### Package ‘states’

**Type**  Package  

**Title**  Create Panels of Independent States  

**Version**  0.3.2  

**Maintainer**  Andreas Beger  

**Description**  Create panel data consisting of independent states from 1816 to the present. The package includes the Gleditsch & Ward (G&W) and Correlates of War (COW) lists of independent states, as well as helper functions for working with state panel data and standardizing other data sources to create country-year/month/etc. data.  

**License**  MIT + file LICENSE  

**Encoding**  UTF-8  

**LazyData**  true  

**Depends**  R (>= 2.10)  

**Imports**  dplyr, rlang, methods, lifecycle  

**Suggests**  testthat (>= 2.1.0), ggplot2, stringr, knitr, rmarkdown, covr, pkgdown, DT  

**RoxygenNote**  7.2.3  

**VignetteBuilder**  knitr  

**BugReports**  https://github.com/andybega/states/issues  

**Config/testthat/edition**  3  

**NeedsCompilation**  no  

**Author**  Andreas Beger [cre, aut] (<https://orcid.org/0000-0003-1883-3169>)  

**Repository**  CRAN  

**Date/Publication**  2023-09-05 12:20:02 UTC
### Description

Check set overlap between two state lists / data frames, e.g. prior to merging them.

### Usage

```r
compare(
  df1,
  df2,
  state1 = "gwcode",
  time1 = "year",
  state2 = "gwcode",
  time2 = "year"
)
```

`report(x)`

### Arguments

- `df1` data frame
- `df2` data frame
- `state1` (character(1)) Name of the country ID var in df1, default "gwcode"
- `time1` (character(1)) Name of the time ID var in df1, default "year"
- `state2` (character(1)) Name of the country ID var in df2, default "gwcode"
- `time2` (character(1)) Name of the time ID var in df2, default "year"
- `x` a "state_sets" object produced by `compare()`
Details

This is a helper for interactively debugging data merges for data that may have slightly different state lists. For example, these differences in case sets could be because of country code differences.

Examples

```r
# df2 has all countries in 2018 but some values in x1 are missing
df1 <- state_panel(2018, 2018, partial = "any")
df1$x1 <- round(runif(nrow(df1))*5)
df1$x1[sample.int(nrow(df1), size = 20, replace = FALSE)] <- NA

# df2 is missing some countries and also has missing values in x2
df2 <- state_panel(2018, 2018, partial = "any")
df2 <- df2[sample.int(nrow(df2), size = 150), ]
df2$x2 <- round(runif(nrow(df2))*5)
df2$x2[sample.int(nrow(df2), size = 20, replace = FALSE)] <- NA

comp <- compare(df1, df2)
comp

report(comp)
```

country_names

---

### Description

Country names

### Usage

```r
country_names(x, list = "GW", shorten = FALSE)
```

### Arguments

- **x**
  - **numeric()**
  - A vector of numeric country codes

- **list**
  - **logical(1)**
  - Which states list to use? Only "GW" at this time.

- **shorten**
  - **logical(1)**
  - Shorten some of the longer country names like "Macedonia, the former Yugoslav Republic of"?
Examples

data("gwstates")
codes <- gwstates$gwcode
cn <- country_names(codes)
cs <- country_names(codes, shorten = TRUE)
data.frame(gwcode = codes, country_name = cn, short_names = cs)

cowstates  Correlates of War list of independent states

Description

A list of independent states and microstates from 1816 on by the Correlates of War project.

Usage
cowstates

Format

Data frame

ccode  Gleditsch and Ward country code.
cowc  ISO 3 character country code.
country_name  Long form country name
start  Country start of independence.
end  Country end of independence.
microstate  Logical flag for whether state is a microstates with less than 250,000 population.

Source

Examples
data(cowstates)
head(cowstates)
gwstates  

---

**gwstates**  

*Gleditsch and Ward list of independent states*

## Description

A list of independent states and microstates from 1816 on by Gleditsch and Ward

## Usage

gwstates

## Format

Data frame

- **gwcode**: Gleditsch and Ward country code.
- **gwc**: G&W character country code. This is derived from the COW character codes.
- **country_name**: Long form country name
- **start**: Country start of independence.
- **end**: Country end of independence.
- **microstate**: Logical flag for whether state is a microstates with less than 250,000 population.

