Package ‘wkb’

December 5, 2019

Type  Package
Title  Convert Between Spatial Objects and Well-Known Binary Geometry
Version  0.4-0
Imports  sp
Suggests  testthat
Author  TIBCO Software Inc.
Maintainer  Ian Cook <ianmcook@gmail.com>
Description  Utility functions to convert between the 'Spatial' classes
specified by the package 'sp', and the well-known binary 'WKB' representation
for geometry specified by the 'Open Geospatial Consortium'.
Supports 'Spatial' objects of class 'SpatialPoints', 'SpatialPointsDataFrame', 'SpatialLines', 'SpatialLinesDataFrame', 'SpatialPolygons', and 'SpatialPolygonsDataFrame'.
Supports 'WKB' geometry types 'Point', 'LineString', 'Polygon', 'MultiPoint', 'MultiLineString', and 'MultiPolygon'.
Includes extensions to enable creation of maps with 'TIBCO Spotfire'.

hex2raw

Convert String Hex Representation to Raw Vector

Description

Converts a string hexadecimal representation to a raw vector.

Usage

hex2raw(hex)

Arguments

hex character string or character vector containing a hexadecimal representation.

Details

Non-hexadecimal characters are removed.

Value

A raw vector.

The return value is a list of raw vectors when the argument hex contains more than one hexadecimal representation.

See Also

raw2hex in package PKI, readWKB

Examples

# create a character string containing a hexadecimal representation
hex <- c("0101000000000000000000f03f00000000000840"

# convert to raw vector
wkb <- hex2raw(hex)

# create a character vector containing a hexadecimal representation
hex <- c("01", "01", "00", "00", "00", "00", "00", "00", "00", "00", "00", "00", "00", "00", "00", "00", "f0", "3f", "00", "00", "00", "00", "00", "00", "00", "08", "40")

# convert to raw vector
wkb <- hex2raw(hex)

# create vector of two character strings each containing a hex representation
hex <- c("0101000000000000000000f03f00000000000840",

"0101000000000000000000f03f00000000000840")
# readWKB

## Convert WKB to Spatial Objects

### Description

Converts well-known binary (WKB) geometry representations to Spatial objects.

### Usage

```
readWKB(wkb, id = NULL, proj4string = CRS(as.character(NA)))
```

### Arguments

- `wkb` list in which each element is a raw vector consisting of a WKB geometry representation.
- `id` character vector of unique identifiers of geometries. The length of `id` must be the same as the length of the `wkb` list.
- `proj4string` projection string of class CRS.

### Details

Supported WKB geometry types are Point, LineString, Polygon, MultiPoint, MultiLineString, and MultiPolygon. All elements in the list must have the same WKB geometry type. The WKB geometry representations may use little-endian or big-endian byte order.

The argument `wkb` may also be a raw vector consisting of one WKB geometry representation. In that case, the argument `id` must have length one.

### Value

An object inheriting class Spatial.

The return value may be an object of class SpatialPoints, SpatialLines, SpatialPolygons, or a list in which each element is an object of class SpatialPoints. The class of the return value depends on the WKB geometry type as shown in the table below.

<table>
<thead>
<tr>
<th>Type of WKB geometry</th>
<th>Class of return value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>SpatialPoints</td>
</tr>
<tr>
<td>LineString</td>
<td>SpatialLines</td>
</tr>
<tr>

writeEnvelope

Envelope of Spatial Objects

Description

Takes a Spatial object and returns a data frame with six columns representing the envelope of each
 element in the Spatial object.

Usage

writeEnvelope(obj, centerfun = mean)

Arguments

obj
  object inheriting class Spatial.

centerfun
  function to apply to the x-axis limits and y-axis limits of the bounding box to
  obtain the x-coordinate and y-coordinate of the center of the bounding box.

Details

obj may be an object of class SpatialPoints, SpatialPointsDataFrame, SpatialLines, SpatialLinesDataFrame,
SpatialPolygons, or SpatialPolygonsDataFrame, or a list in which each element is an object
of class SpatialPoints or SpatialPointsDataFrame.
Value

A data frame with six columns named XMax, XMin, YMax, YMin, XCenter, and YCenter. The first four columns represent the corners of the bounding box of each element in obj. The last two columns represent the center of the bounding box of each element in obj. The number of rows in the returned data frame is the same as the length of the argument obj.

When this function is run in TIBCO Enterprise Runtime for R (TERR), the columns of the returned data frame have the SpotfireColumnMetaData attribute set to enable TIBCO Spotfire to recognize them as containing envelope information.

Example usage at writeWKB

---

**writeWKB**  
*Convert Spatial Objects to WKB*

**Description**

Converts Spatial objects to well-known binary (WKB) geometry representations.

**Usage**

```r
writeWKB(obj, endian = "little")
```

**Arguments**

- `obj` object inheriting class `Spatial`.
- `endian` The byte order ("big" or "little") for encoding numeric types. The default is "little".

**Details**

The argument `obj` may be an object of class `SpatialPoints`, `SpatialPointsDataFrame`, `SpatialLines`, `SpatialLinesDataFrame`, `SpatialPolygons`, or `SpatialPolygonsDataFrame`, or a list in which each element is an object of class `SpatialPoints` or `SpatialPointsDataFrame`.

**Value**

A list with class AsIs. The length of the returned list is the same as the length of the argument `obj`. Each element of the returned list is a `raw` vector consisting of a WKB geometry representation. The WKB geometry type depends on the class of `obj` as shown in the table below.

<table>
<thead>
<tr>
<th>Class of obj</th>
<th>Type of WKB geometry</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SpatialPoints</code> or <code>SpatialPointsDataFrame</code></td>
<td>Point</td>
</tr>
<tr>
<td>list of <code>SpatialPoints</code> or <code>SpatialPointsDataFrame</code></td>
<td>MultiPoint</td>
</tr>
<tr>
<td><code>SpatialLines</code> or <code>SpatialLinesDataFrame</code></td>
<td>MultiLineString</td>
</tr>
<tr>
<td><code>SpatialPolygons</code> or <code>SpatialPolygonsDataFrame</code></td>
<td>Polygon or MultiPolygon</td>
</tr>
</tbody>
</table>
A SpatialPolygons or SpatialPolygonsFrame object is represented as WKB Polygons if each Polygons object within it represents a single polygon; otherwise it is represented as WKB MultiPolygons.

The byte order of numeric types in the returned WKB geometry representations depends on the value of the argument `endian`. Little-endian byte order is known as NDR encoding, and big-endian byte order is known as XDR encoding.

When this function is run in TIBCO Enterprise Runtime for R (TERR), the return value has the `SpotfireColumnMetaData` attribute set to enable TIBCO Spotfire to recognize it as a WKB geometry representation.
