel::makeCluster()`, runs operations in parallel with `foreach` and `%dopar%`, and stops the cluster with `parallel::clusterStop()` when the job is done. Default: `parallel::detectCores() - 1`

**cluster**

A cluster definition generated with `parallel::makeCluster()`. If provided, overrides `n.cores`. When `cluster = NULL` (default value), and `model` is provided, the cluster in `model`, if any, is used instead. If this cluster is NULL, then the function uses `n.cores` instead. The function does not stop a provided cluster, so it should be stopped with `parallel::stopCluster()` afterwards. The cluster definition is stored in the output list under the name "cluster" so it can be passed to other functions via the `model` argument, or using the `%>%` pipe. Default: NULL

**Value**

A list with seven slots:

- **screening**: Data frame with selection scores of all the interactions considered.
- **selected**: Data frame with selection scores of the selected interactions.
- **df**: Data frame with the computed interactions.
- **plot**: List of plots of the selected interactions versus the response variable. The output list can be plotted all at once with `patchwork::wrap_plots(p)` or `cowplot::plot_grid(plotlist = p)`, or one by one by extracting each plot from the list.
- **data**: Data frame with the response variable, the predictors, and the selected interactions, ready to be used as `data` argument in the package functions.
- **dependent_variable.name**: Character, name of the response.
- **predictor_variable.names**: Character vector with the names of the predictors and the selected interactions.

**Examples**

```r
if(interactive()){

# load example data
data(plant_richness_df)

new.features <- the_feature_engineer(
    data = plant_richness_df,
    dependent.variable.name = "richness_species_vascular",
    predictor.variable.names = colnames(plant_richness_df)[5:21],
    n.cores = 1,
```

```
### thinning

Applies thinning to pairs of coordinates

**Description**

Resamples a set of points with x and y coordinates to impose a minimum distance among nearby points.

**Usage**

```r
thinning(xy, minimum.distance = NULL)
```

**Arguments**

- `xy` A data frame with columns named "x" and "y" representing geographic coordinates.
- `minimum.distance` Numeric, minimum distance to be set between nearby points, in the same units as the coordinates of `xy`.

**Details**

Generally used to remove redundant points that could produce pseudo-replication, and to limit sampling bias by disaggregating clusters of points.

**Value**

A data frame with the same columns as `xy` with points separated by the defined minimum distance.

**See Also**

`thinning_til_n()`
Examples

if(interactive()){

# load example data
data(plant_richness_df)

# thinning to points separated by 5 degrees
plant_richness.thin <- thinning(
  x = plant_richness_df,
  minimum.distance = 5 # points separated by at least 5 degrees
)

plant_richness.thin
}

thinning_til_n

Applies thinning to pairs of coordinates until reaching a given n

Description

Resamples a set of points with x and y coordinates by increasing the distance step by step until a given sample size is obtained.

Usage

thinning_til_n(xy, n = 30, distance.step = NULL)

Arguments

(xy) A data frame with columns named "x" and "y" representing geographic coordinates. Default: NULL
(n) Integer, number of samples to obtain. Must be lower than nrow(xy). Default: 30
(distance.step) Numeric, distance step used during the thinning iterations. If NULL, the one percent of the maximum distance among points in xy is used. Default: NULL

Value

A data frame with the same columns as xy with a row number close to n.

See Also

thinning()
vif

Examples

if(interactive()){
  #loading example data
  data(plant_richness_df)

  #thinning to ~20 records
  plant_richness.thin <- thinning_til_n(
    x = plant_richness_df,
    n = 20
  )

  plant_richness.thin
}

vif

Variance Inflation Factor of a data frame

Description

Computes the variance inflation factor (VIF) of the columns in a data frame. Warning: variables in preference.order not in colnames(x), and non-numeric columns are removed silently from x and preference.order. The same happens with rows having NA values (na.omit() is applied). The function issues a warning if zero-variance columns are found.

Usage

vif(x)

Arguments

x Data frame with numeric columns, typically containing a set of model predictors.

Value

A data frame with two columns having the name of the variables in ‘x’ and their respective VIF values.

See Also

auto_vif(), auto_cor()
weights_from_distance_matrix

Transforms a distance matrix into a matrix of weights

Description

Transforms a distance matrix into weights (1/distance.matrix) normalized by the row sums. Used to compute Moran’s I values and Moran’s Eigenvector Maps. Allows to apply a threshold to the distance matrix before computing the weights.

Usage

weights_from_distance_matrix(
  distance.matrix = NULL,
  distance.threshold = 0
)

Arguments

distance.matrix
  Distance matrix. Default: NULL.
distance.threshold
  Numeric, positive, in the range of values of distance.matrix. Distances below this value in the distance matrix are set to 0., Default: 0.

Value

A weighted distance matrix.

Examples

if(interactive()){
  #loading example distance matrix
data(distance_matrix)

  #computing matrix of weights
  distance.matrix.weights <- weights_from_distance_matrix(
    distance.matrix = distance_matrix
  )
weights_from_distance_matrix

)

distance_matrix.weights

}