## Source

## References

## Examples

data(gwstates)  
head(gwstates)
id_date_sequence  Identify date sequences

Description
For correctly plotting country-time period spells

Usage
id_date_sequence(x, pd = NULL)

Arguments
x
a Date sequence
pd
what is the time aggregation period in the data?

Examples
library("ggplot2")
d1 <- as.Date("2018-01-01")
d2 <- as.Date("2025-01-01")
seq1 <- seq(d1, d2, by = "year")
data.frame(seq1, id=id_date_sequence(seq1, "year"))
# With a gap, should be two ids
df <- data.frame(date = seq1[-4], id=id_date_sequence(seq1[-4], "year"), cowcode = 999)
df

# The point is to plot countries with interrupted independence correctly:
df$y <- c(rep(1, 3), rep(2, 4))
df$id <- paste0(df$cowcode, df$id)
df
ggplot(df, aes(x = date, y = y, group = cowcode)) + geom_line()
ggplot(df, aes(x = date, y = y, group = id)) + geom_line()

# Shortcut for integer years:
data.frame(year = yr, id = id_date_sequence(yr))

parse_date  Parse date

Description
Try to parse input as a date

Usage
parse_date(x)
plot_missing

Arguments

x  a integer or character vector, see examples

Examples

parse_date(2006)
parse_date("2006")
parse_date("2006-06")
parse_date("2006-06-01")
parse_date(as.Date("2006-06-01"))

plot_missing

Visualize missing and non-proper cases for state panel data

Description

Plot missing values by country and date, and additionally identify country-date cases that do or do not match an independent state list.

Usage

plot_missing(
  data,
  x = NULL,
  ccode = NULL,
  time = NULL,
  period = NULL,
  statelist = NULL,
  partial = "any",
  skip_labels = 5,
  space = deprecated()
)

missing_info(
  data,
  x = NULL,
  ccode = NULL,
  time = NULL,
  period = NULL,
  statelist = NULL,
  partial = NULL,
  space = deprecated()
)
plot_missing

Arguments

data State panel data frame
x Variable names(s), e.g. "x" or c("x1", "x2"). Default is NULL, in which case all columns expect the ccode and time ID columns will be used.
ccode Name of variable identifying state country codes. If NULL (default) and one of "gwcode" or "cowcode" is a column in the data, it will be used.
time Name of time identifier. If NULL and a "date" or "year" column are in the data, they will be used ("year", preferentially, if both are present)
period Time period in which the data are. NULL by default and inferred to be "year" if the "time" column has name "year" or contains integers with a range between 1799 and 2050. Required if the "time" column is a base::Date() vector to avoid ambiguity.
statelist Check not only missing values, but presence or absence of observations against a list of independent states? One of "GW", "COW" or "none". NULL by default, in which case it will be inferred if the ccode columns have the name "gwcode" or "cowcode", and "none" otherwise.
partial Option for how to handle edge cases where a state is independent for only part of a time period (year, month, etc.). Options include "exact", and "any". See state_panel() for details. If NULL (default) and the "time" column is a date, it will be set to "exact", for yearly "time" columns it will be set to "any".
skip_labels Only plot the label for every n-th country on the y-axis to avoid overplotting.
space Deprecated, use "ccode" argument instead.

details

missing_info provides the information that is plotted with plot_missing. The latter returns a ggplot, and thus can be chained with other ggplot functions as usual.

Value

plot_missing returns a ggplot2 object.
missing_info returns a data frame with components:

code ccode identifier, with name equal to the "ccode" argument, e.g. "ccode".
time Time identifier, with name equal to the "time" argument, e.g. "date".
independent A logical vector, is the statelist argument is none, NA.
missing_value A logical vector indicating if that record has missing values
status The label used for plotting, combining the independence and missing value information for a case as appropriate.

Examples

# Create an example data frame with missing values
cy <- state_panel(as.Date("1980-06-30"), as.Date("2015-06-30"), by = "year", useGW = TRUE)
polity

Polity IV combined Polity scores

Description

Polity scores reflect how democratic or autocratic countries are from a scale of -10 (autocratic) to 10 (democratic). There are also three special codes for foreign "interruption" (-66), anarchy (-77), and transition periods (-88).

The data are included here for as an example for use with the missing plot. Thus they do not contain all available Polity indicators, which are available at the Polity project website www.systemicpeace.org.
Usage

polity

Format

Data frame

ccode  Correlates of War (COW) country code.
year   Year of the observation.
polity Combined Polity score.

Source

Examples

data("polity")
head("polity")

Description

Shorten country names

Usage

prettyc(x)

Arguments

x  (character())

Country names, e.g. from country_names().

Examples

cn <- c("Macedonia, the former Yugoslav Republic of",
        "Congo, the Democratic Republic of the",
        "Tanzania, United Republic of")
prettyc(cn)
**sfind**  
*Lookup country codes or names*

**Description**  
Helper to look up state list entries by country code or name

**Usage**  
```
sfind(x, list = "both")
```

**Arguments**  
- **x**: The search string or number.  
- **list**: Which state list to search (both, GW, or COW only)

**Examples**  
- # Works with either integer or strings  
sfind(325)  
sfind("ALG")  
sfind("Algeria")

- # Search strings are treated as regular expressions (see stringr::str_detect)  
sfind("Germany")  
sfind("German")

**states**  
*State system membership*

**Description**  
Create data based on the Gleditsch & Ward (G&W) or Correlates of War (COW) state system memberships lists. This is useful as a template for merging other sources of data that have conflicting sets of states.

**Details**  
See static docs at https://andybeger.com/states and the source code at https://www.github.com/andybega/states

**References**  

state_panel

Create state panel data

Description
Create panel data consisting of independent states in the international system.

Usage
state_panel(start, end, by = NULL, partial = "any", useGW = TRUE)

Arguments
- **start**: Beginning date for data, see `parse_date()` for format options.
- **end**: End date for data, see `parse_date()` for format options.
- **by**: Temporal resolution, "year", "month", or "day". If NULL, inferred from start and end input format, e.g. `start = 2006` implies by = "year".
- **partial**: Option for how to handle edge cases where a state is independent for only part of a time period (year, month, etc.). Options include "exact", "first", "last", and "any". See details.
- **useGW**: Use Gleditsch & Ward statelist or Correlates of War state system membership list.

Details
The partial option determines how to handle instances where a country gains or loses independence during a time period specified in the by option:

- "exact": the exact date in start is used for filtering
- "any": a state-period is included if the state was independent at any point in that period.
- "first": same as "exact" with the first date in a time period, e.g. "2006-01-01".
- "last": last date in a period. For "yearly" data, this is the same as "exact" with a start date like "YYYY-12-21", but for calendar months the last date varies, hence the need for this option.

Value
A `base::data.frame()` with 2 columns for the country code and date information. The column names and types differ slightly based on the "useGW" and "by" arguments.

- The first column will be "gwcode" if `useGW = TRUE` (the default), and "cowcode" otherwise.
- The second column is an integer vector with name "year" for country-year data (if by or the inferred by value is "year"), and a `base::Date()` vector with the name "date" otherwise.
Examples

# Basic usage with full option set specified:
gwlist <- state_panel("1991-01-01", "2015-01-01", by = "year",
                      partial = "any", useGW = TRUE)
head(gwlist, 3)
                      partial = "any", useGW = FALSE)
head(cowlist, 3)

# For yearly data, a proper date is not needed, and by = "year" and
# partial = "any" are inferred.
gwlist <- state_panel(1990, 1995)
sfind(265, list = "GW")
265 %in% gwlist$gwcode

# Partials
# Focus on South Sudan--is there a record for 2011, first year of independence?
data(gwstates)
dplyr::filter(gwstates, gwcode==626)

# No 2011 because SSD was not independent on January 1st 2011
x <- state_panel(2011, 2013, partial = "first")
dplyr::filter(x, gwcode==626)

# Includes 2011 because 12-31 date is used for filtering
x <- state_panel("2011-12-31", "2013-12-31", by = "year", partial = "exact")
dplyr::filter(x, gwcode==626)

# Includes 2011 because partial = "any"
x <- state_panel("2011-01-01", "2013-01-01", by = "year", partial = "any")
dplyr::filter(x, gwcode==626)
